- 1. Diazepam.** Onset of action is fast after intravenous (IV) injection, but slow to intermediate after oral or rectal administration. The half-life is greater than 24 hours, although anticonvulsant effects and sedation are often shorter as a result of redistribution from the central nervous system.

2. **Lorazepam.** Onset is intermediate after intramuscular (IM) dosing. The elimination half-life is 10–20 hours, and anticonvulsant effects are generally longer than for diazepam.
3. **Midazolam.** Onset is rapid after intramuscular or intravenous injection and intermediate after nasal application or ingestion. The half-life is 1.5–3 hours and the duration of effects is very short due to rapid redistribution from the brain. However, sedation may persist for 10 hours or longer after prolonged infusions due to saturation of peripheral sites and slowed redistribution.

II. Indications

- A. **Anxiety and agitation.** Benzodiazepines are often used for the treatment of anxiety or agitation (eg, caused by sympathomimetic or hallucinogenic drug intoxication).
- B. **Convulsions.** All three drugs can be used for the treatment of acute seizure activity or status epilepticus resulting from idiopathic epilepsy or convulsant drug overdose. Midazolam and lorazepam have the advantage of rapid absorption after intramuscular injection. Lorazepam also has a longer duration of anticonvulsant action than the other two agents.
- C. **Muscle relaxant.** These drugs can be used for relaxation of excessive muscle rigidity and contractions (eg, caused by strychnine poisoning or black widow spider envenomation or rigidity syndromes with hyperthermia or dyskinesias or tetanus).
- D. **Chloroquine poisoning.** Diazepam may antagonize cardiotoxicity.
- E. **Alcohol or sedative-hypnotic withdrawal.** Diazepam and lorazepam are used to abate symptoms and signs of alcohol and hypnosedative withdrawal (eg, anxiety, tremor, and seizures).
- F. **Conscious sedation.** Midazolam is used to induce sedation and amnesia during brief procedures and in conjunction with neuromuscular paralysis for endotracheal intubation.

III. **Contraindications.** Do not use in patients with a known sensitivity to benzodiazepines.

IV. Adverse effects

- A. Central nervous system–depressant effects may interfere with evaluation of neurologic function.
- B. Excessive or rapid intravenous administration may cause respiratory arrest.
- C. The drug may precipitate or worsen hepatic encephalopathy.
- D. Rapid or large-volume IV administration may cause cardiotoxicity similar to that seen with phenytoin (see p 303) because of the diluent propylene glycol. Continuous infusions with this vehicle may result in a hyperlactatemia, increased osmolar gap, and renal dysfunction. Several products also contain up to 2% benzyl alcohol as a preservative.
- E. **Use in pregnancy.** FDA category D. All of these drugs readily cross the placenta. However, this does not preclude their acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A. Benzodiazepines will potentiate the central nervous system–depressant effects of opioids, ethanol, and other sedative-hypnotic and depressant drugs.
- B. **Flumazenil** (see p 446) will reverse the effects of benzodiazepines and may trigger an acute abstinence syndrome in patients using the drugs chronically. Patients who have received flumazenil will have an unpredictable but reduced or absent response to benzodiazepines.
- C. Diazepam may produce a false-positive glucose reaction with Clinistix and Diastix test strips.

VI. Dosage and method of administration

A. Anxiety or agitation; muscle spasm or hyperactivity

1. **Diazepam.** Give 0.1–0.2 mg/kg (usual doses: children >5 years and adults 2–10 mg; children >30 days to 5 years 1–2 mg) IV initially (no faster than 5 mg/min in adults; administer over 3 minutes in children), depending on severity (tetanus requires higher doses); may repeat every 1–4 hours

as needed. The oral dose is 0.1–0.3 mg/kg (adults 2–10 mg; lower doses for geriatric patients not to exceed 2.5 mg and less frequent intervals; children > 6 months 1–2.5 mg). Do **not** give intramuscularly. Doses should be adjusted to tolerance and response.

2. **Lorazepam.** Give 1–2 mg (children: 0.04 mg/kg IV) not to exceed 2 mg/min, or 0.05 mg/kg IM (maximum 4 mg). The usual adult oral dose is 2–6 mg daily.
 3. **Midazolam.** Give 0.05 mg/kg (up to 0.35 mg/kg for anesthesia induction) IV over 20–30 seconds (usual adult doses vary 1 mg to maximum of 5 mg given in increments of 2.5 mg every 2 minutes; lower dose in geriatric patients with maximum at 3.5 mg) or 0.07–0.1 mg/kg IM. Repeat after 10–20 minutes if needed. Continuous infusions have also been used to maintain effect with initial rates of 0.02–0.1 mg/kg/h (usual adult dose 1–7 mg/h; children 1–2 mcg/kg/min) and then titrated to effect. **Caution:** There have been several reports of respiratory arrest and hypotension after rapid intravenous injection, especially when midazolam is given in combination with opioids. Prolonged continuous infusion may lead to persistent sedation after the drug is discontinued because midazolam accumulates in tissues.
- B. Convulsions. Note:** If convulsions persist after initial doses of benzodiazepines, consider alternate anticonvulsant drugs such as phenobarbital (see p 486), phenytoin (p 488), pentobarbital (p 485), or propofol (p 494). Also, see treatment of seizures (p 22).
1. **Diazepam.** Give 0.1–0.2 mg/kg IV, not to exceed 5 mg/min, every 5–10 minutes (usual initial doses: adult, 5–10 mg; children ≥5 years, 1–2 mg; children ≤5 years, 0.2–0.5 mg), to a maximum total of 30 mg (adults) or 5 mg (young children) or 10 mg (older children).
 2. **Lorazepam.** Give 1–2 mg (neonates, 0.05–0.1 mg/kg; older children, 0.04 mg/kg) IV, not to exceed 2 mg/min; repeat if needed after 5–10 minutes. Usual dose for status epilepticus is up to 4 mg slow IV push over 2 minutes (dilute with an equal volume of saline). The drug can also be given IM (0.05 mg/kg, maximum 4 mg), with onset of effects after 6–10 minutes.
 3. **Midazolam.** Give 0.05 mg/kg (up to 0.2 mg/kg for refractory status epilepticus) IV over 20–30 seconds, or 0.1–0.2 mg/kg IM; this may be repeated if needed after 5–10 minutes or maintained with a continuous infusion (see note above). The drug is rapidly absorbed after IM injection and can be used when IV access is not readily available.
- C. Chloroquine and hydroxychloroquine intoxication.** There is reported improvement of cardiotoxicity with **high-dose** administration of **diazepam** at 1–2 mg/kg IV (infuse over 30 minutes) followed by an infusion of 2 mg/kg/24 hours. **Caution:** This will likely cause apnea; the patient must be intubated, and ventilation must be controlled.
- E. Alcohol withdrawal syndrome**
1. **Diazepam.** Administer 5–10 mg IV initially, then 5 mg every 10 minutes until the patient is calm. Large doses may be required to sedate patients with severe withdrawal. The oral dose is 10–20 mg initially, repeated every 1–2 hours until calm.
 2. **Lorazepam.** Administer 1–2 mg IV initially, then 1 mg every 10 minutes until the patient is calm. Large doses may be required to sedate patients in severe withdrawal. The oral dose is 2–4 mg, repeated every 1–2 hours until calm.

VII. Formulations

A. Parenteral

1. **Diazepam** (Valium, others): 5-mg/mL solution, 2-mL prefilled syringes.
2. **Lorazepam** (Ativan, others): 2- and 4-mg/mL solutions; 1 mL in 2-mL syringe for dilution.
3. **Midazolam** (Versed): 1- and 5-mg/mL solutions; 1-, 2-, 5-, and 10-mL vials.

B. Oral

1. **Diazepam** (Valium, others): 2-, 5-, and 10-mg tablets.
2. **Lorazepam** (Ativan, others): 0.5-, 1-, and 2-mg tablets; 2 mg/mL oral solution.

C. Suggested minimum stocking levels to treat a 70-kg adult for the first 24 hours:

1. **Diazepam**, 200 mg.
2. **Lorazepam**, 24 mg.
3. **Midazolam**, 50 mg (two vials of 5 mg/mL, 5 mL each, or equivalent).

► BENZTROPINE

Thomas E. Kearney, PharmD

I. Pharmacology. Benztropine is an antimuscarinic agent with pharmacologic activity similar to that of atropine. The drug also exhibits antihistaminic properties. Benztropine is used for the treatment of parkinsonism and for the control of extrapyramidal side effects associated with neuroleptic use.

II. Indications. Benztropine is an alternative in adults to diphenhydramine (the drug of choice for children) for the treatment of acute dystonic reactions associated with neuroleptics or metoclopramide. **Note:** It is not effective for tardive dyskinesia or neuroleptic malignant syndrome (see p 22).

III. Contraindications

- A. Angle-closure glaucoma.
- B. Obstructive uropathy (prostatic hypertrophy).
- C. Myasthenia gravis.
- D. Not recommended for children under 3 years by manufacturer; alternately, use diphenhydramine (see p 436) or consider benztropine if the patient is unresponsive or hypersensitive to diphenhydramine and is experiencing a severe or life-threatening situation (eg, dystonic laryngeal or pharyngeal spasms).
- E. Tardive dyskinesia
- F. Known hypersensitivity

IV. Adverse effects

- A. Adverse effects include sedation, blurred vision, tachycardia, urinary hesitancy or retention, and dry mouth. Adverse effects are minimal after single doses.
- B. **Use in pregnancy.** FDA category C (indeterminate). However, this does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A. Benztropine has additive effects with other drugs exhibiting antimuscarinic properties (eg, antihistamines, phenothiazines, cyclic antidepressants, and disopyramide).
- B. Slowing of gastrointestinal motility may delay or inhibit absorption of certain drugs.

VI. Dosage and method of administration

- A. **Parenteral.** Give 1–2 mg IV or IM (children ≥ 3 years old, 0.02 mg/kg and 1 mg maximum). May repeat dose in 15 minutes if unresponsive.
- B. **Oral.** Give 1–2 mg PO every 12 hours (children ≥ 3 years old, 0.02 mg/kg and 1 mg maximum) for 2–3 days to prevent recurrence of symptoms. Maximum recommended dose for adults is 6 mg/day.

VII. Formulations

- A. **Parenteral.** Benztropine mesylate (Cogentin), 1 mg/mL, 2-mL ampules.
- B. **Oral.** Benztropine mesylate (Cogentin), 0.5-, 1-, and 2-mg tablets.
- C. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 6 mg (three ampules, 2 mL each).

► BICARBONATE, SODIUM

Thomas E. Kearney, PharmD

I. Pharmacology

- A. Sodium bicarbonate is a buffering agent that reacts with hydrogen ions to correct acidemia and produce alkalemia. Urinary alkalization from renally excreted bicarbonate ions enhances the renal elimination of certain acidic drugs (eg, salicylate, chlorpropamide, chlorophenoxy herbicides, and phenobarbital) and helps prevent renal tubular damage from deposition of myoglobin in patients with rhabdomyolysis as well as from precipitation (by enhancing solubility) of methotrexate with high-dose therapy. In addition, maintenance of a normal or high serum pH may prevent intracellular distribution of salicylate and formate (toxic metabolite of methanol).
- B. The sodium ion load and alkalemia produced by hypertonic sodium bicarbonate reverse the sodium channel–dependent membrane-depressant (“quinidine-like”) effects of several drugs (eg, tricyclic antidepressants, type Ia and type Ic antiarrhythmic agents, propranolol, propoxyphene, cocaine, and diphenhydramine).
- C. Alkalinization causes an intracellular shift of potassium and is used for the acute treatment of hyperkalemia.
- D. Sodium bicarbonate given orally or by gastric lavage forms an insoluble salt with iron and may theoretically help prevent absorption of ingested iron tablets (unproved).
- E. Neutralization of acidic substances to prevent caustic injury is usually not recommended due to the potential for an exothermic reaction, generation of gas, and lack of evidence that tissue injury is minimized.

II. Indications

- A. Severe metabolic acidosis resulting from intoxication by methanol, ethylene glycol, or salicylates or from excessive lactic acid production (eg, resulting from status epilepticus or shock).
- B. To produce urinary alkalization, to enhance elimination of certain acidic drugs (salicylate, phenobarbital, chlorpropamide, chlorophenoxy herbicides-2,4-D), and to prevent nephrotoxicity from the renal deposition of myoglobin after severe rhabdomyolysis or precipitation of methotrexate. (While enhanced elimination may be achieved, it is uncertain if clinical outcomes are improved with this therapy.) Also recommended by REAC/TS for internal contamination of uranium from radiation emergencies to prevent acute tubular necrosis (see Radiation, p 327).
- C. Cardiotoxicity with impaired ventricular depolarization (as evidenced by a prolonged QRS interval) caused by tricyclic antidepressants, type Ia or type Ic antiarrhythmics, and other membrane-depressant drugs (see Table II-7, p 88). **Note:** *Not effective* for dysrhythmias associated with abnormal repolarization (prolonged QT interval and torsade de pointes).

III. Contraindications. The following contraindications are relative:

- A. Significant metabolic or respiratory alkalemia or hyponatremia.
- B. Severe pulmonary edema associated with volume overload.
- C. Intolerance to sodium load (renal failure, CHF).

IV. Adverse effects

- A. Excessive alkalemia: impaired oxygen release from hemoglobin, hypocalcemic tetany, and paradoxical intracellular acidosis (from elevated $p\text{CO}_2$ concentrations) and hypokalemia.
- B. Hyponatremia and hyperosmolality. Caution with rapid infusion of hypertonic solutions in neonates and young children.
- C. Aggravation of congestive heart failure and pulmonary edema.
- D. Extravasation leading to tissue inflammation and necrosis (product is hypertonic).
- E. May exacerbate QT prolongation and associated dysrhythmias (eg, torsade de pointes) as a result of electrolyte shifts (hypokalemia).

- F. Use in pregnancy.** FDA category C (indeterminate). However, this does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).
- V. Drug or laboratory interactions.** Do not mix with other parenteral drugs because of the possibility of drug inactivation or precipitation.
- VI. Dosage and method of administration (adults and children)**
- A. Metabolic acidemia.** Give 0.5–1 mEq/kg IV bolus; repeat as needed to correct serum pH to at least 7.2. For salicylates, methanol, or ethylene glycol, raise the pH to at least 7.4–7.5.
- B. Urinary alkalization.** Give 44–100 mEq in 1 L of 5% dextrose in 0.25% normal saline or 88–150 mEq in 1 L of 5% dextrose at 2–3 mL/kg/h (adults 150–200 mL/h). Check urine pH frequently and adjust flow rate to maintain urine pH level at 7–8. **Note:** Hypokalemia and fluid depletion prevent effective urinary alkalization: add 20–40 mEq of potassium to each liter, unless renal failure is present. Prevent excessive systemic alkalemia (keep blood pH < 7.55) and hypernatremia. Monitor urine pH and serum electrolytes hourly.
- C. Cardiotoxic (“membrane-stabilizing”) drug intoxication.** Give 1–2 mEq/kg IV bolus over 1–2 minutes; repeat as needed to improve cardiotoxic manifestations (eg, prolonged QRS interval, wide-complex tachycardia, hypotension) and to maintain serum pH at 7.45–7.55. There is no evidence that constant infusions are as effective as boluses given as needed.
- VII. Formulations**
- A.** Several products are available, ranging from 4.2% (0.5 mEq/mL preferred for neonates and young children) to 7.5% (0.89 mEq/mL) to 8.4% (1 mEq/mL) in volumes of 10–500 mL. The most commonly used formulation available in most emergency “crash carts” is 8.4% (“hypertonic”) sodium bicarbonate, 1 mEq/mL, in 50-mL ampules or prefilled syringes.
- B.** The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 10 ampules or syringes (approximately 500 mEq).

► BOTULINUM ANTITOXIN

Thomas E. Kearney, PharmD

- I. Pharmacology.** Botulinum antitoxin contains concentrated equine-derived antibodies directed against the toxins produced by the various strains of *Clostridium botulinum* (A, B, and E). The antitoxin is currently available as the bivalent (A, B) and monovalent (E) forms. The monovalent (E) form provides coverage for botulism from fish sources and is available only through an investigational new drug (IND) protocol. (A monovalent antitoxin against the rare type F botulism is available only under IND protocol. If type F is suspected, the CDC advises that there is variable cross-reactivity with type E antitoxin.) The antibodies bind and inactivate freely circulating botulinum toxins but do **not** remove toxin that is already bound to nerve terminals. Because antitoxin will not reverse established paralysis once it occurs, it must be administered before paralysis sets in. Treatment within 24 hours of the onset of symptoms may shorten the course of intoxication and prevent progression to total paralysis.
- II. Indications.** Botulinum antitoxin is used to treat clinical botulism (see page 136) to prevent progression of neurologic manifestations. It is generally not recommended for treatment of infant botulism; however, open-label clinical trials have been under way in California with human-derived botulism immune globulin (BIG) and have been extended nationwide. For information, call the California Department of Health Services at (510) 231-7600.
- III. Contraindications.** No absolute contraindications. Known hypersensitivity to botulinum antitoxin or horse serum requires extreme caution if this product is given.

IV. Adverse effects

- A.** Immediate hypersensitivity reactions (anaphylaxis) resulting from the equine source of antibodies.
- B. Use in pregnancy.** There are no data on teratogenicity. Anaphylactic reaction resulting in shock or hypoxemia in the mother could conceivably adversely affect the fetus.

V. Drug or laboratory interactions. No known interactions.**VI. Dosage and method of administration**

- A.** For suspected or established clinical botulism, give one 10-mL vial diluted 1:10 in 0.9% saline (normal saline) and administer by slow IV infusion. A second vial may be administered in 2 to 4 hours if signs or symptoms worsen, but is usually not necessary as the neutralizing antibodies far exceed the levels of circulating toxin.
- B.** Perform a skin test prior to administration according to the package instructions. Should the patient have known sensitivity to horse serum or demonstrate a positive skin test, provide desensitization as indicated in the package insert. Even if the skin test is negative, anaphylaxis may still occur unpredictably. Pretreat the patient with diphenhydramine (see p 436), 1–2 mg/kg IV, and cimetidine, 300 mg IV (or other H₂ blocker, p 428), and have epinephrine (p 442) ready in case anaphylaxis occurs.

VII. Formulations

- A. Parenteral.** Bivalent botulinum antitoxin or botulism antitoxin bivalent (equine) (7500 IU type A, 5500 IU type B), and monovalent botulinum antitoxin (8500 IU type E); available through the Centers for Disease Control (CDC), telephone (404) 639-3356 (weekdays) or (404) 639-2888 (after hours) or contact your local health department (for reporting and to facilitate access to antitoxin). To obtain or determine the availability of BIG for suspected infant botulism, call (510) 231-7600.
- B. Suggested minimum stocking level.** Not relevant—available only through federal (CDC) or state (California) government.

► BRETYLIUM

Thomas E. Kearney, PharmD

- I. Pharmacology.** Bretylium is a quaternary ammonium compound that is an effective type III antifibrillatory drug and also suppresses ventricular ectopic activity. It increases the threshold for ventricular fibrillation and reduces the disparity in action potential duration between normal and ischemic tissue, which is believed to abolish boundary currents responsible for reentrant arrhythmias. Its pharmacologic actions are complex. Initially, norepinephrine is released from sympathetic neurons; this is followed by a block of further norepinephrine release. In addition, norepinephrine uptake is inhibited at adrenergic neurons. The result is a transient increase in heart rate, blood pressure, and cardiac output that may last from a few minutes to 1 hour. Subsequent adrenergic blockade produces vasodilation, which may result in hypotension.

II. Indications

- A. Prophylaxis and treatment of ventricular fibrillation.** Bretylium may be particularly effective in hypothermic patients.
- B. Ventricular tachycardia resistant to other antiarrhythmic agents.** However, it has not been proved beneficial for drug- or chemical-induced ventricular dysrhythmias.

III. Contraindications

- A.** Use with extreme caution in patients with intoxication by digitalis, chloral hydrate, or halogenated hydrocarbons, because the initial release of catecholamines may aggravate arrhythmias.

- B. Use with extreme caution in patients with arrhythmias caused by intoxication with cyclic antidepressants or type Ia or type Ic antiarrhythmic agents because of additive cardiac depression.
- C. Use with extreme caution in patients with severe pulmonary hypertension or aortic stenosis.
- D. Not recommended for children under 12 years old.

IV. Adverse effects

- A. Hypotension (both supine and orthostatic).
- B. Nausea and vomiting from rapid intravenous administration.
- C. Transient hypertension and worsening of arrhythmias may be caused by initial catecholamine release.
- D. **Use in pregnancy.** FDA category C (indeterminate). However, this does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A. The pressor effect of sympathomimetic amines may be enhanced with initial catecholamine release.
- B. Cardiac-depressant effects may be additive with other antiarrhythmic drugs, particularly type Ia and type Ic drugs.

VI. Dosage and method of administration

- A. **For ventricular fibrillation**, give 5 mg/kg IV over 1 minute (in addition to cardiopulmonary resuscitation and defibrillation). If not effective, administration may be repeated with 10 mg/kg.
- B. **For ventricular tachycardia**, give adults and children older than 12 years 5–10 mg/kg IV over 8–10 minutes or IM, repeated as necessary at 15-minute intervals to a maximum dose of 30 mg/kg; repeat every 6 hours as needed.
- C. **The continuous infusion rate** after the loading dose is 1–2 mg/min (children ≥ 12 years old, 20–30 mcg/kg/min).

VII. Formulations

- A. **Parenteral.** Bretylium tosylate (Bretylol, others), 50 mg/mL: 10-mL ampules, vials, and syringes; 500 and 1000 mg premixed in 250-mL 5% dextrose solutions.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is six 10-mL vials.

► BROMOCRIPTINE

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Bromocriptine mesylate is a semisynthetic derivative of the ergopeptide group of ergot alkaloids with dopaminergic agonist effects. It also has minor α -adrenergic antagonist properties. The dopaminergic effects account for its inhibition of prolactin secretion and its beneficial effects in the treatment of parkinsonism, neuroleptic malignant syndrome (NMS; see p 22), and cocaine craving, as well as its adverse effect profile and drug interactions. A key limitation is the inability to administer bromocriptine by the parenteral route coupled with poor bioavailability (only about 6% of an oral dose is absorbed). In addition, the onset of therapeutic effects (eg, alleviation of muscle rigidity, hypertension, and hyperthermia) in the treatment of NMS may take several hours to days.
- II. **Indications**
 - A. Treatment of NMS caused by neuroleptic drugs (eg, haloperidol and other antipsychotics) or levodopa withdrawal. **Note:** If the patient has significant hyperthermia (eg, rectal or core temperature $\geq 40^\circ\text{C}$), bromocriptine should be considered secondary and adjunctive therapy to immediate measures such as neuromuscular paralysis and aggressive external cooling.

- B. Bromocriptine has been used experimentally to alleviate craving for cocaine.
Caution: There is one case report of a severe adverse reaction (hypertension, seizures, and blindness) when bromocriptine was used in a cocaine abuser during the postpartum period.
- C. **Note:** Bromocriptine is **not** considered appropriate first-line therapy for acute drug-induced extrapyramidal or parkinsonian symptoms (see p 25).

III. Contraindications

- A. Uncontrolled hypertension or toxemia of pregnancy.
- B. Known hypersensitivity to the drug.
- C. A relative contraindication is a history of angina, myocardial infarction, stroke, vasospastic disorders (eg, Raynaud's disease), or bipolar affective disorder. In addition, there is no published experience in children less than 7 years old. Children may achieve higher blood levels and require lower doses.

IV. Adverse effects.

Most adverse effects are dose-related and of minor clinical consequence; some are unpredictable.

- A. The most common side effect is nausea. Epigastric pain, dyspepsia, and diarrhea also have been reported.
- B. Hypotension (usually transient) and syncope may occur at the initiation of treatment, and hypertension may occur later. Other cardiovascular effects include dysrhythmias (with high doses), exacerbation of angina and vasospastic disorders such as Raynaud's disease, and intravascular thrombosis resulting in acute myocardial infarction (one case report).
- C. Nervous system side effects vary considerably and include headache, drowsiness, fatigue, hallucinations, mania, psychosis, agitation, seizures, and cerebrovascular accident. Multiple interrelated risk factors include dose, concurrent drug therapy, and preexisting medical and psychiatric disorders.
- D. Rare effects include pulmonary toxicity (infiltrates, pleural effusion, and thickening) and myopia with long-term, high-dose treatment (months). There has been one case of retroperitoneal fibrosis.
- E. Sulfite preservatives in some preparations may cause hypersensitivity reactions. SnapTabs tablets do not contain sulfites.
- F. **Use in pregnancy.** FDA category B (see p 405). This drug has been used therapeutically during the last trimester of pregnancy for treatment of a pituitary tumor. It has been shown to inhibit fetal prolactin secretion, and it may precipitate premature labor and inhibit lactation in the mother.

V. Drug or laboratory interactions

- A. Bromocriptine may accentuate hypotension in patients receiving antihypertensive drugs.
- B. Theoretically, this drug may have additive effects with other ergot alkaloids, and its potential to cause peripheral vasospasm may be exacerbated by propranolol.
- C. Bromocriptine may reduce ethanol tolerance.
- D. There has been one case report of apparent serotonin syndrome (see p 22) in a patient with Parkinson's disease receiving levodopa and carbidopa.

VI. Dosage and method of administration for NMS.

In adults, administer 2.5–10 mg orally or by gastric tube 3–4 times daily (average adult dose 5 mg every 8 hours). May increase to a maximum of 20 mg every 6 hours. The pediatric dose is unknown (one case report of 0.08 mg/kg every 8 hours in a 7-year-old—tablets were mixed in a 2.5-mg/10 mL slurry and given by feeding tube). Use small, frequent dosing to minimize nausea.

- A. A therapeutic response is usually achieved with total daily doses of 5–30 mg.
- B. Continue treatment for 7–10 days after control of rigidity and fever, then slowly taper the dose over 3 days (to prevent recurrence). Several days of therapy may be required for complete reversal of NMS.

VII. Formulations

- A. **Oral.** Bromocriptine mesylate (Parlodel, others), 2.5- and 5-mg capsules and scored (SnapTabs) tablets.

- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 30 mg, or one 30-tablet (SnapTabs) package. SnapTabs tablets do not contain sulfite preservatives.

► CALCIUM

Binh T. Ly, MD

I. Pharmacology

- A. Calcium is a cation necessary for the normal functioning of a variety of enzymes and organ systems, including muscle and nerve tissue. Hypocalcemia, or a blockade of calcium's effects, may cause muscle cramps, tetany, and ventricular fibrillation. Antagonism of calcium-dependent channels results in hypotension, bradycardia, and atrioventricular block.
- B. Calcium ions rapidly bind to fluoride ions, abolishing their toxic effects.
- C. Calcium can reverse the negative inotropic effects of calcium antagonists; however, depressed automaticity and atrioventricular nodal conduction velocity and vasodilation may not respond to calcium administration.
- D. Calcium stabilizes cardiac cell membranes in hyperkalemic states.

II. Indications

- A. Symptomatic hypocalcemia resulting from intoxication by fluoride, oxalate, or the intravenous anticoagulant citrate.
- B. Hydrofluoric acid exposure (see p 221).
- C. Hypotension in the setting of calcium antagonist (eg, verapamil) overdose (see p 144).
- D. Severe hyperkalemia with cardiac manifestations (relatively contraindicated in the setting of digitalis toxicity, see III.B, below).
- E. Symptomatic hypermagnesemia.

III. Contraindications

- A. Hypercalcemia.
- B. Although controversial, calcium is relatively contraindicated in the setting of intoxication with cardiac glycosides (**may** aggravate digitalis-induced ventricular tachydysrhythmias) and should be reserved for life-threatening situations.
- C. **Note:** Calcium *chloride* salt should **not** be used for intradermal, subcutaneous, or intra-arterial injection because it is too concentrated and may result in further tissue damage.

IV. Adverse effects

- A. Tissue irritation, particularly with calcium chloride salt; extravasation may cause local irritation or necrosis.
- B. Hypercalcemia, especially in patients with diminished renal function.
- C. Hypotension, bradycardia, syncope, and cardiac dysrhythmias caused by rapid intravenous administration.
- D. Constipation caused by orally administered calcium salts.
- E. **Use in pregnancy.** FDA category C (indeterminate). This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A. Inotropic and arrhythmogenic effects of digitalis are potentiated by calcium.
- B. A precipitate will form with solutions containing soluble salts of carbonates, phosphates, or sulfates and with various antibiotics.

- VI. **Dosage and method of administration.** **Note:** Calcium chloride contains nearly three times the amount of Ca^{2+} per milliliter of 10% solution compared with the same concentration of calcium gluconate.

- A. **Oral fluoride ingestion.** Administer calcium-containing antacid (calcium carbonate) orally to complex fluoride ions.

- B. Symptomatic hypocalcemia, hyperkalemia.** Give 10% calcium gluconate, 10–20 mL (children, 0.2–0.3 mL/kg), or 10% calcium chloride, 5–10 mL (children, 0.1–0.2 mL/kg), slowly IV. Repeat as needed every 5–10 minutes.
- C. Calcium antagonist poisoning.** Start with doses as described above. *High-dose calcium* therapy has been reported effective in some cases of severe calcium channel blocker overdose. As much as 12 g of calcium chloride has been given over 2 hours. Administer calcium as multiple boluses (eg, 1 g every 10–20 minutes) or as a continuous infusion (eg, 20–50 mg/kg/h).
- D. Dermal hydrofluoric acid exposure.** For any exposure involving the hand or fingers, obtain immediate consultation from an experienced hand surgeon or medical toxicologist. Regardless of the specific therapy chosen, systemic narcotic analgesics should be strongly considered as adjunctive therapy.
- 1. Topical.** Calcium concentrations for topical therapy have ranged from 2.5 to 33%; the optimal concentration has not been determined. Most commonly, a 2.5% gel is prepared by combining 1 g of calcium gluconate per 40 g (approximately 40 mL) of water-soluble base material (Surgilube, K-Y Jelly). A 32.5% gel can be made by compounding a slurry of ten 650-mg calcium carbonate tablets in 20 mL of water-soluble lubricant. For exposures involving the hand or fingers, place the gel into a large surgical latex glove to serve as an occlusive dressing to maximize skin contact.
 - For **subcutaneous** injection (when topical treatment fails to relieve pain), inject 5–10% calcium gluconate (**not** chloride) SC (0.5–1 mL/cm² of affected skin) using a 27-gauge or smaller needle. This can be repeated two to three times at 1- to 2-hour intervals if pain is not relieved. No more than 0.5 mL should be injected into each digit.
- 3. Bier block technique:**
- Establish distal IV access in the affected extremity (eg, dorsum of the hand).
 - Exsanguinate the extremity by elevation for 5 minutes. Alternatively, an Esmarch bandage may be utilized by wrapping from the distal to proximal extremity.
 - Inflate a BP cuff to just above systolic blood pressure. The arm can now be lowered or bandage removed.
 - With the cuff kept inflated, infuse 25–50 mL of a 2% calcium gluconate solution (10 mL of 10% calcium gluconate diluted with 40 mL of D5W) into the empty veins.
 - After 20–25 minutes, slowly release the cuff over 3–5 minutes.
 - Repeat if pain persists or use the intra-arterial infusion.
- 4. For intra-arterial** administration, dilute 10 mL of 10% calcium gluconate with 50 mL of D5W and infuse over 4 hours either through the brachial or radial artery catheter. The patient should be monitored closely over the next 4–6 hours and if pain recurs a second infusion should be given. Some authors have reported 48–72 hours of continuous infusion.
- E. Other sites of hydrofluoric acid exposure**
- 1. Nebulized** 2.5% calcium gluconate has been reported for cases of inhalational HF exposure. Inhalational exposure should be considered with dermal exposures of >5% total body surface area.
 - 2. Ocular** administration of 1% calcium gluconate solutions every 4–6 hours has been utilized for 24–48 hours but is of unproved efficacy over irrigation with saline or water. Higher concentrations of calcium gluconate may worsen corrosive injury to ocular structures. Ophthalmology consultation should be obtained.

VII. Formulations

- A. Oral.** Calcium carbonate; suspension, tablets, or chewable tablets; 300–800 mg.

- B. **Parenteral.** Calcium gluconate (10%), 10 mL (1 g contains 4.5 mEq calcium); calcium chloride (10%), 10 mL (1 g contains 13.6 mEq).
- C. **Topical.** No commercial formulation is approved currently in the United States.
- D. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 5–10 vials (1 g each) of 10% calcium gluconate.

► L-CARNITINE

Christine A. Haller, MD

I. Pharmacology

- A. Levocarnitine (L-carnitine) is an endogenous carboxylic acid involved in transport of long-chain fatty acids into cellular mitochondria for energy metabolism (Krebs cycle). L-carnitine is ubiquitous in diets rich in meats and dairy products, and is also synthesized in the body from the amino acids lysine and methionine. Although dietary deficiencies are rare, hypocarnitinemia can result from certain medical conditions and inborn errors of metabolism, and in patients receiving multiple anticonvulsant medications. It is hypothesized that valproic acid (VPA, see p 362) induces carnitine deficiency, thereby disrupting mitochondrial function and resulting in ammonia accumulation. Carnitine-deficient states may result in production of hepatotoxic VPA metabolites via microsomal oxidation. L-carnitine supplementation has been shown to be beneficial in both the prevention and treatment of hyperammonemia associated with VPA therapy, and carnitine may improve outcome in cases of valproic acid-induced hepatotoxicity and coma.
- B. L-carnitine is also sold as a dietary supplement with a wide range of unproven claims ranging from improved sperm motility to prevention of Alzheimer's disease. It is postulated that carnitine supplementation enhances fat utilization during exercise, thereby improving endurance and promoting weight loss. However, published studies have failed to show that supraphysiological doses of L-carnitine have any benefit in well-nourished individuals. Because the FDA does not regulate dietary supplements, the safety of L-carnitine supplements cannot be guaranteed (see Herbal Products, p 215).

II. Indications

- A. Hyperammonemia, encephalopathy, or hepatotoxicity related to valproic acid therapy.
- B. Low plasma free carnitine concentrations (reference range 19–60 $\mu\text{mol/L}$) or total carnitine (reference range 30–73 $\mu\text{mol/L}$) in patients taking valproic acid.
- C. Acute valproic acid overdose (see p 362) or supratherapeutic plasma VPA concentrations.
- D. Primary or secondary carnitine deficiency.
- E. Infants and children < 2 years of age receiving VPA as part of a multi-anticonvulsant drug regimen.

III. Contraindications. None known.

IV. Adverse effects

- A. Dose-related nausea, vomiting, diarrhea, and fishy body odor.
- B. Seizures have been reported in patients receiving oral and IV L-carnitine.
- C. **Use in Pregnancy.** Category B (see p 405). No adequate studies have been conducted in pregnant women. It is not known if this drug is secreted in human breast milk.

V. Drug or laboratory interactions. None known.

VI. Dosage and method of administration

- A. **Severe valproate-induced hepatotoxicity, hyperammonemia, coma, or acute valproic acid overdose.** Early intervention with IV (rather than oral)

L-carnitine is associated with better outcomes. Administer L-carnitine intravenously in dose of 50 mg/kg/day by infusion or slow bolus injection over 2–3 minutes. A loading dose followed by an equivalent dose within 24 hours may be given to severely ill patients.

- B. Drug-induced carnitine deficiency and asymptomatic hyperammonemia.** Give orally 50–100 mg/kg/day in two to three divided doses, with a maximum of 3 g per day.

VII. Formulations

- A. Oral.** Carnitor tablets (330 mg) and oral solution (1 g/10 mL) in 118-mL multiple-use containers.
- B. Parenteral.** Carnitor injection single-dose (5 mL) vials containing 1 g L-carnitine per vial.
- C. The suggested minimum stocking level** to treat a severely ill 70-kg adult for the first 24 hours is 7 g (seven vials).

► CHARCOAL, ACTIVATED

Thomas E. Kearney, PharmD

- I. Pharmacology.** Activated charcoal, by virtue of its large surface area, adsorbs many drugs and toxins. Highly ionic salts (eg, iron, lithium, and cyanide) or small polar molecules (eg, alcohols) are poorly adsorbed. Repeated oral doses of activated charcoal can increase the rate of elimination of some drugs that have a small volume of distribution (V_d) and that undergo enterogastric or enterohepatic recirculation (eg, digitoxin) or diffuse into the gastrointestinal lumen from the intestinal circulation (eg, phenobarbital and theophylline). See also discussion in Section I, p 51. Co-administration with cathartics is of unproven benefit and is associated with risks (see Section IV).

II. Indications

- A.** Activated charcoal is used orally after an ingestion to limit drug or toxin absorption. Although traditionally given after the stomach has been emptied by ipecac-induced emesis or gastric lavage, it is now more common practice and studies support that it may be used alone for most ingestions. Use in the home after a childhood exposure is controversial.
- B.** Repeated doses of activated charcoal may be indicated to enhance elimination of some drugs if (1) more rapid elimination will benefit the patient (and the benefits outweigh the risks of repeated doses; see IV.C and V.C, below), and (2) more aggressive means of removal (eg, hemodialysis or hemoperfusion) are not immediately indicated or available (see p 57). However, it has not been proven to improve patient outcome in clinical studies.
- C.** Repeated doses of activated charcoal may be useful when the quantity of drug or toxin ingested is greater than one-tenth of the usual charcoal dose (eg, an aspirin ingestion of more than 6–10 g) or when surface contact with the drug is hindered (eg, pharmacobezoars and wrapped or packaged drugs).

III. Contraindications

- A.** Gastrointestinal ileus or obstruction may prevent the administration of more than one or two doses.
- B.** Acid or alkali ingestions, unless other drugs have also been ingested (charcoal makes endoscopic evaluation more difficult).
- C.** Use of charcoal-sorbitol mixtures should be avoided in children (risk of hypernatremia and dehydration).
- D.** Obtunded patients at risk for aspiration of charcoal (need intact or protected airway).

IV. Adverse effects

- A.** Constipation (may be prevented by co-administration of a cathartic).

- B. Distention of the stomach, emesis (in particular if mixed with sorbitol) with potential risk of aspiration.
 - C. Diarrhea, dehydration, hypermagnesemia, and hypernatremia resulting from co-administered cathartics, especially with repeated doses of charcoal and cathartics, or even after a single large dose of a premixed, sorbitol-containing charcoal product.
 - D. Intestinal bezoar with obstruction (in particular with multidoses given to patients with impaired bowel motility).
 - E. **Use in pregnancy.** Activated charcoal is not systemically absorbed. Diarrhea resulting in shock or hypernatremia in the mother could conceivably adversely affect the fetus.
- V. **Drug or laboratory interactions**
- A. Activated charcoal may reduce, prevent, or delay the absorption of orally administered antidotes or other drugs (eg, acetylcysteine).
 - B. The adsorptive capacity of activated charcoal may be diminished by the concurrent ingestion of ice cream, milk, or sugar syrup; the clinical significance is unknown but is probably minor.
 - C. Repeated doses of charcoal may enhance the elimination of some necessary therapeutic drugs (eg, anticonvulsants).
- VI. **Dosage and method of administration**
- A. **Initial dose.** Activated charcoal, 1 g/kg (adult dose 50–100 g; child < 5 years, 10–25 g) orally or via gastric tube, is administered, or if the quantity of toxin ingested is known, 10 times the amount of ingested toxin by weight is given. For massive overdoses (eg, 60–100 g aspirin), this may need to be given in divided doses over 1–2 days.
 - B. **Repeat-dose charcoal.** Activated charcoal, 15–30 g (0.25–0.5 g/kg) every 2–4 hours or hourly (adults, average rate of 12.5 g/h; children, rate of 0.2 g/kg/h) is given orally or by gastric tube. (The optimal regimen and dose are unknown, but more frequent dosing to include continuous gastric infusion may be advantageous.) May administer a small dose of cathartic with every second or third charcoal dose (benefit is unproven). Do **not** use cathartic with every activated charcoal dose. Endpoints for repeat-dose charcoal therapy include clinical improvement and declining serum drug level; the usual empiric duration is 24–48 hours.
 - C. For patients with nausea or vomiting, administer antiemetics (metoclopramide, p 467, or ondansetron, p 481) and consider giving the charcoal by gastric tube.
- VII. **Formulations**
- A. There are a variety of formulations and a large number of brands of activated charcoal. It is available as a powder, pellets, a liquid aqueous suspension (preferable), and a liquid suspension in sorbitol or propylene glycol.
 - B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is three bottles containing 50 g of activated charcoal each. Preferred stock is the plain aqueous suspension.

► CIMETIDINE AND OTHER H₂ BLOCKERS

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Cimetidine, ranitidine, famotidine, and nizatidine are selective competitive inhibitors of histamine on H₂ receptors. These receptors modulate smooth muscle, vascular tone, and gastric secretions and may be involved in clinical effects associated with anaphylactic and anaphylactoid reactions, as well as ingestion of histamine or histamine-like substances (eg, scombroid fish poisoning). Cimetidine, as an inhibitor of cytochrome P-450 enzymes, has been proposed or studied in animals as an agent to block the production of toxic intermediate metabolites (eg, acetaminophen, carbon tetrachloride, halothane,

Amanita mushroom poisoning), but this has not been shown to be beneficial for human poisonings or toxicity.

II. Indications.

- A. Adjunctive with H_1 blockers such as diphenhydramine (see p 436) in the management and prophylactic treatment of anaphylactic and anaphylactoid reactions (see Antivenoms, pp 407–410).
- B. Adjunctive with H_1 blockers such as diphenhydramine (see p 436) in the management of scombroid fish poisoning (p 205).
- C. **Ranitidine** has been used to reduce vomiting associated with theophylline poisoning. Because cimetidine may interfere with hepatic elimination of theophylline, it should not be used.

III. Contraindications.

Known hypersensitivity to H_2 blockers.

IV. Adverse effects

- A. Headache, drowsiness, fatigue, and dizziness have been reported, but are usually mild.
- B. Confusion, agitation, hallucinations, and even seizures have been reported with cimetidine use in the elderly, severely ill, and patients with renal failure. A case was reported of a dystonic reaction after IV cimetidine administration.
- C. A reversible, dose-dependent rise in serum alanine aminotransferase (ALT) activity has been reported with nizatidine, a related agent. Hepatitis has also occurred with ranitidine.
- D. Cardiac dysrhythmias (bradycardia, tachycardia) and hypotension have been associated with rapid IV bolus of cimetidine and ranitidine (rare).
- E. Severe delayed hypersensitivity after high oral doses of cimetidine (case report).
- F. Preparations containing the preservative benzyl alcohol have been associated with “gasping syndrome” in premature infants.

V. Drug or laboratory interactions

- A. Cimetidine, and to a lesser extent ranitidine, reduces hepatic clearance and prolongs the elimination half-life of several drugs as a result of inhibition of cytochrome P-450 activity and reduction of hepatic blood flow. Examples of drugs affected include phenytoin, theophylline, phenobarbital, cyclosporine, morphine, lidocaine, calcium channel blockers, tricyclic antidepressants, and warfarin.
- B. Cimetidine, ranitidine, and nizatidine inhibit gastric mucosal alcohol dehydrogenase and therefore increase the systemic absorption of ethyl alcohol.
- C. Increased gastric pH may inhibit the absorption of some pH-dependent drugs such as ketoconazole, ferrous salts, and tetracyclines.

VI. Dosage and method of administration.

In general, there are no clinically proven advantages of any one of the H_2 blockers, although cimetidine is more likely to be associated with drug-drug interactions. The lowest-strength dosage forms are available OTC and several oral dosage form options (chewable tablets, oral solutions) may enhance palatability. See Table III–3 for oral and parenteral doses.

VII. Formulations

A. Cimetidine (Tagamet, others)

1. **Oral.** 100-, 200-, 300-, 400-, and 800-mg tablets; 300-mg/5 mL oral solution.
2. **Parenteral.** 150 mg/mL in 2- and 8-mL vials; premixed 300 mg in 50 mL saline.

B. Famotidine (Pepcid, Pepcid AC, Pepcid RPD)

1. **Oral.** 10-, 20-, and 40-mg tablets; 10-mg chewable tablets; 20- and 40-mg disintegrating tablets; 40-mg/5 mL oral suspension.
2. **Parenteral.** 10 mg/mL in 2- and 4-mL vials; premixed 20 mg in 50 mL saline.

C. Ranitidine (Zantac, others)

1. **Oral.** 75-, 150-, and 300-mg tablets and capsules; 15 mg/mL in 10 mL syrup; and 150-mg effervescent granules and tablets.

TABLE III-3. CIMETIDINE, FAMOTIDINE, NIZATIDINE, AND RANITIDINE

Drug	Route	Dose ^a
Cimetidine	PO	300 mg every 6–8 h or 400 mg every 12 h (maximum 2400 mg/day). Children: 10 mg/kg single dose; 20–40 mg/kg/day.
	IV, IM	300 mg IV or IM every 6–8 h. For IV administration, dilute in normal saline to a total volume of 20 mL and give over 2 min or longer. Children: 10 mg/kg.
Famotidine	PO	20–40 mg once or twice daily (as much as 160 mg every 6 h has been used).
	IV	20 mg IV every 12 h (dilute in normal saline to a total volume of 5–10 mL).
Ranitidine	PO	150 mg twice daily (up to 6 g/day has been used).
	IV, IM	50 mg IV or IM every 6–8 h. For IV use, dilute in normal saline to a total volume of 20 mL, and inject over 5 min or longer.
Nizatidine	PO	150 mg once to twice daily (or 300 mg once daily).

^aNote: May need to reduce dose in patients with renal dysfunction.

2. Parenteral. 0.5 mg/mL in 100-mL container; 25 mg/mL in 2-, 10-, and 40-mL vials and 2-mL syringe.

D. Nizatidine (Axid)

1. Oral. 75-mg tablets, and 150- and 300-mg capsules.

2. Parenteral. Not available in this dosage form.

E. The **suggested minimum stocking levels** to treat a 70-kg adult for the first 24 hours (all are parenteral dose form) are the following:

1. Cimetidine. 1200 mg (8-mL vial).

2. Famotidine. 40 mg (4-mL multidose vial).

3. Ranitidine. 250 mg (10-mL vial).

► CYANIDE ANTIDOTE PACKAGE

See Nitrite (p 476) and Thiosulfate (p 505).

► CYPROHEPTADINE

F. Lee Cantrell, PharmD

I. Pharmacology. Cyproheptadine is a first-generation, histamine-1 blocker with nonspecific serotonin (5-HT) antagonism. The administration of cyproheptadine to patients with serotonin syndrome appears to antagonize excessive stimulation of 5-HT_{1A} and 5-HT₂ receptors, resulting in improvements in clinical symptoms (based on anecdotal case reports).

II. Indications. **Cyproheptadine** may be beneficial in alleviating mild-moderate symptoms in cases of suspected serotonin syndrome (see p 22).

III. Contraindications

A. Known hypersensitivity to cyproheptadine.

B. Angle-closure glaucoma.

- C. Stenosing peptic ulcer.
- D. Symptomatic prostatic hypertrophy.
- E. Bladder neck obstruction.
- F. Pyloroduodenal obstruction.

IV. Adverse effects

- A. Transient mydriasis and urinary retention may result due to anticholinergic properties.
- B. **Use in pregnancy.** FDA category B (see p 405). Not likely to cause harm with short-term therapy.

V. Drug or laboratory interactions. Additive anticholinergic effects when given with other antimuscarinic drugs.

VI. Dosage and method of administration (adults and children)

- A. **Oral.** The initial dose is 4–8 mg orally, and can be repeated every 1–4 hours as needed until symptoms resolve or a maximum daily dose of 32 mg is reached (children: 0.25 mg/kg/day divided every 6 hours with a maximum of 12 mg/day).

VII. Formulations

- A. **Oral.** Cyproheptadine hydrochloride (Periactin, others), 4-mg tablets, 2-mg/5 mL syrup.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is one bottle (4 mg, 100 tablets).

► DANTROLENE

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Dantrolene relaxes skeletal muscle by inhibiting the release of calcium from the sarcoplasmic reticulum, thereby reducing actin-myosin contractile activity. Dantrolene can help control hyperthermia that results from excessive muscle hyperactivity, particularly when hyperthermia is caused by a defect within the muscle cell (eg, malignant hyperthermia). Dantrolene is not a substitute for other temperature-controlling measures (eg, sponging and fanning).

II. Indications

- A. The primary indication for dantrolene is malignant hyperthermia (see p 22).
- B. Dantrolene may be useful in treating hyperthermia and rhabdomyolysis caused by drug-induced muscular hyperactivity not controlled by usual cooling measures or neuromuscular paralysis.
- C. Dantrolene is not likely to be effective for hyperthermia caused by conditions other than muscular hyperactivity, such as increased metabolic rate (eg, salicylate or dinitrophenol poisoning), neuroleptic malignant syndrome (NMS), impaired heat dissipation (eg, anticholinergic syndrome), or environmental exposure (heat stroke). However, there is anecdotal evidence (case reports or case-control studies) of benefit for the management of NMS, MAO inhibitor (phenelzine poisoning)–induced hyperthermia, muscle rigidity from baclofen withdrawal, hypertonicity from carbon monoxide poisoning, tetanus, and black widow spider envenomation.

- III. **Contraindications.** No absolute contraindications exist. Patients with muscular weakness or respiratory impairment must be observed closely for possible respiratory arrest.

IV. Adverse effects

- A. Muscle weakness, which may aggravate respiratory depression.
- B. Drowsiness, fatigue, dizziness, photosensitivity, and diarrhea.
- C. **Black Box warning.** Potential for fatal hepatotoxicity (hypersensitivity hepatitis) reported after chronic therapy. May also be dose related (more common with 800 mg/day). Transaminases are elevated in about 10% of patients treated with dantrolene.

- D. IV administration associated with pulmonary edema (mannitol may contribute), phlebitis, and urticaria (avoid extravasation).
- E. **Use in pregnancy.** FDA category C (indeterminate). This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).
- V. **Drug or laboratory interactions**
 - A. Dantrolene may have additive central nervous system–depressant effects with sedative and hypnotic drugs.
 - B. Dantrolene and verapamil co-administration associated with hyperkalemia (case report).
 - C. Each 20-mg vial of Dantrium contains 3 g of mannitol; this should be taken into consideration as it may have additive effects with any mannitol given to treat rhabdomyolysis. Only use sterile water (without bacteriostatic agent) to reconstitute. Incompatible with D5W and NS.
- VI. **Dosage and method of administration (adults and children)**
 - A. **Parenteral.** Give 1–2 mg/kg rapidly IV; this may be repeated as needed every 5–10 minutes, to a maximum total dose of 10 mg/kg. Satisfactory response is usually achieved with 2–5 mg/kg.
 - B. **Oral.** To prevent recurrence of hyperthermia, administer 1–2 mg/kg intravenously or orally (up to 100 mg maximum) four times a day for 2–3 days. Daily dose not to exceed 400 mg.
- VII. **Formulations**
 - A. **Parenteral.** Dantrolene sodium (Dantrium), 20 mg of lyophilized powder for reconstitution (after reconstitution, protect from light and use within 6 hours to ensure maximal activity). Each 20-mg vial contains 3 g of mannitol (see adverse effects and interactions).
 - B. **Oral.** Dantrolene sodium (Dantrium) in 25-, 50-, and 100-mg capsules.
 - C. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is thirty-five 20-mg vials.

► DEFEROXAMINE

Anthony S. Manoguerro, PharmD

- I. **Pharmacology.** Deferoxamine is a specific chelating agent for iron. It binds free iron and, to some extent, loosely bound iron (eg, from ferritin or hemosiderin). Iron bound to hemoglobin, transferrin, cytochrome enzymes, and all other sites is unaffected. The red iron-deferoxamine (ferrioxamine) complex is water soluble and is excreted renally, where it imparts an orange-pink, or “vin rosé” color to the urine. One hundred milligrams of deferoxamine is capable of binding 8.5 mg of elemental iron in vitro. The basic science literature supports the use of the drug, but clinical evidence of efficacy and safety is lacking.
- II. **Indications**
 - A. Deferoxamine is used to treat iron intoxication when the serum iron is greater than 450–500 mcg/dL or when clinical signs of significant iron intoxication exist (eg, shock, acidosis, severe gastroenteritis, or numerous radiopaque tablets visible in the gastrointestinal tract by x-ray).
 - B. Deferoxamine is sometimes used as a “test dose” to determine the presence of free iron by observing for the characteristic vin rosé color in the urine; however, a change in urine color is not a reliable indicator.
- III. **Contraindications.** No absolute contraindications to deferoxamine use exist in patients with serious iron poisoning. The drug should be used with caution in patients with known sensitivity to deferoxamine.
- IV. **Adverse effects**
 - A. Hypotension or an anaphylactoid-type reaction may occur from very rapid intravenous bolus administration; this may be avoided by limiting the rate of administration to 15 mg/kg/h.

- B. Local pain, induration, and sterile abscess formation may occur at intramuscular injection sites. Large intramuscular injections may also cause hypotension.
 - C. The ferrioxamine complex may itself cause hypotension and may accumulate in patients with renal impairment; hemodialysis may be necessary to remove the ferrioxamine complex.
 - D. Deferoxamine, as a siderophore, promotes the growth of certain bacteria such as *Yersinia enterocolitica* and may predispose patients to *Yersinia* sepsis.
 - E. Infusions exceeding 24 hours have been associated with pulmonary complications (acute respiratory distress syndrome [ARDS]).
 - F. **Use in pregnancy.** FDA category C (indeterminate). Although deferoxamine is a teratogen in animals, it has relatively poor placental transfer, and there is no evidence that short-term treatment is harmful in human pregnancy (see p 405). More importantly, failure to treat a serious acute iron intoxication may result in maternal and fetal morbidity or death.
- V. **Drug or laboratory interactions.** Deferoxamine may interfere with determinations of serum iron (falsely low) and total iron-binding capacity (falsely high). It may chelate and remove aluminum from the body.
- VI. **Dosage and method of administration**
- A. The intravenous route is preferred in all cases. In children or adults, give deferoxamine at an infusion rate generally not to exceed 15 mg/kg/h (although rates up to 40–50 mg/kg/h have been given in patients with massive iron intoxication). The maximum cumulative daily dose should generally not exceed 6 g (doses up to 16 g have been tolerated). The endpoints of therapy include loss of vin rosé-colored urine, a serum iron level less than 350 mcg/dL, and resolution of clinical signs of intoxication.
 - B. Oral complexation is **not** recommended.
 - C. “Test dose” intramuscular injection is **not** recommended. If the patient is symptomatic, use the intravenous route. If the patient is not symptomatic but serious toxicity is expected to occur, intravenous access is essential (eg, for fluid boluses), and intravenous dosing provides more reliable administration.
- VII. **Formulations**
- A. **Parenteral.** Deferoxamine mesylate (Desferal), vials containing 500 mg of lyophilized powder.
 - B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 12 vials.

► DIAZOXIDE

Thomas E. Kearney, PharmD

I. Pharmacology

- A. Diazoxide, a nondiuretic thiazide, is a direct arterial vasodilator formerly used to treat severe hypertension. Heart rate and cardiac output increase owing to a reflex response to decreased peripheral vascular resistance. The duration of the hypotensive effect ranges from 3 to 12 hours, although the elimination half-life is 20–40 hours.
- B. Diazoxide has been used in the treatment of oral hypoglycemic overdose because it increases serum glucose by inhibiting insulin secretion, diminishing peripheral glucose utilization, and enhancing hepatic glucose release. However, octreotide (see p 480) has become the preferred agent due to its safety and efficacy.

II. Indications

- A. Management of an acute hypertensive crisis, although other antihypertensive agents are preferred (see Phentolamine, p 487; Nitroprusside, p 477; and Labetalol, p 459).

- B. Oral hypoglycemic overdose, when serum glucose concentrations cannot be adequately maintained by intravenous 5% dextrose infusions and the preferred agent, octreotide, is unavailable or intolerable to the patient (known hypersensitivity).

III. Contraindications

- A. Hypertension associated with aortic stenosis, aortic coarctation, hypertrophic cardiomyopathy, or arteriovenous shunt.
- B. Known hypersensitivity to thiazides or other sulfonamide derivatives.

IV. Adverse effects

- A. Hypotension or excessive blood pressure reduction must be avoided in patients with compromised cerebral or cardiac circulation.
- B. Fluid retention from prolonged therapy may compromise patients with congestive heart failure.
- C. Hyperglycemia may occur, particularly in patients with diabetes or hepatic dysfunction.
- D. **Use in pregnancy.** FDA category C (indeterminate). This drug has caused skeletal, cardiac, and pancreatic abnormalities in animals, but no adequate human data exist. Use of this drug near term may cause hyperbilirubinemia and altered carbohydrate metabolism in the fetus or neonate, and intravenous administration during labor may cause cessation of uterine contractions. These cautions, however, do not necessarily preclude acute, short-term use of the drug for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A. The hypotensive effect is potentiated by concomitant therapy with diuretics or beta-adrenergic blockers.
- B. Diazoxide displaces warfarin from protein-binding sites and may transiently potentiate its anticoagulant effects.
- C. Diazoxide can increase phenytoin metabolism.

VI. Dosage and method of administration (adults and children)

A. For oral hypoglycemic-induced hypoglycemia:

1. Give a 0.1–2 mg/kg/h infusion; initiate at a lower infusion rate and titrate up as needed. Hypotension is minimized by keeping the patient supine and increasing the infusion rate slowly. Duration of therapy has ranged from 22 to 60 hours.
2. An oral dosing regimen of 3–8 mg/kg/day divided into two to three doses is recommended for children and adults. If refractory, may require higher doses of up to 10 to 15 mg/kg/day (200 mg every 4 hours has been used).

- B. **For hypertensive crisis,** give 1–3 mg/kg IV (150 mg maximum) every 5–15 minutes as needed. **Note:** The use of a 300-mg rapid bolus is no longer recommended.

VII. Formulations

- A. **Parenteral.** Diazoxide (Hyperstat), 15 mg/mL in 20-mL ampules.

- B. **Oral.** Diazoxide (Proglycem), 50-mg capsules, or 50-mg/mL oral suspension.

- C. The **suggested minimum stocking levels** to treat a 70-kg adult for the first 24 hours: parenteral, two vials (20 mL each); oral, one bottle (100 tablets) or 30 mL of suspension.

► DIGOXIN-SPECIFIC ANTIBODIES

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Digoxin-specific antibodies are produced in immunized sheep and have a high binding affinity for digoxin and (to a lesser extent) digitoxin and other cardiac glycosides. The Fab fragments used to treat poisoning are derived

by cleaving the whole antibodies. The Fab fragment binds free digoxin. Once the digoxin-Fab complex is formed, the digoxin molecule is no longer pharmacologically active. The complex enters the circulation, is renally eliminated and cleared by the reticuloendothelial system, and has a half-life of 14–20 hours (may increase 10-fold with renal impairment). Reversal of signs of digitalis intoxication usually occurs within 30–60 minutes of administration (average initial response, 19 minutes), with complete reversal varying up to 24 hours (average 88 minutes). There are two commercially available products, Digibind and DigiFab, that should be considered therapeutic equivalents. The decision to use either product may be based on availability and cost.

II. Indications. Digoxin-specific antibodies are used for life-threatening arrhythmias or hyperkalemia (≥ 5 mEq/L) caused by cardiac glycoside intoxication (see p 155).

III. Contraindications. No contraindications are known. Caution is warranted in patients with known sensitivity to ovine (sheep) products; a skin test for hypersensitivity may be performed in such patients, using diluted reconstituted drug. There are no reports of hypersensitivity reactions in patients who have received the drug more than once (although a theoretical risk). Product may contain traces of papain; therefore, caution is advised in patients with allergies to papain, chymopapain, papaya extracts, and the pineapple enzyme bromelain.

IV. Adverse effects

- A.** Monitor the patient for potential hypersensitivity reactions and serum sickness. A dose- and rate-related (anaphylactoid) reaction may occur with rapid IV administration.
- B.** In patients with renal insufficiency and impaired clearance of the digitalis-Fab complex, a delayed rebound of free serum digoxin levels may occur for up to 130 hours.
- C.** Removal of the inotropic effect of digitalis may exacerbate preexisting heart failure.
- D.** With removal of digitalis effect, patients with preexisting atrial fibrillation may develop accelerated ventricular response.
- E.** Removal of the digitalis effect may reactivate sodium-potassium ATPase and shift potassium into cells, causing a drop in the serum potassium level.
- F. Use in pregnancy.** FDA category C (indeterminate). This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A.** Digoxin-specific Fab fragments will bind other cardiac glycosides including digitoxin, ouabain, oleander glycosides, and possibly glycosides in lily of the Nile, strophanthus, squill, and toad venom (*Bufo* species cardenolides).
- B.** The digoxin-Fab complex cross-reacts with the antibody commonly utilized in quantitative immunoassay techniques. This results in falsely high serum concentrations of digoxin owing to measurement of the inactive Fab complex (total serum digoxin levels may increase 10- to 21-fold). However, some assays and procedures may measure free digoxin levels, which may be useful for patients with renal impairment (to monitor a rebound in free serum digoxin levels after administration of Fab fragments).

VI. Dosage and method of administration. Each vial of either digoxin-immune Fab product binds 0.5 mg of digoxin.

- A.** Estimation of the dose of Fab is based on the body burden of digitalis. This may be calculated if the approximate amount ingested is known (Table III–4) or if the steady-state (postdistributional) serum drug concentration is known (Table III–5). (The steady-state serum drug concentration should be determined at least 12–16 hours after the last dose.) **Note:** The calculation of digoxin body burden is based on an estimated volume of distribution for digoxin of approximately 5–6 L/kg; however, other estimates for the V_d range as high as 8 L/kg. If the patient fails to respond to the initial treatment, the dose may need to increase by an additional 50%.

TABLE III-4. APPROXIMATE DIGOXIN-FAB DOSE IF AMOUNT INGESTED IS KNOWN

Tablets Ingested (0.125-mg size)	Tablets Ingested (0.25-mg size)	Approximate Dose Absorbed (mg)	Recommended Dose (no. of vials)
5	2.5	0.5	1
10	5	1	2
20	10	2	4
50	25	5	10
100	50	10	20

TABLE III-5. APPROXIMATE DIGOXIN-FAB DOSE BASED ON SERUM CONCENTRATION AT STEADY STATE (AFTER EQUILIBRATION)

$$\text{Digoxin: } ^a \text{ Number of digoxin-Fab vials} = \frac{\text{serum digoxin (ng / mL)} \times \text{body weight (kg)}}{100}$$

$$\text{Digitoxin: Number of digoxin-Fab vials} = \frac{\text{serum digitoxin (ng / mL)} \times \text{body weight (kg)}}{1000}$$

^aThis calculation provides a quick estimate of the number of vials needed, but could underestimate the actual need, because of variations in the volume of distribution (5–7 L/kg). Be prepared to increase dose by 50% if clinical response to initial dose is not satisfactory.

- B. If the amount ingested or the postdistributional level is not known and the patient has life-threatening dysrhythmias, dosing may have to be empiric. Manufacturer recommends 20 (10 for children) and 6 vials be given empirically for acute and chronic overdoses, respectively. However, average dose requirements are 10 and 5 vials for acute and chronic digoxin intoxication, respectively.
- C. Theoretically, Fab may be used to neutralize a *portion* of the digoxin body burden to reverse toxicity but maintain therapeutic benefits. The Fab dose can be estimated by subtracting the desired digoxin level from the measured postdistributional level before completing the calculation. Alternately, if the patient is hemodynamically stable, the drug can be given empirically, a vial at a time, titrating to clinical effect. However, partial dosing has been associated with recurrences of symptoms in some digoxin-poisoned patients.
- D. Reconstitute the drug according to package instructions, and administer intravenously over 30 minutes using a 0.22-micron membrane filter. It may be given as a rapid bolus for immediately life-threatening arrhythmias.

VII. Formulations

- A. **Parenteral.** Digibind, 38 mg of lyophilized digoxin-specific Fab fragments per vial. DigiFab, 40 mg of lyophilized digoxin-specific Fab fragments per vial.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 20 vials of either product.

► DIPHENHYDRAMINE

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Diphenhydramine is an antihistamine with anticholinergic, anti-tussive, antiemetic, and local anesthetic properties. The antihistaminic property

affords relief from itching and minor irritation caused by plant-induced dermatitis and insect bites and, when used as pretreatment, provides partial protection against anaphylaxis caused by animal serum-derived antivenoms or antitoxins. Drug-induced extrapyramidal symptoms respond to the anticholinergic effect of diphenhydramine. The effects of diphenhydramine are maximal at 1 hour after intravenous injection, and they last up to 7 hours. The drug is eliminated by hepatic metabolism, with a serum half-life of 3–7 hours.

II. Indications

- A. Relief of symptoms caused by excessive histamine effect (eg, ingestion of scombroid-contaminated fish or niacin and rapid intravenous administration of acetylcysteine). Diphenhydramine may be combined with cimetidine or another H_2 histamine receptor blocker (see p 428).
- B. Pretreatment before administration of animal serum-derived antivenoms or antitoxins, especially in patients with a history of hypersensitivity or with a positive skin test. Diphenhydramine can be combined with cimetidine or another H_2 histamine receptor blocker.
- C. Neuroleptic drug-induced extrapyramidal symptoms and priapism (one case report).
- D. Pruritus caused by poison oak, poison ivy, or minor insect bites.

III. Contraindications

- A. Angle-closure glaucoma.
- B. Prostatic hypertrophy with obstructive uropathy.
- C. Concurrent therapy with monoamine oxidase inhibitors.

IV. Adverse effects

- A. Sedation, drowsiness, and ataxia may occur. Paradoxical excitation is possible in small children.
- B. Excessive doses may cause flushing, tachycardia, blurred vision, delirium, toxic psychosis, urinary retention, and respiratory depression.
- C. Some preparations may contain sulfite preservatives, which can cause allergic-type reactions in susceptible persons.
- D. It may exacerbate dyskinetic movement disorders due to increased dopamine (eg, amphetamine or cocaine intoxication) or decreased cholinergic effects in the CNS.
- E. **Use in pregnancy.** FDA category B (see p 405). Fetal harm is extremely unlikely.

V. Drug or laboratory interactions

- A. Additive sedative effect with opioids, ethanol, and other sedatives.
- B. Additive anticholinergic effect with other antimuscarinic drugs.

VI. Dosage and method of administration

- A. **Pruritus.** Give 25–50 mg PO every 6–8 hours (children, 5 mg/kg/day in divided doses); maximum adult daily dose, 300 mg. The drug may also be applied topically, although systemic absorption and toxicity have been reported, especially when used on large areas with blistered or broken skin.
- B. **Pretreatment before antivenom administration.** Give 50 mg (children, 0.5–1 mg/kg) IV; if possible, it should be given at least 15–20 minutes before antivenom use.
- C. **Drug-induced extrapyramidal symptoms.** Give 50 mg (children, 0.5–1 mg/kg) IV or IM; if there is no response within 30–60 minutes, repeat dose to a maximum 100 mg (adults). Provide oral maintenance therapy, 25–50 mg (children, 0.5–1 mg/kg) every 4–6 hours for 2–3 days to prevent recurrence.

VII. Formulations

- A. **Oral.** Diphenhydramine hydrochloride (Benadryl, others), 25- and 50-mg tablets and capsules; elixir and solution, 12.5 mg/5 mL.
- B. **Parenteral.** Diphenhydramine hydrochloride (Benadryl, others), 10- and 50-mg/mL solutions.
- C. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is five vials (10 mg/mL, 10 mL each).

► DOPAMINE

Neal L. Benowitz, MD

- I. **Pharmacology.** Dopamine is an endogenous catecholamine and the immediate metabolic precursor of norepinephrine. It stimulates alpha- and beta-adrenergic receptors directly and indirectly. In addition, it acts on specific dopaminergic receptors. Its relative activity at these various receptors is dose related. At low infusion rates (1–5 mcg/kg/min), dopamine stimulates beta-1 activity (increased heart rate and contractility) and increases renal and mesenteric blood flow through dopaminergic agonist activity. At high infusion rates (≥ 10 –20 mcg/kg/min), alpha-adrenergic stimulation predominates, resulting in increased peripheral vascular resistance. Dopamine is not effective orally. After IV administration, its onset of action occurs within 5 minutes, and the duration of effect is less than 10 minutes. The plasma half-life is about 2 minutes.
- II. **Indications**
 - A. Dopamine is used to increase blood pressure, cardiac output, and urine flow in patients with shock who have not responded to intravenous fluid challenge, correction of hypothermia, or reversal of acidosis.
 - B. Low-dose infusion is most effective for hypotension caused by venodilation or reduced cardiac contractility; high-dose dopamine is indicated for shock resulting from decreased peripheral arterial resistance.
- III. **Contraindications**
 - A. Uncorrected tachyarrhythmias or ventricular fibrillation and uncorrected hypovolemia.
 - B. High-dose infusion is relatively contraindicated in the presence of peripheral arterial occlusive disease with thrombosis or in patients with ergot poisoning (see p 189).
- IV. **Adverse effects**
 - A. Severe hypertension, which may result in intracranial hemorrhage, pulmonary edema, or myocardial necrosis.
 - B. Aggravation of tissue ischemia, resulting in gangrene (with high-dose infusion).
 - C. Ventricular arrhythmias, especially in patients intoxicated by halogenated or aromatic hydrocarbon solvents or anesthetics.
 - D. Tissue necrosis after extravasation (see VI.A, below, for treatment of extravasation).
 - E. Anaphylactoid reaction induced by sulfite preservatives in sensitive patients.
 - F. **Use in pregnancy.** FDA category C (indeterminate). There may be a dose-related effect on uterine blood flow. This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).
- V. **Drug or laboratory interactions**
 - A. Enhanced pressor response may occur in the presence of cocaine and cyclic antidepressants owing to inhibition of neuronal reuptake.
 - B. Enhanced pressor response may occur in patients taking monoamine oxidase inhibitors, owing to inhibition of neuronal metabolic degradation.
 - C. Chloral hydrate and halogenated hydrocarbon anesthetics may enhance the arrhythmogenic effect of dopamine, owing to sensitization of the myocardium to effects of catecholamines.
 - D. Alpha- and beta-blocking agents antagonize the adrenergic effects of dopamine; haloperidol and other dopamine antagonists may antagonize the dopaminergic effects.
 - E. There may be a reduced pressor response in patients with depleted neuronal stores of catecholamines (eg, chronic disulfiram or reserpine use).
- VI. **Dosage and method of administration (adults and children)**
 - A. **Avoid extravasation. Caution:** The intravenous infusion must be free flowing, and the infused vein should be observed frequently for signs of subcutaneous infiltration (pallor, coldness, or induration). If extravasation occurs, immediately infiltrate the affected area with phentolamine (see p 487), 5–10 mg

in 10–15 mL of normal saline (children, 0.1–0.2 mg/kg; maximum 10 mg total) via a fine (25- to 27-gauge) hypodermic needle; improvement is evidenced by hyperemia and return to normal temperature. Topical nitrates and infiltration of terbutaline have also been reported successful for treatment of extravasation involving other catecholamines.

- B. For **predominantly inotropic effects**, begin with 1 mcg/kg/min and increase infusion rate as needed to 5–10 mcg/kg/min.
- C. For **predominantly vasopressor effects**, infuse 10–20 mcg/kg/min and increase as needed. Doses above 50 mcg/kg/min may result in severe peripheral vasoconstriction and gangrene.

VII. Formulations.

- A. Dopamine hydrochloride (Intropin and others): as a concentrate for admixture to intravenous solutions (40-, 80-, and 160-mg/mL in 5-mL vials) or premixed parenteral product for injection (0.8-, 1.6-, and 3.2-mg/mL in 5% dextrose). All contain sodium bisulfite as a preservative.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is approximately 1800–2000 mg (two to three vials, 160 mg/mL, 5 mL each).

► DTPA

Michael A. Miller, MD

- I. **Pharmacology.** Diethylenetriaminepentaacetate (Zn-DTPA and Ca-DTPA) is a chelating agent that has been used for treatment of plutonium exposures as well as other elements such as americium and californium. DTPA is used in a calcium or zinc salt form and functions by forming a chelate with metal ions that can then be excreted in the urine. DTPA has a plasma half-life of 20–60 minutes and is distributed in the extracellular space. It has a small amount of protein binding and does not undergo significant metabolism or tissue accumulation.

- II. **Indications.** DTPA is indicated for internal contamination with plutonium and other transuranium ions such as americium.

III. Contraindications

- A. Known hypersensitivity to the agent.
- B. DTPA should not be used in uranium or neptunium exposures as it may increase bone deposition of these elements.
- C. Ca-DTPA should not be used in patients with renal failure, nephrotic syndrome, or bone marrow suppression.

IV. Adverse effects

- A. Nausea, vomiting, and diarrhea.
- B. Fever, chills and myalgias.
- C. Life-threatening side effects are distinctly uncommon with no serious toxicity in human subjects after 4500 administrations of Ca-DTPA and 1000 administrations of Zn-DTPA.
- D. **Use in pregnancy.** FDA category D (Ca-DTPA) and category C (Zn-DTPA); Zn-DTPA may be used in pregnancy, though fetal risks are not completely known (see p 405).

V. Drug or laboratory interactions

- A. There are no major known drug interactions.
- B. There does not appear to be a decrement of body trace elements associated with the use of DTPA.

VI. Dosage and method of administration

- A. Each exposure and patient may require a tailored dosing regimen.
- B. Upon known exposure, usual therapy would involve Ca- or Zn-DTPA to be given in a 1-g dosage as soon as possible. This may be given IV over 3–5

minutes in an undiluted form, or may be diluted in 100–250 cc of NS or LR. Administration time should not exceed 2 hours.

- C. Nebulization in a 1:1 dilution is safe and effective.
- D. IM dosing is not generally recommended due to significant pain with injection.
- E. Dosing is generally given daily for 5 days and then modified based upon estimation of radioactive body burden.

VII. Formulations

- A. **Parenteral or nebulization.** One gram in 5 cc of diluent.
- B. **Suggested minimum stocking level.** Not relevant—available only through REAC/TS (the US Radiation Emergency Assistance Center), which should be contacted for information on obtaining DTPA and proper dosing in the case of significant exposures ([865] 576-3131). Further information available on the Internet at www.orau.gov/reacts.

► EDTA, CALCIUM (CALCIUM DISODIUM EDTA, CALCIUM DISODIUM EDETATE, CALCIUM DISODIUM VERSENATE)

Michael J. Kosnett, MD, MPH

- I. **Pharmacology.** Calcium EDTA has been used as a chelating agent to enhance elimination of certain toxic metals, principally lead. The elimination of endogenous metals, including zinc, manganese, iron, and copper, may also occur to a lesser extent. The plasma half-life of the drug is 20–60 minutes, and 50% of the injected dose is excreted in the urine within 1 hour. Increased urinary excretion of lead begins within 1 hour of EDTA administration and is followed by a decrease in whole-blood lead concentration over the course of treatment. Calcium EDTA mobilizes lead from soft tissues and from a fraction of the larger lead stores present in bone. In persons with high body lead burdens, cessation of EDTA chelation is often followed by an upward rebound in blood lead levels as bone stores equilibrate with lower soft-tissue levels. **Note:** Calcium EDTA should **not** be confused with sodium EDTA (edetate disodium), which is occasionally used to treat life-threatening severe hypercalcemia.

II. Indications

- A. Calcium EDTA has been used to decrease blood lead concentrations and increase urinary lead excretion in individuals with symptomatic lead intoxication (see p 440) and in asymptomatic persons with high blood lead levels. Although clinical experience associates calcium EDTA chelation with relief of symptoms (particularly lead colic) and decreased mortality, controlled clinical trials demonstrating therapeutic efficacy are lacking, and treatment recommendations have been largely empiric.
- B. Calcium EDTA may have possible utility in poisoning by zinc, manganese, and certain heavy radioisotopes.

- III. **Contraindications.** Since calcium EDTA increases renal excretion of lead, anuria is a relative contraindication. Accumulation of EDTA increases the risk of nephropathy, especially in volume-depleted patients. In patients with moderate renal insufficiency, reduce the dose in relative proportion to the deficit in creatinine clearance. The use of EDTA in conjunction with hemodialysis or hemofiltration has been reported in patients with renal failure.

IV. Adverse effects

- A. Nephrotoxicity (eg, acute tubular necrosis, proteinuria, and hematuria) may be minimized by adequate hydration, establishment of adequate urine flow, avoidance of excessive doses, and limitation of continuous administration to 5 or fewer days. Laboratory assessment of renal function should be performed daily during treatment for severe intoxication and after the second and fifth days in other cases.

- B. In individuals with lead encephalopathy, rapid or high-volume infusions may exacerbate increased intracranial pressure. In such cases, it is preferable to use lower-volume, more concentrated solutions for intravenous infusions. Alternatively, intramuscular injection may be considered.
 - C. Local pain may occur at intramuscular injection sites. Lidocaine (1 mL of 1% lidocaine per mL of EDTA concentrate) may be added to intramuscular injections to decrease discomfort.
 - D. Inadvertent use of sodium EDTA (edetate disodium) may cause serious hypocalcemia.
 - E. Calcium EDTA may result in short-term zinc depletion, which has uncertain clinical significance.
 - F. **Use in pregnancy.** The safety of calcium EDTA in human pregnancy has not been established, although uncomplicated use late in pregnancy has been reported. Fetal malformations with high doses have been noted in animal studies, possibly as a consequence of zinc depletion. If severe lead poisoning necessitates use during pregnancy, maternal zinc supplementation should be considered.
- V. **Drug or laboratory interactions.** Intravenous infusions may be incompatible with 10% dextrose solutions, amphotericin, or hydralazine.
- VI. **Dosage and method of administration for lead poisoning (adults and children).** **Note:** Administration of EDTA should never be a substitute for removal from lead exposure. In adults, the federal OSHA lead standard requires removal from occupational lead exposure of any worker with a single blood lead concentration in excess of 60 mcg/dL or an average of three successive values in excess of 50 mcg/dL. (However, recent declines in background lead levels and concern over adverse health effects of lower-level exposure support removal at even lower levels). **Prophylactic chelation**, defined as the routine use of chelation to prevent elevated blood lead concentrations or to lower blood lead levels below the standard in asymptomatic workers, **is not permitted**. Consult the local or state health department or OSHA (see Table IV-3, p 525) for more detailed information.
- A. **Lead poisoning with encephalopathy, acute lead colic, or blood lead levels greater than 150 mcg/dL:**
- 1. **Adults:** 2–4 g (or 30–50 mg/kg) IV per 24 hours, as a continuous infusion (diluted to 2–4 mg/mL in normal saline or 5% dextrose). Courses of treatment should not exceed 5 days.
 - 2. **Children:** 1000–1500 mg/m² per 24 hours as a continuous IV infusion (diluted to 2–4 mg/mL in normal saline or 5% dextrose). Some clinicians advocate that treatment of patients with lead encephalopathy, particularly children, be initiated along with a single dose of BAL (dimercaprol; see p 413), followed 4 hours later by the concomitant administration of BAL and calcium EDTA. BAL is discontinued after 3 days; EDTA may be continued for up to 5 consecutive days.
- B. **Symptomatic lead poisoning without encephalopathy or colic.** Administer calcium EDTA at an adult dose of 2–4 g (or 30–50 mg/kg) IV per 24 hours, or at a pediatric dose of 1000–1500 mg/m²/day (approximately 20–30 mg/kg as a continuous IV infusion, diluted to 2–4 mg/mL) for 3–5 days.
- C. Although intravenous administration is preferable, the daily dose (see above) may be administered by deep intramuscular injection in two or three divided doses (every 8–12 hours).
- D. Because EDTA enhances urinary lead excretion, provide adequate fluids to maintain urine flow (optimally 1–2 mL/kg/h). However, avoid overhydration, which may aggravate cerebral edema.
- E. Treatment courses should be separated by a minimum of 2 days, and an interval of 2 or more weeks may be indicated to assess the extent of posttreatment rebound in blood lead levels. An additional course of calcium EDTA treatment may be considered based on posttreatment blood lead concentrations and the persistence or recurrence of symptoms.

- F. Consider changing to oral succimer (see p 501) or oral unithiol (p 506) after 3 to 5 days of calcium EDTA treatment, provided that encephalopathy or colic has resolved, the blood lead level has fallen to less than 100 mcg/dL, and the patient is able to absorb an oral formulation.
- G. Single-dose EDTA chelation lead mobilization tests have been advocated by some clinicians to evaluate body lead burden or to assess the need for a full course of treatment in patients with moderately elevated blood lead levels, but the value and necessity of these tests are controversial.
- H. Oral EDTA therapy is **not** recommended for prevention or treatment of lead poisoning, because it may *increase* the absorption of lead from the gastrointestinal tract.

VII. Formulations

- A. **Parenteral.** Calcium disodium edetate (Versenate), 200 mg/mL, 5-mL ampules. For intravenous infusion, dilute to 2–4 mg/mL in normal saline or 5% dextrose solution.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is three boxes (six ampules per box, 18 g).

► EPINEPHRINE

Neal L. Benowitz, MD

- I. **Pharmacology.** Epinephrine is an endogenous catecholamine with alpha- and beta-adrenergic agonist properties, used primarily in emergency situations to treat anaphylaxis or cardiac arrest. Beneficial effects include inhibition of histamine release from mast cells and basophils, bronchodilation, positive inotropic effects, and peripheral vasoconstriction. Epinephrine is not active after oral administration. Subcutaneous injection produces effects within 5–10 minutes, with peak effects at 20 minutes. Intravenous or inhalational administration produces much more rapid onset. Epinephrine is rapidly inactivated in the body, with an elimination half-life of 2 minutes.

II. Indications

- A. Anaphylaxis and anaphylactoid reactions.
- B. Epinephrine is occasionally used for hypotension resulting from overdose by beta blockers, calcium antagonists, and other cardiac-depressant drugs.

III. Contraindications

- A. Uncorrected tachyarrhythmias or ventricular fibrillation and uncorrected hypovolemia.
- B. Epinephrine is relatively contraindicated in patients with organic heart disease, peripheral arterial occlusive vascular disease with thrombosis, or ergot poisoning (see p 189).
- C. Narrow-angle glaucoma.

IV. Adverse effects

- A. Anxiety, restlessness, tremor, and headache.
- B. Severe hypertension, which may result in intracranial hemorrhage, pulmonary edema, or myocardial necrosis or infarction.
- C. Use with caution in patients intoxicated by halogenated or aromatic hydrocarbon solvents and anesthetics, because these may sensitize the myocardium to the arrhythmogenic effects of epinephrine.
- D. Tissue necrosis after extravasation or intra-arterial injection.
- E. Aggravation of tissue ischemia, resulting in gangrene.
- F. Anaphylactoid reaction, which may occur owing to the bisulfite preservative in patients with sulfite hypersensitivity.
- G. Hypokalemia, hypophosphatemia, hyperglycemia, and leukocytosis may occur owing to beta-adrenergic effects of epinephrine.
- H. **Use in pregnancy.** FDA category C (indeterminate). It is teratogenic in animals, crosses the placenta, can cause placental ischemia, and may suppress

uterine contractions, but these effects do not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A. An enhanced arrhythmogenic effect may occur when epinephrine is given to patients with chloral hydrate overdose or anesthetized with cyclopropane or halogenated general anesthetics.
- B. Use in patients taking propranolol and other nonselective beta blockers may produce severe hypertension owing to blockade of beta-2-mediated vasodilation, resulting in unopposed alpha-mediated vasoconstriction.
- C. Cocaine and cyclic antidepressants may enhance stimulant effects owing to inhibition of neuronal epinephrine reuptake.
- D. Monoamine oxidase inhibitors may enhance pressor effects because of decreased neuronal epinephrine metabolism.
- E. Digitalis intoxication may enhance arrhythmogenicity of epinephrine.

VI. Dosage and method of administration

- A. **Caution: Avoid extravasation.** The intravenous infusion must be free flowing, and the infused vein should be observed frequently for signs of subcutaneous infiltration (pallor, coldness, or induration).
 - 1. If extravasation occurs, immediately infiltrate the affected area with phenolamine (see p 487), 5–10 mg in 10–15 mL of normal saline (children, 0.1–0.2 mg/kg; maximum 10 mg total) via a fine (25- to 27-gauge) hypodermic needle; improvement is evidenced by hyperemia and return to normal temperature.
 - 2. Alternately, topical application of nitroglycerin paste and infiltration of terbutaline have been reported successful.
- B. **Mild to moderate allergic reaction.** Give 0.3–0.5 mg subcutaneously (SC) or IM (children, 0.01 mg/kg of 1:1000 solution or 1:200 suspension; maximum 0.5 mg). May be repeated after 10–15 minutes if needed.
- C. **Severe anaphylaxis.** Give 0.05–0.1 mg IV (0.5–1 mL of a 1:10,000 solution) every 5–10 minutes (children, 0.01 mg/kg; maximum 0.1 mg), or an IV infusion at 1–4 mcg/min. If intravenous access is not available, the endotracheal route may be used; give 0.5 mg (5 mL of a 1:10,000 solution) down the endotracheal tube.
- D. **Hypotension.** Infuse at 1 mcg/min; titrate upward every 5 minutes as necessary. If the patient has refractory hypotension and is on a beta-adrenergic blocking drug, consider glucagon (see p 449).

VII. Formulations

- A. **Parenteral.** Epinephrine hydrochloride (Adrenalin, others), 0.01 mg/mL (1:100,000), 0.1 mg/mL (1:10,000), 0.5 mg/mL (1:2000), and 1 mg/mL (1:1000), in 1-, 2-, and 30-mL ampules, vials, and prefilled syringes. Most preparations contain sodium bisulfite or sodium metabisulfite as a preservative.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 10 mg (10 ampules, 1:1000, 1 mL, or equivalent).

► ESMOLOL

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Esmolol is a short-acting, IV, cardioselective beta-adrenergic blocker with no intrinsic sympathomimetic or membrane-depressant activity. In usual therapeutic doses, it causes little or no bronchospasm in patients with asthma. Esmolol produces peak effects within 6–10 minutes of administration of an intravenous bolus. It is rapidly hydrolyzed by red blood cell esterases, with an elimination half-life of 9 minutes; therapeutic and adverse effects disappear within 30 minutes after the infusion is discontinued.

I. Indications

- A. Rapid control of supraventricular and ventricular tachyarrhythmias and hypertension, especially if caused by excessive sympathomimetic activity (eg, stimulant drugs, hyperthyroid state).
- B. Reversal of hypotension and tachycardia caused by excessive beta-adrenergic activity resulting from theophylline or caffeine overdose.
- C. Control of ventricular tachyarrhythmias caused by excessive myocardial catecholamine sensitivity (eg, chloral hydrate and chlorinated hydrocarbon solvents).

III. Contraindications

- A. Contraindications include hypotension, bradycardia, or congestive heart failure secondary to intrinsic cardiac disease or cardiac-depressant effects of drugs and toxins (eg, cyclic antidepressants and barbiturates).
- B. Hypertension caused by alpha-adrenergic or generalized stimulant drugs, unless co-administered with a vasodilator (eg, nitroprusside or phentolamine).

IV. Adverse effects

- A. Hypotension and bradycardia may occur, especially in patients with intrinsic cardiac disease or cardiac-depressant drug overdose.
- B. Bronchospasm may occur in patients with asthma or chronic bronchospasm, but it is less likely than with propranolol or other nonselective beta blockers and it is rapidly reversible after the infusion is discontinued.
- C. Esmolol may mask physiologic responses to hypoglycemia (tremor, tachycardia, and glycogenolysis) and therefore should be used with caution in patients with diabetes.
- D. **Use in pregnancy.** FDA category C (indeterminate). This does not preclude its short-term use for a seriously symptomatic patient (see p 405). High-dose infusion may contribute to placental ischemia.

V. Drug or laboratory interactions

- A. Esmolol may transiently increase the serum digoxin level by 10–20%, but the clinical significance of this is unknown.
- B. Recovery from succinylcholine-induced neuromuscular blockade may be slightly delayed (5–10 minutes). Similarly, esmolol metabolism may be inhibited by anticholinesterase agents (eg, organophosphates).
- C. Esmolol is not compatible with sodium bicarbonate solutions.

VI. Dosage and method of administration

- A. Dilute before intravenous injection to a final concentration of 10 mg/mL, with 5% dextrose, lactated Ringer's injection, or saline solutions.
- B. Give as an intravenous infusion, starting at 0.025–0.05 mg/kg/min and increasing as needed up to 0.2 mg/kg/min (average dose 0.1 mg/kg/min). Steady-state concentrations are reached approximately 30 minutes after each infusion adjustment. A loading dose of 0.5 mg/kg should be given over 1 minute if more rapid onset of clinical effects (5–10 minutes) is desired.
- C. Infusion rates greater than 0.2 mg/kg/min are likely to produce excessive hypotension. At rates greater than 0.3 mg/kg/min the beta-blocking effects lose their beta-1 selectivity.

VII. Formulations

- A. **Parenteral.** Esmolol hydrochloride (Brevibloc), 2.5 g in 10-mL ampules (250 mg/mL) and 100 mg in 10-mL vials (10 mg/mL).
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 2 ampules (250 mg/mL, 10 mL) or 25 vials (10 mg/mL, 10 mL).

► ETHANOL

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Ethanol (ethyl alcohol) acts as a competitive substrate for the enzyme alcohol dehydrogenase, preventing the metabolic formation of toxic

metabolites from methanol or ethylene glycol. Blood ethanol concentrations of 100 mg/dL, or at least a 1:4 molar ratio of ethanol to toxic alcohol/glycol, effectively saturate alcohol dehydrogenase and prevent further methanol and ethylene glycol metabolism (see also Fomepizole, p 448). Ethanol is well absorbed from the gastrointestinal tract when given orally, but the onset is more rapid and predictable when it is given intravenously. The elimination of ethanol is zero order; the average rate of decline is 15 mg/dL/h; however, this is highly variable and will be influenced by prior chronic use of alcohol, recruitment of alternate metabolic pathways, and concomitant hemodialysis (eg, to remove methanol or ethylene glycol).

II. Indications. Suspected **methanol** (methyl alcohol, see p 260) or **ethylene glycol** (see p 194) poisoning with:

- A.** A suggestive history of ingestion of a toxic dose but no available blood concentration measurements;
- B.** Metabolic acidosis and an unexplained elevated osmolar gap (see p 32); or
- C.** A serum methanol or ethylene glycol concentration ≥ 20 mg/dL.
- D. Note:** Since the introduction of fomepizole (4-methylpyrazole, see p 448), a potent inhibitor of alcohol dehydrogenase, most patients with ethylene glycol or methanol poisoning will probably be treated with this drug instead of ethanol, particularly in cases involving small children, patients taking disulfiram, patients with pancreatitis, and in hospitals lacking laboratory support to perform rapid ethanol levels (for monitoring treatment). Although ethanol is less expensive and widely available, it is more difficult to dose, requires more monitoring, and has a greater risk of adverse effects.
- E.** Other substances that are metabolized by alcohol dehydrogenase to toxic metabolites include: propylene glycol, diethylene glycol, triethylene glycol, glycol ethers (eg, ethylene glycol ethyl ether, ethylene glycol butyl ether), and 1,4-butanediol. The criteria for ethanol therapy and evidence for improved outcomes are lacking for these substances.

III. Contraindications. Use of interacting drugs, which may cause disulfiram-type reaction (see V.B, below).

IV. Adverse effects

- A.** Nausea, vomiting, and gastritis may occur with oral administration. Ethanol may also exacerbate pancreatitis.
- B.** Inebriation, sedation, and hypoglycemia (particularly in children and malnourished adults) may occur.
- C.** Intravenous use is sometimes associated with local phlebitis (especially with ethanol solutions $\geq 10\%$). Hyponatremia may result from large doses of sodium-free intravenous solutions.
- D.** Acute flushing, palpitations, and postural hypotension may occur in patients with atypical aldehyde dehydrogenase enzyme (up to 50–80% of Japanese, Chinese, and Korean individuals).
- E. Use in pregnancy.** FDA category C (indeterminate). Ethanol crosses the placenta. Chronic overuse in pregnancy is associated with birth defects (fetal alcohol syndrome). The drug reduces uterine contractions and may slow or stop labor. However, these effects do not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A.** Ethanol potentiates the effect of central nervous system–depressant drugs and hypoglycemic agents.
- B. Disulfiram reaction** (see p 186), including flushing, palpitations, and postural hypotension, may occur in patients taking disulfiram as well as a variety of other medications (eg, metronidazole, furazolidone, procarbazine, chlorpropamide, some cephalosporins, and *Coprinus* mushrooms). In such cases, fomepizole is the recommended alternative to ethanol treatment.
- C.** Drugs or chemicals metabolized by alcohol dehydrogenase (eg, chloral hydrate, isopropyl alcohol) will also have impaired elimination. Fomepizole and ethanol mutually inhibit the metabolism of each other.

TABLE III-6. ETHANOL DOSING (ADULTS AND CHILDREN)

Dose	Intravenous ^c		Oral
	5%	10%	50%
Loading ^a	15 mL/kg	7.5 mL/kg	2 mL/kg
Maintenance ^b	2–4 mL/kg/h	1–2 mL/kg/h	0.2–0.4 mL/kg/h
Maintenance during hemodialysis ^b	4–7 mL/kg/h	2–3.5 mL/kg/h	0.4–0.7 mL/kg/h

^aIf the patient's serum ethanol level is greater than 0, reduce the loading dose in a proportional manner. Multiply the calculated loading dose by the following factor:

$$\frac{100 - [\text{patient's serum ethanol in mg/dL}]}{100}$$

^bDoses may vary depending on the individual. Chronic alcoholics have a higher rate of ethanol elimination, and maintenance doses should be adjusted to maintain an ethanol level of approximately 100 mg/dL.

^cInfuse intravenous loading dose over 20–30 minutes or longer.

VI. Dosage and method of administration. Obtain serum ethanol levels after the loading dose and frequently during maintenance therapy to ensure a concentration of 100–150 mg/dL (eg, every 1–2 hours until goal achieved, eg, level = 100 mg/dL, or after change in infusion rate and then every 2–4 hours during the maintenance dosing).

- A. Ethanol may be given orally or intravenously. The desired serum concentration is 100 mg/dL (20 mmol/L); this can be achieved by giving approximately 750 mg/kg (Table III-6) as a loading dose, followed by a maintenance infusion of approximately 100–150 mg/kg/h (give a larger dose to chronic alcoholics). A 10% ethanol solution is preferred for IV (to minimize fluids, but may require central venous access in children) and a solution of less than 30% (usually 20% given for palatability and absorption) is preferred for oral administration.
- B. Increase the infusion rate to 175–250 mg/kg/h (larger dose for chronic alcoholics) during hemodialysis to offset the increased rate of ethanol elimination. Alternately, ethanol may be added to the dialysate.

VII. Formulations

- A. **Oral.** Pharmaceutical-grade ethanol (96% USP). **Note:** Commercial liquor may be used orally if pharmaceutical-grade ethanol is not available: administer 160 mL/kg divided by the “proof” of the liquor (eg, if using 80 proof liquor, give 2.0 mL/kg). Mix with juice and dilute to a concentration of 20%.
- B. **Parenteral.** Ethanol 5% in 5% dextrose solution; 10% in 5% dextrose solution in 1000 mL.
- C. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is three bottles (10% ethanol, 1 L each).

► FLUMAZENIL

Walter H. Mullen, PharmD

- I. **Pharmacology.** Flumazenil (Romazicon) is a highly selective competitive inhibitor of central nervous system benzodiazepine receptors. It has no demonstrable benzodiazepine agonist activity and no significant toxicity even in high doses. It has no effect on alcohol or opioid receptors, and it does not reverse alcohol intoxication. Flumazenil is most effective parenterally (high first-pass effect with oral administration). After intravenous administration, the onset of benzodiazepine reversal occurs within 1–2 minutes, peaks at 6–10 minutes, and lasts for

1–5 hours, depending on the dose of flumazenil and the degree of preexisting benzodiazepine effect. It is eliminated by hepatic metabolism with a serum half-life of approximately 1 hour.

II. Indications

- A. Rapid reversal of benzodiazepine overdose–induced coma and respiratory depression, both as a diagnostic aid and potential substitute for endotracheal intubation. Rule out high-risk patients (see below).
- B. Postoperative or postprocedure reversal of benzodiazepine sedation.

III. Contraindications

- A. Known hypersensitivity to flumazenil or benzodiazepines.
- B. Suspected serious cyclic antidepressant overdose.
- C. Benzodiazepine use for control of a potentially life-threatening condition (eg, status epilepticus or increased intracranial pressure).

IV. Adverse effects

- A. Anxiety, agitation, headache, dizziness, nausea, vomiting, tremor, and transient facial flushing.
- B. Rapid reversal of benzodiazepine effect in patients with benzodiazepine addiction or high tolerance may result in an acute withdrawal state, including hyperexcitability, tachycardia, and seizures (rarely reported).
- C. Seizures or arrhythmias may be precipitated in patients with a serious cyclic antidepressant overdose.
- D. Flumazenil has precipitated arrhythmias in a patient with a mixed benzodiazepine and chloral hydrate overdose.
- E. **Use in pregnancy.** FDA category C (indeterminate). This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

- V. **Drug or laboratory interactions.** No known interactions. Flumazenil does not appear to alter kinetics of benzodiazepines or other drugs.

VI. Dosage and method of administration

- A. **Benzodiazepine overdose.** Titrate the dosage until desired response is achieved.
 - 1. Administer 0.2 mg IV over 30 seconds (pediatric dose not established; start with 0.01 mg/kg). If there is no response, give 0.3 mg. If there still is no response, give 0.5 mg, and repeat every 30 seconds if needed to a total maximum dose of 3 mg (1 mg in children).
 - 2. Because effects last only 1–5 hours, continue to monitor the patient closely for resedation. If multiple repeated doses are needed, consider a continuous infusion (0.2–1 mg/h).
- B. **Reversal of conscious sedation or anesthetic doses of benzodiazepine.** A dose of 0.2 mg given intravenously is usually sufficient and may be repeated, titrating up to 1 mg.

VII. Formulations

- A. **Parenteral.** Flumazenil (Romazicon), 0.1 mg/mL, 5- and 10-mL vials with parabens and EDTA.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 10 vials (0.1 mg/mL, 10 mL).

► FOLIC ACID

F. Lee Cantrell, PharmD

- I. **Pharmacology.** Folic acid is a B-complex vitamin that is essential for protein synthesis and erythropoiesis. In addition, the administration of folate to patients with methanol poisoning may enhance the elimination of the toxic metabolite formic acid, based on studies in folate-deficient primates. **Note:** Folic acid requires metabolic activation and is not effective for treatment of poisoning by dihydrofolate reductase inhibitors (eg, methotrexate and trimethoprim). Leucovorin (see p 460) is the proper agent in these situations.

- II. **Indications.** Adjunctive treatment for methanol poisoning.
- III. **Contraindications.** No known contraindications.
- IV. **Adverse effects**
 - A. Rare allergic reactions have been reported after intravenous administration.
 - B. **Use in pregnancy.** Folic acid is a recommended supplement.
- V. **Drug or laboratory interactions.** This agent may decrease phenytoin levels by enhancing metabolism.
- VI. **Dosage and method of administration.** The dose required for methanol poisoning is not established, although 50 mg IV (children, 1 mg/kg) every 4 hours for six doses has been recommended.
- VII. **Formulations**
 - A. **Parenteral.** Sodium folate (Folvite), 5 and 10 mg/mL, 10-mL vials.
 - B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is six vials (5 mg/mL, 1 mL each).

► FOMEPIZOLE (4-METHYLPYRAZOLE, 4-MP)

Thomas E. Kearney, PharmD

- I. **Pharmacology**
 - A. Fomepizole (4-methylpyrazole) is a potent competitive inhibitor of alcohol dehydrogenase, the first enzyme in the metabolism of ethanol and other alcohols. Fomepizole can prevent the formation of toxic metabolites after methanol or ethylene glycol ingestion. Since the introduction of fomepizole, most patients with ethylene glycol or methanol poisoning will probably be treated with this drug instead of ethanol, particularly in cases involving small children, patients taking disulfiram, patients with pancreatitis, and in hospitals lacking laboratory support to perform rapid ethanol levels (for monitoring treatment). Although ethanol is less expensive and widely available, it is more difficult to dose, requires more monitoring, and has a greater risk of adverse effects.
 - B. Fomepizole is eliminated mainly via zero-order kinetics, but P-450 metabolism can undergo autoinduction within 2–3 days. The drug is dialyzable. It is well absorbed and has been used successfully with PO administration, but is not approved by this route in the United States.
- II. **Indications** are similar to those for ethanol (see p 444): suspected or confirmed **methanol** (methyl alcohol; see p 260) or **ethylene glycol** (see p 194) poisoning with one or more of the following:
 - A. A reliable history of ingestion of a toxic dose but no available blood concentration measurements (when used empirically, allows a 12-hour “window” after one dose to assess patient);
 - B. Metabolic acidosis and an unexplained elevated osmolar gap (see p 32); or
 - C. Serum methanol or ethylene glycol concentration ≥ 20 mg/dL.
 - D. Other substances that are metabolized by alcohol dehydrogenase to toxic metabolites include propylene glycol, diethylene glycol, triethylene glycol, glycol ethers (eg, ethylene glycol ethyl ether, ethylene glycol butyl ether), and 1,4-butanediol. The criteria for fomepizole therapy and evidence for improved outcomes are lacking for these substances.
 - E. Disulfiram reaction (or risk of): to halt progression or production of acetaldehyde, assuming that ethanol is still present (based on case reports).
- III. **Contraindications.** History of allergy to the drug or to other pyrazoles.
- IV. **Adverse effects**
 - A. Venous irritation and phlebosclerosis after intravenous injection of the undiluted product.

- B. Headache, nausea, and dizziness are the most commonly reported side effects. Less common effects are vomiting, tachycardia, hypotension, feeling of inebriation, rash, fever, and eosinophilia.
 - C. Transient non-dose-dependent elevation of hepatic transaminases has been reported after multiple doses.
 - D. Although safety and effectiveness in children have not been established by the manufacturer, it has been successfully used and reported for pediatric poisonings (as young as 8 months).
 - E. **Use in pregnancy.** FDA category C (indeterminate). Has been used in pregnant patients without immediate adverse effects on mother or fetus.
- V. **Drug or laboratory interactions**
- A. Drugs or chemicals metabolized by alcohol dehydrogenase (eg, chloral hydrate, ethanol, isopropyl alcohol) will also have impaired elimination. Fomepizole and ethanol mutually inhibit the metabolism of each other.
 - B. Drugs or chemicals metabolized by cytochrome P-450 enzymes may compete with fomepizole for elimination. Also, induction of P-450 activity by these drugs or by fomepizole may alter metabolism.
- VI. **Dosage and method of administration.** **Note:** The interval between the initial dose and subsequent maintenance doses, 12 hours, provides the opportunity to confirm the diagnosis with laboratory testing.
- A. **Initial dose.** Give a loading dose of 15 mg/kg (up to 1 g). Dilute in at least 100 mL of normal saline or 5% dextrose and infuse slowly over 30 minutes. **Note:** The drug may solidify at room temperature and should be visually inspected prior to administration. If there is any evidence of solidification, hold the vial under a stream of warm water or roll between the hands.
 - B. **Maintenance therapy.** Give 10 mg/kg every 12 hours for four doses, then increase to 15 mg/kg (to offset increased metabolism resulting from autoinduction) until methanol or ethylene glycol serum levels are below 20 mg/dL.
 - C. **Adjustment for hemodialysis.** To offset loss of fomepizole during dialysis, increase the frequency of dosing to every 4 hours.
- VII. **Formulations**
- A. **Parenteral.** Fomepizole (Antizol, Orphan Drug Corp.): 1 g/mL in 1.5-mL vials, prepackaged in tray packs containing four vials.
 - B. **The suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is four vials. **Note:** Orphan Drug Corp. has announced that it will replace free of charge any expired vials of fomepizole.

► GLUCAGON

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Glucagon is a polypeptide hormone that stimulates the formation of adenyl cyclase, which in turn increases the intracellular concentration of cyclic adenosine monophosphate (cAMP). This results in enhanced glycogenolysis and an elevated serum glucose concentration; vascular smooth-muscle relaxation; and positive inotropic, chronotropic, and dromotropic effects. These effects occur independently of beta-adrenergic stimulation (glucagon has a separate receptor on the myocardium). It may also increase arachidonic acid levels in cardiac tissue via an active metabolite, miniglucagon. Arachidonic acid improves cardiac contractility due to effects on calcium. Glucagon is destroyed in the gastrointestinal tract and must be given parenterally. After intravenous administration, effects are seen within 1–2 minutes and persist for 10–20 minutes. The serum half-life is about 3–10 minutes. **Note:** Glucagon is usually not considered first-line therapy for hypoglycemia due to its slow onset of action and reliance on glycogen stores). Instead, use glucose (see p 450) if available.

II. Indications

- A. Hypotension, bradycardia, or conduction impairment caused by beta-adrenergic blocker intoxication (see p 131). Also consider in patients with hypotension associated with anaphylactic or anaphylactoid reactions who may be on beta-adrenergic blocking agents.
- B. Possibly effective for severe cardiac depression caused by intoxication with calcium antagonists, tricyclic antidepressants, quinidine, or other types Ia and Ic antiarrhythmic drugs. Because of the benign side-effect profile of glucagon, consider its early empiric use in any patient with myocardial depression (bradycardia, hypotension, or low cardiac output) who does not respond rapidly to usual measures.
- C. To facilitate passage of obstructed gastric foreign bodies (eg, drug packets) through the pylorus into the intestine (based on a case report).

III. Contraindications.

Known hypersensitivity to the drug (rare), or pheochromocytoma or insulinoma.

IV. Adverse effects

- A. Hyperglycemia, hypokalemia.
- B. Nausea and vomiting by delaying gastric emptying and hypotonicity. May impact GI decontamination (activated charcoal, whole-bowel irrigation).
- C. **Use in pregnancy.** FDA category B. Fetal harm is extremely unlikely (see p 405).

V. Drug or laboratory interactions.

Concurrent administration of epinephrine potentiates and prolongs the hyperglycemic and cardiovascular effects of glucagon. It is unknown if glucagon interferes with the effectiveness of insulin and glucose therapy for severe calcium antagonist poisoning. Note that glucagon stimulates endogenous insulin secretion.

VI. Dosage and method of administration.

Give 3–10 mg IV (may also titrate with 0.05-mg/kg boluses or 3–5 mg given over 1–2 minutes and repeated every 3 minutes until response or a total of 10 mg), followed by 1–5-mg/h infusion (children, 0.15 mg/kg IV, or titrate with 0.05 mg/kg every 3 minutes, followed by 0.05–0.1 mg/kg/h). Up to 10-mg/h infusions have been used for adults. For very large doses, consider using sterile water or D5W to reconstitute, rather than the glycerine-containing diluent provided with the drug (eg, add 4 mg glucagon to 50 mL D5W for continuous infusion). Note that the optimal duration of therapy is not known and that tachyphylaxis may occur with prolonged infusions (case report with infusion duration > 24 hours).

VII. Formulations. **Note:**

Glucagon is no longer available in 10-mg vials, and instead the 1-mg kits must be used, at a considerably higher cost to attain adequate dosing for the management of poisonings.

- A. **Parenteral.** Glucagon Emergency (or Diagnostic) Kit, 1 unit (approximately 1 mg, with 1-mL syringe diluent with glycerine), and GlucaGen (Glucagon Hydrochloride) Diagnostic Kit (1 mg with 1 mL sterile water for diluent).
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 100 mg (100 kits, 1 unit each).

► GLUCOSE

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Glucose is an essential carbohydrate used as a substrate for energy production within the body. Although many organs use fatty acids as an alternative energy source, the brain is totally dependent on glucose as its major energy source; thus, hypoglycemia may rapidly cause serious brain injury. Dextrose administered with insulin shifts potassium intracellularly and maintains euglycemia for treatment of calcium antagonist poisoning (HIE therapy).

II. Indications

- A. Hypoglycemia.
- B. Empiric therapy for patients with stupor, coma, or seizures who may have unsuspected hypoglycemia.
- C. Used with an insulin infusion for severe calcium antagonist poisoning (see p 144) and hyperkalemia (p 37).

III. Contraindications. No absolute contraindications for empiric treatment of comatose patients with possible hypoglycemia. However, hyperglycemia and (possibly) recent ischemic brain injury may be aggravated by excessive glucose administration.

IV. Adverse effects

- A. Hyperglycemia and serum hyperosmolality.
- B. Local phlebitis and cellulitis after extravasation (occurs with concentrations $\geq 10\%$) from the intravenous injection site.
- C. Administration of a large glucose load may precipitate acute Wernicke-Korsakoff syndrome in thiamine-depleted patients. For this reason, thiamine (see p 505) is routinely given along with glucose to alcoholic or malnourished patients.
- D. Administration of large volumes of sodium-free dextrose solutions may contribute to fluid overload, hyponatremia, hypokalemia, and mild hypophosphatemia.
- E. **Use in pregnancy.** FDA category C (indeterminate). This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions. No known interactions.

VI. Dosage and method of administration

- A. As empiric therapy for coma, give 50–100 mL of 50% dextrose (equivalent to 25–50 g glucose) slowly (eg, about 3 mL/min) via a secure intravenous line (children, 2–4 mL/kg of 25% dextrose; do **not** use 50% dextrose in children).
- B. Persistent hypoglycemia (eg, resulting from poisoning by sulfonylurea agent) may require repeated boluses of 25% (for children) or 50% dextrose and infusion of 5–10% dextrose, titrated as needed. Consider use of octreotide (see p 480) in such situations. Note that glucose can stimulate endogenous insulin secretion, which may exacerbate a hyperinsulinemia (resulting in wide fluctuations of blood glucose levels while treating sulfonylurea poisonings).

VII. Formulations

- A. **Parenteral.** Dextrose (d-Glucose) injection, 50%, 50-mL ampules, vials, and prefilled injector; 25% dextrose, 10-mL syringes; various solutions of 2.5–70% dextrose, some in combination with saline or other crystalloids.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is four prefilled injectors (50% and 25%) and four bottles or bags (5% and 10%, 1 L each).

► HALOPERIDOL AND DROPERIDOL

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Haloperidol and droperidol are butyrophenone neuroleptic drugs useful for the management of acutely agitated psychotic patients and as antiemetics. They have strong central antidopaminergic activity and weak anticholinergic and anti- α -adrenergic effects. Haloperidol is well absorbed from the gastrointestinal tract and by the intramuscular route. Droperidol is only available for parenteral use and is also well absorbed by the intramuscular route. Droperidol has a more predictable and rapid onset of 3–10 minutes, and both have peak pharmacologic effects that occur within 30–40 minutes of an intra-

muscular injection. Both drugs are principally metabolized by the liver. The serum half-life for haloperidol is 12–24 hours.

II. Indications

- A. **Haloperidol** is used for the management of acute agitated functional psychosis or extreme agitation induced by stimulants or hallucinogenic drugs, especially when drug-induced agitation has not responded to a benzodiazepine.
- B. **Droperidol** had been recognized to have more rapid onset and greater efficacy than haloperidol (for agitation and psychosis as well as an antiemetic for drug- or toxin-induced nausea and vomiting). However, its role in routine therapy is uncertain due to reports of deaths and a new “black box” warning about QT prolongation (see IV.D, below). Therefore, other antiemetic drugs (eg, metoclopramide, see p 467; ondansetron, see p 481) should be considered as first-line drugs to control persistent nausea and vomiting.

III. Contraindications

- A. Severe central nervous system depression in the absence of airway and ventilatory control.
- B. Severe parkinsonism.
- C. Known hypersensitivity to haloperidol or droperidol.
- D. Prolonged QTc interval (prior to droperidol administration, a 12-lead EKG is recommended).

IV. Adverse effects

- A. Haloperidol and droperidol produce less sedation and less hypotension than chlorpromazine but are associated with a higher incidence of extrapyramidal side effects.
- B. Rigidity, diaphoresis, and hyperpyrexia may be a manifestation of neuroleptic malignant syndrome (see p 22) induced by haloperidol, droperidol, and other neuroleptic agents.
- C. Haloperidol lowers the seizure threshold and should be used with caution in patients with known seizure disorder or who have ingested a convulsant drug.
- D. Large doses of haloperidol can prolong the QT interval and cause torsade de pointes (see p 14). The FDA recently added a **black box warning** for droperidol that QT prolongation and torsade de pointes have occurred at or below recommended doses.
- E. Both drugs may cause orthostatic hypotension and tachycardia.
- F. Some oral haloperidol tablets contain tartrazine dye, which may precipitate allergic reactions in susceptible patients.
- G. **Use in pregnancy.** FDA category C (indeterminate). These drugs are teratogenic and fetotoxic in animals, and cross the placenta. Their safety in human pregnancy has not been established (see p 405).

V. Drug or laboratory interactions

- A. Haloperidol and droperidol potentiate central nervous system–depressant effects of opioids, antidepressants, phenothiazines, ethanol, barbiturates, and other sedatives.
- B. Combined therapy with lithium may increase the risk of neuroleptic malignant syndrome (see p 22).

VI. Dosage and method of administration

- A. **Oral.** Give 2–5 mg of haloperidol PO; repeat once if necessary; usual daily dose is 3–5 mg two to three times daily (children ≥ 3 years old, 0.05–0.15 mg/kg/day or 0.5 mg in two to three divided doses).
- B. **Parenteral. Caution:** Monitor the QT interval continuously, and treat torsade de pointes if it occurs (see p 14).
 - 1. **Haloperidol.** Give 2–5 mg of haloperidol IM; may repeat once after 20–30 minutes and hourly if necessary (children ≥ 3 years old, same as orally). Haloperidol is not approved for intravenous use in the United States, but that route has been widely used and is apparently safe (except the decanoate salt formulation).

2. **Droperidol.** Usual adult dose for delirium is 5 mg IM and sedative dose is 2.5–5.0 mg IM. For antiemetic effects, usually given 30–60 minutes as a premedication, 2.5–10 mg (children 0.088–0.165 mg/kg) IV or IM. **Note:** See warnings above; use alternate antiemetics as first-line therapy.

VII. Formulations

A. Haloperidol

1. **Oral.** Haloperidol (Haldol), 0.5-, 1-, 2-, 5-, 10-, and 20-mg tablets. 2-mg (as lactate)/mOL concentrate in 15 and 120 mL, and 5- and 10-mL unit dose.
2. **Parenteral.** Haloperidol (Haldol), 5 (as lactate) mg/mL, 1-mL ampules, syringes, and vials, and 2-, 2.5-, and 10-mL vials.

B. Droperidol (Inapsine, others), 2.5 mg/mL, 1- and 2-mL ampules or vials.

- C. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is two vials of Haloperidol (5 mg/mL, 10 mL each) and three vials of droperidol (2.5 mg/mL, 2 mL each).

► HYDROXOCOBALAMIN

Kathryn H. Meier, PharmD

- I. **Pharmacology.** Hydroxocobalamin and cyanocobalamin are synthetic forms of vitamin B₁₂ used for the treatment of pernicious anemia. Hydroxocobalamin has been recognized as an antidote for cyanide poisoning for over 40 years. Hydroxocobalamin immediately exchanges its hydroxyl group with free cyanide in the plasma to produce the nontoxic cyanocobalamin. When administered to patients with cyanide poisoning, it improves heart rate, systolic blood pressure, and acidemia. In normal individuals, hydroxocobalamin has a plasma half-life of 3–20 hours. In patients with cyanide poisoning, the half-life is 14–24 hours, and the complexed compound, cyanocobalamin, has a half-life of 6–12 hours.

II. Indications

- A. Treatment of acute cyanide poisoning or patients suspected to be high risk for cyanide poisoning (eg, smoke inhalation victims). **Note:** See VII, below.
- B. Prophylaxis against cyanide poisoning during nitroprusside infusion.

- III. **Contraindications.** Do not use in patients with a known hypersensitivity to the drug.

IV. Adverse effects

- A. Urine, sweat, tears, and other secretions become pink or red after hydroxocobalamin administration, which subsides after 3–7 days.
- B. Nausea, vomiting, hypertension, and mild muscle twitching or spasms.
- C. Allergic reactions have not yet been reported with acute intravenous therapy for cyanide poisoning. However, allergic reactions have been reported when used for chronic IM therapy.
- D. **Use in pregnancy.** No assigned FDA category; no reported experience with use during pregnancy is available. This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405), and it is probably preferable to nitrite administration for cyanide poisoning.

- V. **Drug or laboratory interactions.** Coloration of the serum sample can interfere with the following laboratory tests: falsely decreased AST and creatinine; falsely increased magnesium and bilirubin. Consider sampling for these prior to hydroxocobalamin administration.

- VI. **Dosage and method of administration.** **Note:** Not available in the United States (see VII.)

- A. **Acute cyanide poisoning.** Give 5 g (children 70 mg/kg) by IV infusion over 30 minutes; 5 g of hydroxocobalamin will neutralize approximately 40 mmol/L cyanide in blood. Doses up to 15 g have been used.

- B. Prophylaxis during nitroprusside infusion.** Administer 25 mg/h IV. **Note:** Low-strength (1 mg/mL) injection products in the United States may contain the preservative parabens. Unknown safety if parabens-containing product used.

VII. Formulations

- A. Parenteral (United States).** Hydroxocobalamin, 1 mg/mL IM; 10- and 30-mL vials (may contain parabens). The United States does not have a formulation practical to treat acute cyanide poisoning (because of preparation time and the large fluid volume required). Orphan-USA has obtained orphan drug status for hydroxocobalamin Cyanokit with no current plans to move it to market.
- B. Parenteral (non-United States).** Cyanokit contains two of the following: 2.5-g vial of freeze-dried hydroxocobalamin, 100-mL vials of sterile 0.9% sodium chloride, and a transfer device. Designed for possible field use. Available in Europe from Orphan Europe: www.orphan-europe.com.
- C.** The **suggested minimum stocking level (outside the United States)** to treat a 70-kg adult for acute cyanide poisoning is three Cyanokits (equivalent to 15 g). Note that fires often involve multiple victims.

► INAMRINONE (FORMERLY AMRINONE)

Anthony S. Manoguerra, PharmD

- I. Pharmacology.** Inamrinone is a positive inotropic agent with vasodilator activity. It is not a beta-adrenergic receptor agonist, and its exact mechanism of action is unknown. It appears to work by inhibition of myocardial cell phosphodiesterase activity, thereby increasing cellular concentrations of cyclic AMP. Cardiac afterload and preload are reduced owing to a direct vasodilator effect.
- II. Indications.** Inamrinone may be useful as a third-line inotropic agent for patients with beta-blocker, mixed beta- and alpha-blocker (eg, labetalol), or calcium antagonist overdose, when intravenous fluids, atropine, beta agonists, and glucagon have failed to restore cardiac output and blood pressure.
- III. Contraindications.** Known hypersensitivity to inamrinone or sulfites (used as a preservative).
- IV. Adverse effects**
- A.** Hypotension may result from direct vasodilator effects, especially in patients who are volume depleted. Give adequate intravenous fluids prior to and with inamrinone administration.
- B.** The formulation contains sodium metabisulfite as a preservative, which can cause acute allergic-like reactions in patients (especially asthmatics) who are sensitive to sulfites.
- C.** Inamrinone may aggravate outflow obstruction in patients with hypertrophic subaortic stenosis.
- D.** Inamrinone affects platelet survival time, resulting in a dose- and time-dependent thrombocytopenia.
- E. Use in pregnancy.** FDA category C (indeterminate). Animal studies are conflicting, and there are no good human data (see p 405). Use only if benefit justifies the potential risk (eg, a severe beta-blocker or calcium antagonist overdose unresponsive to other measures).
- F.** Name changed from amrinone to inamrinone to prevent confusion with amiodarone.
- V. Drug or laboratory interactions.** The positive inotropic effects of inamrinone are additive with other inotropic agents, including digitalis glycosides. These drugs can be used together, but the patient should be monitored for cardiac dysrhythmias.

VI. Dosage and method of administration

- A. The initial dose is 0.75 mg/kg as a bolus over 2–3 minutes. This is followed by an infusion at 5–10 mcg/kg/min.
- B. The manufacturer recommends that the total daily dose not exceed 10 mg/kg. However, up to 18 mg/kg/day has been given in some patients.

VII. Formulations

- A. Inamrinone lactate: 5 mg/mL in 20-mL ampules containing 0.25 mg/mL sodium metabisulfite as a preservative.
- B. **Suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 10 ampules.

► INSULIN

Kathy Birnbaum, PharmD

- I. **Pharmacology.** Insulin, a hormone secreted by the beta cells of the pancreas, promotes cellular uptake of glucose into skeletal and cardiac muscles and adipose tissue. In calcium antagonist poisoning, insulin may increase peripheral vascular resistance and inotropy possibly by improving glucose uptake by cardiac myocytes. Dextrose administered with insulin shifts potassium intracellularly and maintains euglycemia for treatment of calcium antagonist poisoning (hyperinsulinemia-euglycemia or “HIE” therapy). Insulin preparations are beef and pork insulin from the animal’s pancreas and human insulin biosynthetically prepared using recombinant DNA technology. The onset of action for regular insulin is 30 minutes to 1 hour and duration of action is 5–8 hours. The serum half-life of regular insulin is 4–5 minutes after IV administration.

II. Indications

- A. Hyperglycemia and diabetic ketoacidosis.
- B. Used with glucose for severe calcium antagonist poisoning (see p 144) or severe hyperkalemia (p 37).

- III. **Contraindications.** Known hypersensitivity to the drug (less frequent with human insulin).

IV. Adverse effects

- A. Hypoglycemia.
- B. Hypokalemia.
- C. Lipohypertrophy or lipoatrophy at injection site (more common with repeated use).
- D. **Use in pregnancy.** FDA category B. Human insulin does not cross the placental barrier.

V. Drug or laboratory interactions.

- A. Hypoglycemia may be potentiated by ethanol, sulfonylureas, and salicylates.
- B. Corticosteroids (by decreasing peripheral insulin resistance and promoting gluconeogenesis), glucagon (by enhanced glycogenolysis), and epinephrine (via beta-adrenergic effects) may antagonize the effects of insulin.

VI. Dosage and method of administration

- A. **Hyperglycemia.** Administer regular insulin 5–10 U IV initially, followed by infusion of 5–10 U/h, while monitoring the effect on serum glucose levels (children: administer 0.1 U/kg initially and 0.1 U/kg/h).
- B. **Hyperkalemia.** Administer regular insulin 10 U IV along with 50 mL of 50% dextrose (children: 0.1 U/kg insulin with 2 mL/kg of 25% dextrose).
- C. **Hypotension** from calcium antagonists unresponsive to conventional therapy:
 - 1. **Bolus** of regular human insulin 0.5–1 U/kg IV (average adult bolus 10–20 U IV), and if blood glucose < 200 mg/dL, give 50 mL of 50% dextrose IV (children, 0.25 g/kg of 25% dextrose).

2. **Continuous infusion.** Dilute 250 U of regular human insulin in 250 mL 0.9% saline. Follow bolus with 0.5–1 U/kg/h insulin infusion titrated above 100 as needed to increase blood pressure. Begin 10% dextrose infusion (at a rate of 1 g/kg/h) simultaneously to maintain glucose mg/dL.
3. **Monitoring.** Measure blood glucose at least every 30 minutes for first 4 hours then every hour thereafter. Monitor and replace potassium as needed to maintain potassium > 2.5 mEq/dL.

VII. Formulations

- A. **Parenteral.** Human regular insulin (Humulin R, Novulin R), 100 U/mL, 10-mL vials. Only human regular insulin can be administered intravenously.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is two 10-mL vials.

► IODIDE (POTASSIUM IODIDE, KI)

Michael A. Miller, MD

- I. **Pharmacology.** Iodine-131 is a product of fission reactions and is likely to be a major form of internal radioactive contamination following a major nuclear reactor accident or weapon detonation. Potassium iodide (KI) serves to block thyroid gland uptake of the radioactive isotopes of iodine (to prevent thyroid cancer) by both diluting the radioactive iodine as well as “filling” the gland with nontoxic iodine, effecting inhibition of further uptake. For optimal protection, KI should be administered before or at the time of exposure to inhaled radioactive iodines; however, KI may be initiated up to 3 or 4 hours after exposure. If the exposure to radioactive iodines persists, then even later administration may be of benefit.
- II. **Indications.** Potassium iodide is indicated for prevention of uptake of radioactive isotopes of iodine by the thyroid gland; therefore, when a public health emergency has occurred where sufficient exposure to radioactive iodine is likely, potassium iodide is indicated. **Note:** KI should only be used when and if directed by federal, state, or local public health officials.
- III. **Contraindications**
 - A. Known iodine allergy. Persons with the rare disorder of dermatitis herpetiformis and hypocomplementemic vasculitis are at increased risk of sensitivity.
 - B. It may be used in pregnancy, and in infants and children, but safety has not been clearly established (see IV, below).
- IV. **Adverse effects**
 - A. GI upset, diarrhea, burning of throat, metallic taste in mouth, and rarely, sialoadenitis. These effects become more common as duration of therapy and dosing increase.
 - B. Allergic reactions ranging from skin rashes to respiratory distress may occur, though life-threatening reactions are very uncommon.
 - C. Iodine-induced thyrotoxicosis, hypothyroidism, and goiter may occur, but incidence is likely less than 2% even if therapy is used for longer duration.
 - D. A bluish skin discoloration involving sweat glands may occur following large doses of iodine-containing products.
 - E. **Use in pregnancy.** FDA category D. Crosses the placental barrier and may cause hypothyroidism and goiter in the fetus. Risk is minimal with short-term use (eg, 10 days) and given long periods before term (see p 405).
- V. **Drug or laboratory interactions**
 - A. Synergistic hypothyroid activity with lithium.
 - B. TSH and free T_4 monitoring of thyroid function is reliable in the setting of standard dosing of potassium iodide.

- C. Risk of hyperkalemia with prolonged use along with other potassium supplements and potassium-sparing medications (eg, spironolactone). However, the daily dose of potassium from KI is only about 3–4 mEq.

VI. Dosage and method of administration

- A. There are several dosing guidelines put forth by varying agencies, including the US Food and Drug Administration (FDA) and the World Health Organization (WHO). Public health officials should decide upon the regimen they will use in a given situation. See <http://www.fda.gov/cder/guidance/5386fnl.htm> for a guidance document from the FDA's Center for Drug Evaluation and Research.
- B. Generally for adults >18 years, 130 mg orally every day is recommended. Oral daily doses for other ages: adolescents and children (from 3–18 years), 65 mg; 1 month to 3 years, 32 mg; 0–1 month, 16 mg.
- C. Duration of therapy may be from 1 day to many weeks depending on public health recommendations.

VII. Formulations

- A. **Oral** (Thyro-Block, others). scored tablets (130-mg and 65-mg) of potassium iodide. Formulations of potassium iodide syrups (325 mg KI/5 mL) and oral solutions such as Lugol's solution (5% iodine and 10% KI) may be found.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is one 130-mg tablet.

► IPECAC SYRUP

Anthony S. Manoguerro, PharmD

- I. **Pharmacology.** Ipecac syrup is a mixture of plant-derived alkaloids, principally emetine and cephaeline, that produce emesis by direct irritation of the stomach and by stimulation of the central chemoreceptor trigger zone. Vomiting occurs in 90% of patients, usually within 20–30 minutes. Depending on the time after ingestion of the toxin, ipecac-induced emesis removes 15–50% of the stomach contents. There is no evidence that the use of ipecac improves the clinical outcome of poisoned patients.
- II. **Indications.** For a more complete discussion of gastric decontamination, see p 47.
 - A. Early on-scene management of oral poisonings, immediately after ingestion, in the home or at health care facilities without access to activated charcoal or the capacity to perform gastric lavage.
 - B. In health care facilities, ipecac is rarely indicated but may find occasional use in patients with recent ingestions involving substances poorly adsorbed by activated charcoal (eg, iron, lithium, potassium, and sodium) or sustained-release or enteric-coated tablets.

III. Contraindications

- A. Comatose or obtunded mental state.
- B. Ingestion of a caustic or corrosive substance or sharp object.
- C. Ingestion of petroleum distillates or hydrocarbons (see p 219).
- D. Ingestion of a drug or toxin likely to result in abrupt onset of seizures or coma (eg, tricyclic antidepressants, strychnine, camphor, nicotine, cocaine, amphetamines, isoniazid).
- E. Severe hypertension.
- F. Patient at high risk for hemorrhagic diathesis (eg, coagulopathy or esophageal varices).

IV. Adverse effects

- A. Persistent gastrointestinal upset after emesis may significantly delay administration of activated charcoal or other oral antidotes.
- B. Severe and repeated vomiting may cause esophageal (Mallory-Weiss) tear, pneumomediastinum, hemorrhagic gastritis, or intracranial hemorrhage.

- C. Vomiting may stimulate vagal reflex, resulting in bradycardia or atrioventricular block.
- D. Drowsiness occurs in about 20% and diarrhea in 25% of children.
- E. Single ingestions of therapeutic doses of ipecac syrup are not toxic (the formerly used fluid extract was more potent), and failure to induce vomiting does not require removal of the ipecac. However, **chronic repeated ingestion** of ipecac (eg, in patients with bulimia) may result in accumulation of cardiotoxic alkaloids and may lead to fatal cardiomyopathy and arrhythmias.
- F. **Use in pregnancy.** FDA category C (indeterminate). There is minimal systemic absorption, but it may induce uterine contractions in late pregnancy.

V. Drug or laboratory interactions

- A. Ipecac syrup potentiates nausea and vomiting associated with the ingestion of other gastric irritants.
- B. Ipecac syrup is adsorbed in vitro by activated charcoal; however, ipecac still produces vomiting when given concurrently with charcoal.
- C. Ipecac syrup contains 1.5–2% ethanol, which may cause an adverse reaction in patients taking disulfiram (see p 186) or other agents that have disulfiram-like effects (eg, metronidazole or *Coprinus* mushrooms).

VI. Dosage and method of administration

- A. **Children 6–12 months old.** Give 5–10 mL. **Note:** Not recommended for non-health care facility use in this age group.
- B. **Children 1–12 years old.** Give 15 mL.
- C. **Adults and children over 12 years old.** Give 30 mL.
- D. Follow ipecac administration with 4–8 oz of water or clear liquid. If emesis does not occur within 30 minutes, repeat the dose of ipecac and fluid.

VII. Formulations

- A. Ipecac syrup, 30 mL.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is two 30-mL bottles.

► ISOPROTERENOL

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Isoproterenol is a catecholamine-like drug that stimulates beta-adrenergic receptors (beta-1 and -2). Pharmacologic properties include positive inotropic and chronotropic cardiac effects, peripheral vasodilation, and bronchodilation. Isoproterenol is not absorbed orally and shows variable and erratic absorption from sublingual and rectal sites. The effects of the drug are rapidly terminated by tissue uptake and metabolism; effects persist only a few minutes after intravenous injection.

II. Indications

- A. Severe bradycardia or conduction block resulting in hemodynamically significant hypotension (see p 10). **Note:** After beta-blocker overdose, even exceedingly high doses of isoproterenol may not overcome the pharmacologic blockade of beta receptors, and glucagon (see p 449) is the preferred agent.
- B. To increase heart rate and thereby abolish polymorphous ventricular tachycardia (torsade de pointes) associated with QT interval prolongation (see p 14).

III. Contraindications

- A. Do not use isoproterenol for ventricular fibrillation or ventricular tachycardia (other than torsade de pointes).
- B. Use with extreme caution in the presence of halogenated or aromatic hydrocarbon solvents or anesthetics, or chloral hydrate.

IV. Adverse effects

- A. Increased myocardial oxygen demand may result in angina pectoris or acute myocardial infarction.

- B. Peripheral beta-2-adrenergic-mediated vasodilation may worsen hypotension.
- C. The drug may precipitate ventricular arrhythmias.
- D. Sulfite preservative in some parenteral preparations may cause hypersensitivity reactions.
- E. Hypokalemia may occur secondary to beta-2-adrenergic-mediated intracellular potassium shift.
- F. **Use in pregnancy.** FDA category C (indeterminate). This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405). However, it may cause fetal ischemia and also can reduce or stop uterine contractions.

V. Drug or laboratory interactions

- A. Additive beta-adrenergic stimulation occurs in the presence of other sympathomimetic drugs, theophylline, or glucagon.
- B. Administration in the presence of cyclopropane, halogenated anesthetics, or other halogenated or aromatic hydrocarbons may enhance risk of ventricular arrhythmias because of sensitization of the myocardium to the arrhythmogenic effects of catecholamines.
- C. Digitalis-intoxicated patients are more prone to develop ventricular arrhythmias when isoproterenol is administered.
- D. Beta blockers may interfere with the action of isoproterenol by competitive blockade at beta-adrenergic receptors.

VI. Dosage and method of administration

- A. For intravenous infusion, use a solution containing 4 mcg/mL (dilute 5 mL of 1:5,000 solution in 250 mL D5W), and begin with 0.5–1 mcg/min infusion (children, 0.1 mcg/kg/min) and increase as needed for desired effect or as tolerated (by monitoring for arrhythmias). The usual upper dosage is 20 mcg/min (1.5 mcg/kg/min in children), but as high as 200 mcg/min has been given in adults with propranolol overdose. Preparations will degrade (and turn dark) with exposure to light, air, or heat.
- B. For IV bolus, the usual adult dose is 20–60 mcg (1–3 mL of a 1:50,000 solution) and repeat bolus doses of 10–200 mcg. If a dilute solution is not available, make a solution of 1:50,000 (20 mcg/mL) by diluting 1 mL of the 1:5000 solution to a volume of 10 mL with normal saline or D5W.

VII. Formulations

- A. **Parenteral.** Isoproterenol hydrochloride (Isuprel, others), 20 mcg/mL (1:50,000) or 200 mcg/mL (1:5,000), which contains sodium bisulfite or sodium metabisulfite as a preservative.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 10 ampules.

► LABETALOL

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Labetalol is a mixed alpha- and beta-adrenergic antagonist; after intravenous administration, the nonselective beta-antagonist properties are approximately sevenfold greater than the alpha-1 antagonist activity. Hemodynamic effects generally include decreases in heart rate, blood pressure, and systemic vascular resistance. Atrioventricular conduction velocity may be decreased. After intravenous injection, hypotensive effects are maximal within 10–15 minutes and persist about 2–4 hours. The drug is eliminated by hepatic metabolism and has a half-life of 5–6 hours.
- II. **Indications.** Labetalol may be used to treat hypertension and tachycardia associated with stimulant drug overdose (eg, cocaine or amphetamines). **Note:** Hypertension with bradycardia suggests excessive alpha-mediated vasoconstriction.

tion (see pp 17, 320); in this case, a pure alpha blocker such as phentolamine (p 487) is preferable, because the reversal of beta-2-mediated vasodilation may worsen hypertension.

III. Contraindications

- A. Asthma.
- B. Congestive heart failure.
- C. Atrioventricular block.

IV. Adverse effects

- A. Paradoxical hypertension may result when labetalol is used in the presence of stimulant intoxicants possessing strong mixed alpha- and beta-adrenergic agonist properties (eg, cocaine, amphetamines) owing to the relatively weak alpha-antagonist properties of labetalol compared with its beta-blocking ability. (This has been reported with propranolol but not with labetalol.)
- B. Orthostatic hypotension and negative inotropic effects may occur.
- C. Dyspnea and bronchospasm may result, particularly in asthmatics.
- D. Nausea, abdominal pain, diarrhea, tremors, dizziness, and lethargy have been reported.
- E. **Use in pregnancy.** FDA category C (indeterminate). This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A. Additive blood pressure lowering with other antihypertensive agents, halothane, or nitroglycerin.
- B. Cimetidine increases oral bioavailability of labetalol.
- C. Labetalol is incompatible with 5% sodium bicarbonate injection (forms a precipitate).
- D. Labetalol may cause false-positive elevation of urinary catecholamine levels, and it can produce a false-positive test for amphetamines on urine drug screening.

VI. Dosage and method of administration

- A. **Adult.** Give 20-mg slow (over 2 minutes) IV bolus initially; repeat with 40- to 80-mg doses at 10-minute intervals until blood pressure is controlled or a cumulative dose of 300 mg is achieved (most patients will respond to total doses of 50–200 mg). Alternatively, administer a constant infusion of 0.5–2 mg/min (adjust rate) until blood pressure is controlled or a 300-mg cumulative dose is reached. After this, give oral labetalol starting at 100 mg twice daily.
- B. **Children older than 12 years.** Initial 0.25-mg/kg dose is given intravenously over 2 minutes.

VII. Formulations

- A. **Parenteral.** Labetalol hydrochloride (Normodyne, Trandate), 5 mg/mL, 20-mL ampules, 40- and 60-mL multidose vials (with EDTA and parabens as preservative).
- B. **Oral.** Labetalol hydrochloride (Normodyne, Trandate, others), 100-, 200-, and 300-mg tablets.
- C. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is two vials (5 mg/mL, 40 mL each).

► LEUCOVORIN CALCIUM

Kathy Birnbaum, PharmD

- I. **Pharmacology.** Leucovorin (folinic acid or citrovorum factor) is a metabolically functional form of folic acid. Unlike folic acid, leucovorin does not require reduction by dihydrofolate reductase, and therefore it can participate directly in the one-carbon transfer reactions necessary for purine biosynthesis and cellular DNA and RNA production. In animal models of methanol intoxication, replace-

ment of a deficiency of leucovorin and folic acid can reduce morbidity and mortality by catalyzing the oxidation of the highly toxic metabolite formic acid to non-toxic products. However, there is no evidence that administration of these agents in the absence of a deficiency is effective.

II. Indications

A. Folic acid antagonists (eg, methotrexate, trimethoprim, and pyrimethamine). **Note:** Leucovorin treatment is essential because cells are incapable of utilizing folic acid owing to inhibition of dihydrofolate reductase.

B. Methanol poisoning. Leucovorin is an alternative to folic acid.

III. Contraindications.

No known contraindications.

IV. Adverse effects

A. Allergic reactions as a result of prior sensitization have been reported.

B. Hypercalcemia from the calcium salt may occur (limit infusion rate to 16 mL/min).

C. Use in pregnancy. FDA category C (indeterminate). This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions. Leucovorin bypasses the antifolate effect of methotrexate.

VI. Dosage and method of administration

A. Methotrexate poisoning. **Note:** *Efficacy depends on early administration; the drug should be given within 1 hour of poisoning if possible.* Administer intravenously a dose equal to or greater than the dose of methotrexate. If the dose is large but unknown, administer 75 mg (children, 10 mg/m²/dose) and then 12 mg every 6 hours for four doses. Serum methotrexate levels can be used to guide subsequent leucovorin therapy (Table III–7). Do not use oral therapy.

B. Other folic acid antagonists. Administer 5–15 mg/day IM, IV, or PO for 5–7 days.

C. Methanol poisoning. For adults and children, give 1 mg/kg (up to 50–70 mg) IV every 4 hours for one to two doses. Oral folic acid is given thereafter at the same dosage every 4–6 hours until resolution of symptoms and adequate elimination of methanol from the body (usually 2 days). Although leucovorin could be used safely for the entire course of treatment, it is no more effective than folic acid and its cost does not justify such prolonged use in place of folic acid.

VII. Formulations

A. Parenteral. Leucovorin calcium (Wellcovorin, others), 3- and 10-mg/mL vials; 50, 100, and 350 mg for reconstitution (use sterile water rather than diluent provided, which contains benzyl alcohol).

B. Oral. Leucovorin calcium (Wellcovorin, others), 5-, 10-, 15-, and 25-mg tablets.

C. The suggested minimum stocking level to treat a 70-kg adult for the first 24 hours is two 100-mg vials or one 350-mg vial.

TABLE III–7. LEUCOVORIN DOSE DETERMINATION (AFTER THE FIRST 24 HOURS)

Methotrexate Concentration (mcmol/L)	Hours After Methotrexate Exposure	Leucovorin Dose ^a (Adults and Children)
0.1–1	24	10–15 mg/m ² every 6 hours for 12 doses
1–5	24	50 mg/m ² every 6 hours until the serum level is less than 0.1 mcmol/L
5–10	24	100 mg/m ² every 6 hours until the serum level is less than 0.1 mcmol/L

Reference: Methotrexate Management, in Rumack, B H et al (eds); *Poisindex*. Denver, 1989.

^aIf serum creatinine increases by 50% in the first 24 hours after methotrexate, increase the dose frequency to every 3 hours until the methotrexate level is less than 5 mcmol/L.

► LIDOCAINE

Thomas E. Kearney, PharmD

I. Pharmacology

- A. Lidocaine is a local anesthetic and a type Ib antiarrhythmic agent. It inhibits fast sodium channels and depresses automaticity within the His-Purkinje system and the ventricles, but has a variable effect and may shorten the effective refractory period and action potential duration. Conduction within ischemic myocardial areas is depressed, abolishing reentrant circuits. Unlike quinidine and related drugs, lidocaine exerts minimal effect on the automaticity of the sinoatrial node and on conduction through the atrioventricular node and does not decrease myocardial contractility or blood pressure in usual doses. It also has rapid "on-off" binding to sodium channels (to allow reactivation of the channel) and competes with other sodium channel blockers (that are slow to release and block the channel throughout the cardiac cycle). This may account for its antiarrhythmic effect with poisonings from other sodium channel blockers (type 1a antiarrhythmics, tricyclic antidepressants).
- B. The oral bioavailability of lidocaine is poor owing to extensive first-pass hepatic metabolism (although systemic poisoning is possible from ingestion). After intravenous administration of a single dose, the onset of action is within 60–90 seconds and the duration of effect is 10–20 minutes. The elimination half-life of lidocaine is approximately 1.5–2 hours; active metabolites have elimination half-lives of 2–10 hours. Lidocaine clearance declines with continuous infusions and may be attributable to its metabolite, monoethylglycinexylidide (MEGX). Drug accumulation may occur in patients with congestive heart failure or liver or renal disease.

II. Indications. Lidocaine is used for the control of ventricular arrhythmias arising from poisoning by a variety of cardioactive drugs and toxins (eg, digoxin, cyclic antidepressants, stimulants, and theophylline). Patients with atrial arrhythmias do not usually respond to this drug.

III. Contraindications

- A. The presence of nodal or ventricular rhythms in the setting of third-degree atrioventricular or intraventricular block. These are usually reflex escape rhythms that may provide lifesaving cardiac output, and abolishing them may result in asystole.
- B. Hypersensitivity to lidocaine or other amide-type local anesthetics (rare).

IV. Adverse effects

- A. Excessive doses produce dizziness, confusion, agitation, and seizures.
- B. Conduction defects, bradycardia, and hypotension may occur with extremely high serum concentrations or in patients with underlying conduction disease.
- C. **Use in pregnancy.** FDA category B. Fetal harm is extremely unlikely (see p 405).

V. Drug or laboratory interactions

- A. Cimetidine and propranolol may decrease the hepatic clearance of lidocaine.
- B. Lidocaine may produce additive effects with other local anesthetics. In severe cocaine intoxication, lidocaine theoretically may cause additive neuronal depression.

VI. Dosage and method of administration (adults and children)

- A. Administer 1–1.5 mg/kg (usual adult dose 50–100 mg; children, 1 mg/kg) IV bolus at a rate of 25–50 mg/min, followed by infusion of 1–4 mg/min (20–50 mcg/kg/min) to maintain serum concentrations of 1.5–5 mg/L.
- B. If significant ectopy persists after the initial bolus, repeat doses of 0.5 mg/kg IV can be given if needed at 10-minute intervals (to a maximum 300 mg or 3 mg/kg total dose; children may be given repeat 1 mg/kg doses every 5–10 minutes to a maximum of 5 mg/kg).
- C. In patients with congestive heart failure or liver disease, use half the recommended maintenance infusion dose.

VII. Formulations

- A. **Parenteral.** Lidocaine hydrochloride for cardiac arrhythmias (Xylocaine, others). Direct IV: 1% (10 mg/mL), 2% (20 mg/mL) in 5-mL ampules and prefilled syringes, and 5- to 50-mL vials; 4%, 10%, and 20% in 1- and 2-g single-dose vials or additive syringes for preparing intravenous infusions; 0.2% (in 500 and 1000 mL), 0.4% (in 250 and 500 mL), and 0.8% (in 250 and 500 mL) in D5W solutions prepared for infusions.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 10 prefilled 100-mg syringes and six 1-g vials for infusions.

► MAGNESIUM

R. David West, PharmD

I. Pharmacology

- A. Magnesium is the fourth most common cation in the body, and is the second most abundant intracellular cation after potassium. Magnesium plays an essential role as an enzymatic cofactor in a number of biochemical pathways, including energy production from adenosine triphosphate (ATP).
- B. Magnesium has a direct effect on the Na^+ , K^+ -ATPase pump in both cardiac and nerve tissues. Further, magnesium has some calcium-blocking activity and may indirectly antagonize digoxin at the myocardial Na^+ , K^+ -ATPase pump.
- C. Magnesium modifies skeletal and smooth-muscle contractility. Infusions can cause vasodilation hypotension and bronchodilation. It can reduce or abolish seizures of toxemia.
- D. Magnesium is primarily an intracellular ion, and only 1% is in the extracellular fluid. A low serum Mg level under 1.2 mg/dL may indicate a net body deficit of 5000 mg or more.
- E. Hypomagnesemia can be associated with a number of acute or chronic disease processes (malabsorption, pancreatitis, DKA). It may result from chronic diuretic use or alcoholism. It is a potentially serious, life-threatening consequence of hydrofluoric acid poisoning.

II. Indications

- A. Replacement therapy for patients with hypomagnesemia.
- B. Torsade de pointes ventricular tachycardia.
- C. Barium ingestions (see p 127). Magnesium sulfate can be used orally to convert soluble barium to insoluble, nonabsorbable barium sulfate if given early.

III. Contraindications

- A. Magnesium should be administered cautiously in patients with renal impairment to avoid the potential for serious hypermagnesemia.
- B. Heart block and bradycardia.

IV. Adverse effects

- A. Flushing, sweating, hypothermia.
- B. Depression of deep tendon reflexes, flaccid paralysis, respiratory paralysis.
- C. Depression of cardiac function, hypotension, bradycardia, general circulatory collapse (in particular with rapid administration).
- D. **Use in pregnancy.** FDA category A. Magnesium sulfate is commonly used as a tocolytic agent for premature labor (see p 405).

V. Drug or laboratory interactions

- A. General CNS depressants. Additive effects may occur when CNS depressants are combined with magnesium infusions.
- B. Neuromuscular blocking agents. Concomitant administration of magnesium with neuromuscular blocking agents may enhance and prolong their effect. Dose adjustment may be needed to avoid prolonged respiratory depression.

VI. Dosage and method of administration (adults and children)

- A. Magnesium can be given orally, IV, or by IM injection. When given parenterally, the IV route is preferred.
- B. Magnesium dosing is highly empiric and is guided by both clinical response and estimated body burden of Mg based on serum levels.
- C. **Adults:** Give 1 g (8.12 mEq) every 6 h IV for four doses. For severe hypomagnesemia, doses as high as 1 mEq/kg/24 h or 8–12 g/day in divided doses have been used. Magnesium sulfate can be diluted in D5W or NS 50–100 mL and infused over 5–60 minutes. **Children:** Give 25–50 mg/kg/dose IV for three to four doses. Maximum single dose should not exceed 2000 mg (16 mEq). Higher dosages of 100 mg/kg/dose IV have also been employed.
- D. For treatment of life-threatening arrhythmias (ventricular tachycardia or fibrillation associated with hypomagnesemia) in adults, give 1–2 g (8–16 mEq) IV, which can be given over 1–2 minutes. It should be diluted to 20% or less and infused no faster than 1 g/min (see IV, above). It can also be administered as a loading dose of 1–2 g (8–16 mEq) IV diluted in 50–100 mL of D5W or NS and infused over 5 to 60 minutes. A common regimen for adults is 2 g IV over 20 minutes.
- E. For soluble barium ingestions, magnesium sulfate can be given to form insoluble, poorly absorbed barium sulfate. Adults should receive 30 g orally or by lavage and children 250 mg/kg.

VII. Formulations

- A. **Parenteral.** Magnesium sulfate vials, 50% (4.06 mEq/L, 500 mg/mL) in volumes of 2, 10, 20, and 50 mL, where 2 mL is equivalent to 1 g or 8.12 mEq. Also available in 10% (0.8 mEq/mL) and 12.5% (1 mEq/mL) in 20- and 50-mL ampules and vials, as well as large-volume premix bags. Magnesium chloride injection is also available but is less commonly used.
- B. **Oral.** A large number of oral dosage forms are available formulated in both immediate and sustained-release formulations.
- C. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is at least 12 g of parenteral magnesium sulfate.

► MANNITOL

Gary W. Everson, PharmD

I. Pharmacology

- A. Mannitol is an osmotically active solute diuretic. Mannitol inhibits water reabsorption at the loop of Henle and the proximal tubule. The increase in urine output is usually accompanied by an increase in solute excretion. In addition, mannitol transiently increases serum osmolality and decreases cerebrospinal fluid pressure by creating an osmotic gradient between brain tissue and the vascular compartment. Water moves across this gradient into the blood vessels, lowering the cerebrospinal fluid pressure and decreasing intracranial pressure.
- B. Mannitol may reverse the effects of ciguatera by osmotically reducing sodium entry into cells, causing water efflux from cells, and may act as a scavenger for hydroxyl radicals on ciguatera molecules.
- C. In the past, mannitol had been used to induce “forced diuresis” for some poisonings (eg, phenobarbital, salicylate) to enhance their renal elimination, but has been abandoned due to lack of efficacy and potential risks (cerebral and pulmonary edema).

I. Indications

- A. Proposed as a treatment for neurological and neurosensory manifestations caused by ciguatera poisoning (see p 205).

- B. Possible adjunctive agent in treating severe vitamin A toxicity associated with increased intracranial pressure (pseudotumor cerebri).
- C. Sometimes used as an adjunct to fluid therapy for acute oliguria due to massive rhabdomyolysis (see p 27).

III. Contraindications

- A. Severe dehydration.
- B. Acute intracranial bleeding.
- C. Pulmonary edema.
- D. Anuria associated with severe renal disease.

IV. Adverse effects

- A. Mannitol may cause excessive expansion of intravascular space when administered in high concentrations at a rapid rate. This may result in congestive heart failure and pulmonary edema.
- B. Mannitol causes movement of intracellular water to the extracellular space and can produce both transient hyperosmolality and hyponatremia.
- C. Oligoanuric renal failure has occurred in patients receiving mannitol. Low-dose mannitol appears to result in renal vasodilating effects, whereas high doses (> 200 g/day) may produce renal vasoconstriction.
- D. **Use in pregnancy.** FDA category C (indeterminate). This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions. No known interactions.

VI. Dosage and method of administration

- A. **Ciguatera poisoning.** Recommended dose is 1 g/kg administered IV over 30–45 minutes. Reportedly most effective when given within 1–2 days of exposure, but case reports describe alleged benefit up to 8 weeks after exposure. Ciguatera poisoning may be accompanied by dehydration that must be treated with intravenous fluids prior to administering mannitol.
- B. **Vitamin A–induced pseudotumor cerebri.** Give 0.25 g/kg up to 1 g/kg administered intravenously.

VII. Formulations

- A. **Parenteral.** Mannitol 10% (500 mL, 1000 mL); 15% (150 mL, 500 mL); 20% (250 mL, 500 mL); 25% (50-mL vials and syringes).
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is approximately 70 g (500 mL of 20% mannitol).

► METHOCARBAMOL

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Methocarbamol is a centrally acting muscle relaxant. It does not directly relax skeletal muscle, and it does not depress neuromuscular transmission or muscle excitability; muscle relaxation is probably related to its sedative effects. After intravenous administration, the onset of action is nearly immediate. Elimination occurs by hepatic metabolism, with a serum half-life of 0.9–2.2 hours.

II. Indications

- A. Control of painful muscle spasm caused by black widow spider envenomation (see p 346). Methocarbamol should be used as an adjunct to other medications (eg, morphine, diazepam) that are considered more effective.
- B. Management of muscle spasm caused by mild tetanus (see p 351) or strychnine (see p 348) poisoning.

III. Contraindications

- A. Known hypersensitivity to the drug.
- B. History of epilepsy (intravenous methocarbamol may precipitate seizures).

IV. Adverse effects

- A. Dizziness, drowsiness, nausea, flushing, and metallic taste may occur.

- B. Extravasation from an intravenous site may cause phlebitis and sloughing. Do not administer subcutaneously.
- C. Hypotension, bradycardia, and syncope have occurred after intramuscular or intravenous administration. Keep patient in a recumbent position for 10–15 minutes after injection.
- D. Urticaria and anaphylactic reactions have been reported.
- E. **Use in pregnancy.** There is no reported experience, and no FDA category has been assigned.

V. Drug or laboratory interactions

- A. Methocarbamol produces additive sedation with alcohol and other central nervous system depressants.
- B. Methocarbamol may cause false-positive urine 5-HIAA and VMA results.
- C. The urine may turn brown, black, or blue after it stands.

VI. Dosage and method of administration

A. Parenteral

1. Administer 1 g (children, 15 mg/kg) IV over 5 minutes, followed by 0.5 g in 250 mL of 5% dextrose (children, 10 mg/kg in 5 mL of 5% dextrose) over 4 hours. Repeat every 6 hours to a maximum of 3 g daily.
2. For tetanus, higher doses are usually recommended. Give 1–2 g IV initially, no faster than 300 mg/min; if needed, use a continuous infusion up to a total of 3 g.
3. The usual intramuscular dose is 500 mg every 8 hours for adults and 10 mg/kg every 8 hours for children. Do not give subcutaneously.

- B. **Oral.** Switch to oral administration as soon as tolerated. Give 0.5–1 g (children, 10–15 mg/kg) PO or by gastric tube every 6 hours. The maximum dose is 1.5 g every 6 hours; for tetanus, the maximum adult dose is 24 g/day.

VII. Formulations

- A. **Parenteral.** Methocarbamol (Robaxin, others), 100 mg/mL in 10-mL vials.
- B. **Oral.** Methocarbamol (Robaxin, others), 500- and 750-mg tablets.
- C. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 24 vials (100 mg/mL, 10 mL each).

► METHYLENE BLUE

Fabian Garza, PharmD

- I. **Pharmacology.** Methylene blue is a thiazine dye which increases the conversion of methemoglobin to hemoglobin. Methylene blue is reduced via methemoglobin reductase and NADPH to leukomethylene blue, which in turn reduces methemoglobin. G6PD (glucose-6-phosphate dehydrogenase) is essential for generation of NADPH, and is thus essential for the function of methylene blue as an antidote. Therapeutic effect is seen within 30 minutes. Methemoglobin is excreted in bile and urine, which may turn blue or green.
- II. **Indications.** Methylene blue is used to treat methemoglobinemia (see p 261), in which the patient has symptoms or signs of hypoxemia (eg, dyspnea, confusion, or chest pain) or has a methemoglobin level greater than 30%. **Note:** Methylene blue is not effective for sulfhemoglobinemia.
- III. **Contraindications**
 - A. G6PD deficiency. Treatment with methylene blue is ineffective and may cause hemolysis.
 - B. Severe renal failure.
 - C. Known hypersensitivity to methylene blue.
 - D. Methemoglobin reductase deficiency.
 - E. Reversal of nitrite-induced methemoglobinemia for treatment of cyanide poisoning.

IV. Adverse effects

- A. Gastrointestinal upset, headache, and dizziness may occur.
- B. Excessive doses of methylene blue (≥ 7 mg/kg) can actually cause methemoglobinemia by directly oxidizing hemoglobin. Doses greater than 15 mg/kg are associated with hemolysis, particularly in neonates. May also dye secretions and mucous membranes and interfere with clinical findings of cyanosis.
- C. Long-term administration may result in marked anemia.
- D. Extravasation may result in local tissue necrosis.
- E. **Use in pregnancy.** FDA category C (indeterminate). This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions.

- A. No known drug interactions, but the intravenous preparation should not be mixed with other drugs.
- B. Transient false-positive methemoglobin levels of about 15% are produced by dosages of 2 mg/kg of methylene blue. It may also alter pulse oximeter readings.

VI. Dosage and method of administration (adults and children)

- A. Administer 1–2 mg/kg (0.1–0.2 mL/kg of 1% solution) IV slowly over 5 minutes. May be repeated in 30–60 minutes.
- B. If no response after two doses, do not repeat dosing; consider G6PD deficiency or methemoglobin reductase deficiency.
- C. Patients with continued production of methemoglobin from a long-acting oxidant stress (eg, dapsone) may require repeated dosing every 6–8 hours for 2–3 days.
- D. Flush IV line with 15–30 mL of normal saline to reduce incidence of local pain.

VII. Formulations

- A. **Parenteral.** Methylene blue injection 1% (10 mg/mL).
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is five ampules (10 mg/mL, 10 mL each).

► METOCLOPRAMIDE

Judith A. Alsop, PharmD

- I. **Pharmacology.** Metoclopramide is a dopamine antagonist with antiemetic activity at the chemoreceptor trigger zone. It also accelerates gastrointestinal motility and facilitates gastric emptying. The onset of effect is 1–3 minutes after intravenous administration, and therapeutic effects persist for 1–2 hours after a single dose. The drug is excreted primarily by the kidney. The elimination half-life is about 5–6 hours but may be as long as 14 hours in patients with renal insufficiency.

II. Indications

- A. Metoclopramide is used to prevent and control persistent nausea and vomiting, particularly when the ability to administer activated charcoal (eg, treatment of theophylline poisoning) or other oral antidotal therapy (eg, acetylcysteine for acetaminophen poisoning) is compromised.
- B. Theoretical (unproved) use to stimulate bowel activity in patients with ileus who require repeat-dose activated charcoal or whole-bowel irrigation.

III. Contraindications

- A. Known hypersensitivity to the drug; possible cross-sensitivity with procainamide.
- B. Mechanical bowel obstruction or intestinal perforation.
- C. Pheochromocytoma (metoclopramide may cause hypertensive crisis).

IV. Adverse effects

- A. Sedation, restlessness, fatigue, and diarrhea may occur.

- B. Extrapyramidal reactions may result, particularly with high-dose treatment. Pediatric patients appear to be more susceptible. These reactions may be prevented by pretreatment with diphenhydramine (see p 436).
- C. May increase the frequency and severity of seizures in patients with seizure disorders.
- D. Parenteral formulations that contain sulfite preservatives may precipitate bronchospasm in susceptible individuals.
- E. **Use in pregnancy.** FDA category B. Not likely to cause harm when used as short-term therapy (see p 405).

V. Drug or laboratory interactions

- A. Additive sedation in the presence of other central nervous system depressants.
- B. Risk of extrapyramidal reactions may be increased in the presence of other dopamine antagonist agents (eg, haloperidol or phenothiazines).
- C. In one study involving hypertensive patients, metoclopramide enhanced the release of catecholamines. As a result, the manufacturer advises cautious use in hypertensive patients and suggests that the drug should not be used in patients taking monoamine oxidase (MAO) inhibitors.
- D. The drug may enhance the absorption of ingested drugs by promoting gastric emptying.
- E. Anticholinergic agents may inhibit bowel motility effects.

VI. Dosage and method of administration

- A. **Low-dose therapy.** Effective for mild nausea and vomiting. Give 10–20 mg IM or slowly IV (children, 0.1 mg/kg).
- B. **High-dose therapy.** For control of severe or persistent vomiting. For adults and children, give 1–2 mg/kg IV infusion over 15 minutes in 50 mL dextrose or saline. May be repeated twice at 2- to 3-hour intervals.
 - 1. Metoclopramide is most effective if given before emesis or 30 minutes before administration of a nausea-inducing drug (eg, acetylcysteine).
 - 2. If no response to initial dose, may give additional 2 mg/kg, and repeat every 2–3 hours up to maximum 12 mg/kg total dose.
 - 3. Pretreatment with 50 mg (children, 1 mg/kg) of diphenhydramine (see p 436) helps to prevent extrapyramidal reactions.
 - 4. Reduce dose by one-half in patients with renal insufficiency.

VII. Formulations

- A. **Parenteral.** Metoclopramide hydrochloride (Reglan), 5 mg/mL; 2-, 10-, 30-, 50-, and 100-mL vials. Also available in preservative-free 2-, 10-, and 30-mL vials and 2- and 10-mL ampules.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 1000 mg (four vials, 50 mL each, or equivalent).

► MORPHINE

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Morphine is the principal alkaloid of opium and is a potent analgesic and sedative agent. In addition, it decreases venous tone and systemic vascular resistance, resulting in reduced preload and afterload. Morphine is variably absorbed from the gastrointestinal tract and is usually used parenterally. After intravenous injection, peak analgesia is attained within 20 minutes and usually lasts 3–5 hours. Morphine is eliminated by hepatic metabolism, with a serum half-life of about 3 hours; however, the clearance of morphine is slowed, and duration of effect is prolonged in patients with renal failure.
- II. **Indications**
 - A. Severe pain associated with black widow spider envenomation, rattlesnake envenomation, or other bites or stings.
 - B. Pain caused by corrosive injury to the eyes, skin, or gastrointestinal tract.

- C. Pulmonary edema resulting from congestive heart failure. Chemical-induced noncardiogenic pulmonary edema is **not** an indication for morphine therapy.

III. Contraindications

- A. Known hypersensitivity to morphine.
- B. Respiratory or central nervous system depression with impending respiratory failure, unless the patient is intubated or equipment and trained personnel are standing by for intervention if necessary.
- C. Suspected head injury. Morphine may obscure or cause exaggerated central nervous system depression.

IV. Adverse effects

- A. Respiratory and central nervous system depression may result in respiratory arrest. Depressant effects may be prolonged in patients with liver disease and chronic renal failure.
- B. Hypotension may occur owing to decreased systemic vascular resistance and venous tone.
- C. Nausea, vomiting, and constipation may occur.
- D. Bradycardia, wheezing, flushing, pruritus, urticaria, and other histamine-like effects may occur.
- E. **Use in pregnancy.** FDA category C (indeterminate). This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A. Additive depressant effects with other opioid agonists, ethanol and other sedative-hypnotic agents, tranquilizers, and antidepressants.
- B. Morphine is physically incompatible with solutions containing a variety of drugs, including aminophylline, phenytoin, phenobarbital, and sodium bicarbonate.

VI. Dosage and method of administration

- A. Morphine may be injected subcutaneously, intramuscularly, or intravenously. The oral and rectal routes produce erratic absorption and are not recommended for use in acutely ill patients.
- B. The usual initial dose is 5–10 mg IV or 10–15 mg SC or IM, with maintenance analgesic doses of 5–20 mg every 4 hours. The pediatric dose is 0.1–0.2 mg/kg every 4 hours.

VII. Formulations

- A. **Parenteral.** Morphine sulfate for injection; variety of available concentrations from 0.5 to 50 mg/mL.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 150 mg.

► NALOXONE AND NALMEFENE

Terry Carlson, PharmD

- I. **Pharmacology.** Naloxone and nalmeferene are pure opioid antagonists that competitively block mu, kappa, and delta opiate receptors within the central nervous system. They have no opioid agonist properties and can be given safely in large doses without producing respiratory or central nervous system depression. **Naltrexone** is another potent competitive opioid antagonist that is active orally and is used to prevent relapse in patients detoxified from opioid abuse. It has also been used to reduce craving for alcohol. It is **not** used for the acute reversal of opioid intoxication, and will not be discussed further in this handbook.
- A. **Naloxone**, a synthetic *N*-allyl derivative of oxymorphone, undergoes extensive first-pass metabolism and is not effective orally but may be given subcutaneously, intramuscularly, intravenously, or even endotracheally. After intravenous administration, opioid antagonism occurs within 1–2 minutes and persists for approximately 1–4 hours. The plasma half-life ranges from 31 to 80 minutes.

- B. Nalmefene**, an injectable methylene analog of naltrexone, was approved in 1995. It is 4 times more potent than naloxone at mu receptors and slightly more potent at kappa receptors. It has a longer elimination half-life (ranging from approximately 8 to 11 hours after IV dosing), and has a duration of action of 1–4 hours (see Table III–8). The prolonged effects of nalmefene are related to the slow dissociation from the opioid receptor, which is not reflected in the AUC plasma curve.
- II. Indications**
- A.** Reversal of acute opioid intoxication manifested by coma, respiratory depression, or hypotension.
 - B.** Empiric therapy for stupor or coma suspected to be caused by opioid overdose.
 - C.** Anecdotal reports suggest that high-dose naloxone may partially reverse the central nervous system and respiratory depression associated with clonidine (see p 169), ethanol (see p 190), benzodiazepine (see p 130), or valproic acid (see p 362) overdoses, although these effects are inconsistent.
- III. Contraindications.** Do not use in patients with a known hypersensitivity to either agent (may have cross-sensitivity).
- IV. Adverse effects.** Human studies have documented an excellent safety record for both drugs. Volunteers have received up to 24 mg nalmefene intravenously and 50 mg orally.
- A.** Use in opiate-dependent patients may precipitate acute withdrawal syndrome. This may be more protracted with nalmefene. Neonates of addicted mothers may suffer more severe withdrawal symptoms, including seizures.
 - B.** Pulmonary edema or ventricular fibrillation has occasionally occurred shortly after naloxone administration in opioid-intoxicated patients. Pulmonary edema has also been associated with postanesthetic use of naloxone, especially when catecholamines and large fluid volumes have been administered. Pulmonary edema has been reported after IV nalmefene.
 - C.** Reversing the sedative effects of an opioid may amplify the toxic effects of other drugs. For example, agitation, hypertension, and ventricular irritability have occurred after naloxone administration to persons high on “speedball” (heroin plus cocaine or methamphetamine).
 - D.** Seizures have been associated with nalmefene use in animal studies but have not been reported in humans.
 - E.** There has been one case report of hypertension following naloxone administration in a patient with clonidine overdose.
 - F. Use in pregnancy.** FDA category B (see p 405). Naloxone- or nalmefene-induced drug withdrawal syndrome may precipitate labor in an opioid-dependent mother.

TABLE III–8. CHARACTERISTICS OF NALOXONE AND NALMEFENE

	Naloxone	Nalmefene
Elimination half-life	60–90 min	10–13 h
Duration of action	1 h	1–4 h ^a
Metabolism	Liver (glucuronidation)	Liver (glucuronidation)
Advantages	Lower cost; shorter action; more human experience	Longer duration lowers risk of recurrent respiratory depression for most (but not all) opioids
Disadvantages	More frequent dosing or constant infusion	Cost; may cause prolonged opioid withdrawal

^aHigh doses (eg, > 6 mg) may increase the duration of action but are not recommended at this time.

V. Drug or laboratory interactions. Naloxone and nalmefene antagonize the analgesic effect of opioids. Naloxone is not associated with a positive enzymatic urine screen for opiates.

VI. Dosage and method of administration for suspected opioid-induced coma

A. Naloxone. Administer 0.4–2 mg IV; repeat at 2- to 3-minute intervals until desired response is achieved. Titrate carefully in opioid-dependent patients (start at 0.05 mg). The dose for children is the same as for adults.

1. The total dose required to reverse the effects of the opioid is highly variable and is dependent on the concentration and receptor affinity of the opioid. Some drugs (eg, propoxyphene, diphenoxylate/atropine [Lomotil], buprenorphine, pentazocine, and the fentanyl derivatives) do not respond to usual doses of naloxone. However, if no response is achieved by a total dose of 10–15 mg, the diagnosis of opioid overdose should be questioned.
2. **Caution:** Resedation can occur when the naloxone wears off in 1–2 hours. Repeated doses of naloxone may be required to maintain reversal of the effects of opioids with prolonged elimination half-lives (eg, methadone) or sustained-release formulations or when packets or vials have been ingested.
3. **Infusion.** Give 0.4–0.8 mg/h in normal saline or 5% dextrose, titrated to clinical effect (in infants, start with 0.04–0.16 mg/kg/h). Another method is to estimate two-thirds of the initial dose needed to awaken the patient and give this amount each hour.

B. Nalmefene. In a non-opioid-dependent adult, give an initial dose of 0.5 mg/70 kg, followed by 1.0 mg/70 kg 2–5 minutes later. No added benefit of dosage higher than 1.5 mg/70 kg has been established. If opioid dependency is suspected, give a challenge dose of 0.1 mg/70 kg, followed by a 2-minute wait for signs or symptoms of opioid withdrawal (nausea, chills, myalgia, dysphoria, abdominal cramps, joint pain). If there is no indication of withdrawal, give standard doses. The effect of the drug may be prolonged in patients with end-stage renal failure or hepatic disease.

1. Dosage, safety, and efficacy in children have not been established. However, it has been shown to be safe and effective in reversing procedural sedation in children when given in postoperative incremental doses of 0.25 mcg/kg every 2–5 minutes to a maximum total dose of 1 mcg/kg. Nalmefene has similar pharmacokinetics in children as in adults.
 2. As with naloxone, the total dose required to reverse the effects of the opioid is highly variable.
 3. **Caution:** The duration of action of nalmefene will vary depending on the half-life and concentration of the opioid being reversed, the presence of other sedating drugs, and the dose of nalmefene. Smaller doses of nalmefene may have a shorter duration because of rapid redistribution of the drug out of the brain. Fully reversing doses (1–1.5 mg in a 70-kg person) have been shown to last several hours. However, this may not be long enough for patients who have overdosed on a long-acting opioid such as methadone or who have ingested a drug-containing condom or packet with unpredictable breakage and absorption.
- C. Note:** While both drugs can be given by the intramuscular or subcutaneous route, absorption is erratic and incomplete. Naloxone is not effective orally. Huge doses of nalmefene have been used orally in experimental studies, but this route is not recommended at this time.

VII. Formulations

A. Naloxone hydrochloride (Narcan): 0.02, 0.4, or 1 mg/mL; 1-, 2-, or 10-mL syringes, ampules, or vials. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 30 mg (three vials, 1 mg/mL, 10 mL each, or equivalent).

B. Nalmefene hydrochloride (Revex): 100 mcg in 1-mL ampules (blue label); 1 mg/mL in 2-mL vials (green label); syringes containing 2 mL of 1 mg/mL

nalmefene. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 16 mg (eight vials, 1 mg/mL, 2 mL each, or equivalent).

► NEUROMUSCULAR BLOCKERS

Thomas E. Kearney, PharmD

I. Pharmacology

- A. Neuromuscular blocking agents produce skeletal muscle paralysis by inhibiting the action of acetylcholine at the neuromuscular junction. **Depolarizing agents** (eg, succinylcholine; Table III–9) depolarize the motor end plate and block recovery; transient muscle fasciculations occur with the initial depolarization. **Nondepolarizing agents** (eg, atracurium, pancuronium, and others; Table III–9) are classified as either a benzylisoquinolinium diester (eg, mivacurium, atracurium) or an aminosteroid (eg, vecuronium, rocuronium) and competitively block the action of acetylcholine at the motor end plate; therefore, no initial muscle fasciculations occur. They also block acetylcholine at sympathetic ganglia, which may result in hypotension.
- B. The neuromuscular blockers produce complete muscle paralysis with no depression of central nervous system function (they are positively charged and water-soluble compounds that do not rapidly cross the brain-blood barrier). Thus, patients who are conscious will remain awake but unable to move and patients with status epilepticus may continue to have central nervous system seizure activity despite flaccid paralysis. Furthermore, they do not relieve pain or anxiety.
- C. Succinylcholine produces the most rapid onset of effects, with total paralysis within 30–60 seconds after intravenous administration. It is rapidly hydrolyzed by plasma cholinesterases, and its effects dissipate in 10–20 minutes. Rocuronium, a nondepolarizing agent, also offers a rapid onset for rapid sequence intubations. Onset and duration of several other neuromuscular blockers are described in Table III–9.

II. Indications

- A. Neuromuscular blockers are used to abolish excessive muscular activity, rigidity, or peripheral seizure activity when continued hyperactivity may produce or aggravate rhabdomyolysis and hyperthermia. Examples of such situations include the following. **Note:** The preferred agent for these conditions is a nondepolarizing agent.
 - 1. Drug overdoses involving stimulants (eg, amphetamines, cocaine, phenylcyclidine, monoamine oxidase inhibitors) or strychnine.
 - 2. Tetanus.
 - 3. Hyperthermia associated with muscle rigidity or hyperactivity (eg, status epilepticus, neuroleptic malignant syndrome, or serotonin syndrome; see p 21). **Note:** Neuromuscular blockers are not effective for malignant hyperthermia (see p 22); in fact, inability to induce paralysis with these agents should suggest the diagnosis of malignant hyperthermia.
- B. Neuromuscular blockers provide prompt flaccid paralysis to facilitate orotracheal intubation. The preferred agents for this purpose are rapid-onset agents such as succinylcholine, rapacurium, mivacurium, rocuronium, and vecuronium. They also are used to treat laryngospasm.

III. Contraindications

- A. Lack of preparedness or inability to intubate the trachea and ventilate the patient after total paralysis ensues. Proper equipment and trained personnel must be assembled before the drug is given.
- B. Known history of malignant hyperthermia. Succinylcholine use is associated with malignant hyperthermia in susceptible patients (incidence, approximately 1 in 50,000 in adults and 1 in 10,000 in children).

TABLE III-9. SELECTED NEUROMUSCULAR BLOCKERS

Drug	Classification	Onset	Duration ^a	Dose (all are intravenous)
Depolarizing Succinylcholine	Depolarizer	0.5–1 min	2–3 min	0.6 mg/kg ^b (children: 1 mg/kg ^c) over 10–20 seconds; repeat as needed.
Nondepolarizing Atracurium	Benzylisoquinolinium	3–5 min	20–45 min	0.4–0.5 mg/kg (children < 2 years: 0.3–0.4 mg/kg).
Cisatracurium	Benzylisoquinolinium	1.5–2 min	55–61 min	0.15–0.2 mg/kg (children 2–12 years: 0.1 mg/kg); then 1–3 mcg/kg/min to maintain blockade.
Pancuronium	Aminosteroid	2–3 min	35–45 min	0.06–0.1 mg/kg; then 0.01–0.02 mg/kg every 20–40 min as needed to maintain blockade.
Rocuronium	Aminosteroid	0.5–3 min	22–94 min	0.6–1 mg/kg; then 0.01 mg/kg/min to maintain blockade.
Vecuronium	Aminosteroid	1–2 min	25–40 min	For children > 1 year and adults: 0.08–0.1 mg/kg bolus; then 0.01–0.02 mg/kg every 10–20 min to maintain blockade.
Doxacurium	Benzylisoquinolinium	5–7 min	56–160 min	0.05–0.8 mg/kg (children 0.03–0.05 mg/kg); then 0.005–0.01 mg/kg every 30–45 min to maintain blockade (children may require more frequent dosing).
Pipecuronium	Aminosteroid	3–5 min	17–175 min	0.05–0.1 mg/kg (adjust for renal function); then 0.01–0.015 mg/kg every 17–175 min (children may be less sensitive and require more frequent dosing).
Mivacurium	Benzylisoquinolinium	2–4 min	13–23 min	0.15–0.25 mg/kg (children 0.2 mg/kg); then 0.1 mg/kg every 15 min, or by continuous infusion and start with 0.01 mg/kg/min and maintain with average adult dose of 0.006–0.007 mg/kg/min (children 0.014 mg/kg/min).

^aFor most agents, onset and duration is dose- and age-dependent. With succinylcholine or mivacurium, effects may be prolonged in patients who have genetic plasma cholinesterase deficiency or organophosphate intoxication.

^bTo prevent fasciculations, administer a small dose of a nondepolarizing agent (eg, pancuronium, 0.01 mg/kg) 2–3 min before the succinylcholine.

^cPretreat children with atropine at 0.005–0.01 mg/kg to prevent bradycardia or atrioventricular block.

- C. Known hypersensitivity or anaphylactic reaction (non-dose-related) to agent or preservative (eg, benzyl alcohol). Succinylcholine is most commonly implicated, but anaphylaxis has been reported with rocuronium, atracurium, mivacurium, and cisatracurium.

IV. Adverse effects

- A. Complete paralysis results in respiratory depression and apnea.
- B. Succinylcholine can stimulate vagal nerves, resulting in sinus bradycardia and atrioventricular block. Children are particularly sensitive to vagotonic effects (can prevent with atropine).
- C. Muscle fasciculations may cause increased intraocular and intragastric pressure (the latter of which may result in emesis and aspiration of gastric contents). Rhabdomyolysis and myoglobinuria may be observed, especially in children.
- D. Succinylcholine may produce hyperkalemia in patients with neuropathy, myopathy, recent severe burns, or head and spinal cord injury (this risk is maximal a few months after the injury). The mechanism is increased extrajunctional muscle acetylcholine receptors and may also occur with prolonged use of nondepolarizing agents.
- E. Clinically significant histamine release with bronchospasm may occur, especially with succinylcholine, the benzylisoquinolinium mivacurium, and the aminosteroid rapacuronium (which was withdrawn from the market). It is more common with smokers and patients with reversible airway disease.
- F. Neuromuscular blockade is potentiated by hypokalemia and hypocalcemia (nondepolarizing agents) and by hypermagnesemia (depolarizing and nondepolarizing agents).
- G. Prolonged effects may occur after succinylcholine use in patients with genetic deficiency of plasma cholinesterase.
- H. Prolonged effects may occur in patients with neuromuscular disease (eg, myasthenia gravis, Eaton-Lambert syndrome) or resistance (eg, myasthenia gravis and succinylcholine).
 - I. Tachycardia due to vagal block and sympathomimetic effects from pancuronium and high-dose rocuronium.
- J. Neuropathies, myopathies, and persistent muscular weakness associated with prolonged use due to chemical denervation.
- K. **Use in pregnancy.** FDA category C (indeterminate). This does not preclude their acute, short-term use for a seriously ill patient (see p 405).

V. Drug or laboratory interactions

- A. Actions of the nondepolarizing agents are potentiated by ether, methoxyflurane, and enflurane and are inhibited or reversed by anticholinesterase agents (eg, neostigmine, physostigmine, and carbamate and organophosphate insecticides).
- B. Organophosphate or carbamate (see p 291) insecticide intoxication may potentiate or prolong the effect of succinylcholine.
- C. Numerous drugs may potentiate neuromuscular blockade. These include calcium antagonists, dantrolene, aminoglycoside antibiotics, propranolol, membrane-stabilizing drugs (eg, quinidine), magnesium, lithium, and thiazide diuretics.
- D. Anticonvulsants (carbamazepine and phenytoin) and theophylline may delay the onset and shorten the duration of action of some nondepolarizing agents. Carbamazepine has additive effects, and reduction of the neuromuscular blocker dose may be required.
- E. Dysrhythmias are possible with myocardial sensitizers (eg, halothane) and sympathetic stimulating agents (eg, pancuronium).

VI. Dosage and method of administration (see Table III-9)

VII. Formulations

- A. **Succinylcholine chloride** (Anectine and others), 20, 50, and 100 mg/mL; 5- and 10-mL vials (with parabens and benzyl alcohol) and ampules; (100 mg) in 5-mL syringe; 500 mg and 1 g (powder for infusion). The **suggested mini-**

num stocking level to treat a 70-kg adult for the first 24 hours is two vials of each concentration.

- B. **Atracurium besylate** (Tracrium), 10 mg/mL in 5-mL single-dose and 10-mL multidose vials (with benzyl alcohol). The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is four 10-mL vials.
- C. **Cisatracurium besylate** (Nimbex), 2 mg/mL in 5- and 10-mL vials; 10 mg/mL in 20-mL vials (with benzyl alcohol). The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is one 20-mL vial or equivalent.
- D. **Pancuronium bromide** (Pavulon, others), 1 and 2 mg/mL in 2-, 5-, and 10-mL vials, ampules (some with benzyl alcohol), and syringes. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is eight vials (2 mg/mL, 5 mL each).
- E. **Rocuronium bromide** (Zemuron), 10 mg/mL in 5-mL vials. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is seven vials.
- F. **Vecuronium bromide** (Norcuron, others), 10-mg vials of lyophilized powder for reconstitution (Norcuron contains mannitol and diluent may contain benzyl alcohol). The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is three vials.
- G. **Doxacurium chloride** (Nuromax), 1 mg/mL in 5-mL vials (with benzyl alcohol). The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is three vials.
- H. **Pipecuronium bromide** (Arduan) 10 mg in 10-mL vials (powder for injection). The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is two vials.
- I. **Mivacurium chloride** (Mivacron) 0.5 mg/mL and 2 mg/mL in 5- and 10-mL single-use vials. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is four 10-mL vials or equivalent.

► NICOTINAMIDE (NIACINAMIDE)

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Nicotinamide (niacinamide, vitamin B₃), one of the B vitamins, is required for the functioning of the coenzymes nicotinamide adenine dinucleotide (NAD) and nicotinamide adenine dinucleotide phosphate (NADP). NAD and NADP are responsible for energy transfer reactions. Niacin deficiency, which results in pellagra, can be corrected with nicotinamide.
- II. **Indications.** Nicotinamide is used to prevent the neurologic and endocrinologic toxicity associated with the ingestion of Vacor (PNU), a rodenticide that is believed to act by antagonizing nicotinamide (see p 361). Best results are achieved when nicotinamide therapy is instituted within 3 hours of ingestion. It may also be effective for treatment of Vacor analogs such as alloxan and streptozocin.
- III. **Contraindications.** No known contraindications.
- IV. **Adverse effects**
 - A. Headache and dizziness.
 - B. Hyperglycemia.
 - C. Hepatotoxicity (reported after chronic use with daily dose ≥ 3 g).
 - D. **Use in pregnancy.** No assigned FDA category. This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).
- V. **Drug or laboratory interactions.** No known interactions.
- VI. **Dosage and method of administration (adults and children).** **Note:** The parenteral preparation is no longer available in the United States. The oral form may be substituted, but is of unknown efficacy.
 - 1. Give 500 mg IV initially, followed by 100–200 mg IV every 4 hours for 48 hours. Then give 100 mg orally 3–5 times daily for 2 weeks. If clinical de-

terioration from the Vacor progresses during initial therapy with nicotinamide, change dosing interval to every 2 hours. The maximum suggested daily dose is 3 g.

2. **Note:** Nicotinic acid (niacin) is **not** a substitute for nicotinamide in the treatment of Vacor ingestions.

VII. Formulations

- A. **Parenteral.** Niacinamide, 100 mg/mL (not available in the United States).
- B. **Oral.** Niacinamide, 100- and 500-mg tablets. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 3 g.

► NITRITE, SODIUM AND AMYL

Walter H. Mullen, PharmD

- I. **Pharmacology.** Sodium nitrite injectable solution and amyl nitrite crushable ampules for inhalation are components of the cyanide antidote package. The value of nitrites as an antidote to cyanide poisoning is twofold: they oxidize hemoglobin to methemoglobin, which binds free cyanide, and they may enhance endothelial cyanide detoxification by producing vasodilation. Inhalation of an ampule of amyl nitrite produces a methemoglobin level of about 5%. Intravenous administration of a single dose of sodium nitrite is anticipated to produce a methemoglobin level of about 20–30%.

II. Indications

- A. Symptomatic cyanide poisoning (see p 177). Nitrites are not usually used for empiric treatment unless cyanide is very strongly suspected, and they are not recommended for smoke inhalation victims.
- B. Nitrites are possibly effective for hydrogen sulfide poisoning if given within 30 minutes of exposure (see p 224).

III. Contraindications

- A. Significant preexisting methemoglobinemia (>40%).
- B. Severe hypotension is a relative contraindication as it may be worsened by nitrites.
- C. Administration to patients with concurrent carbon monoxide poisoning is a relative contraindication; generation of methemoglobin may further compromise oxygen transport to the tissues. Hydroxocobalamin (see p 453) has supplanted the use of nitrites for smoke inhalation victims (patients often have mixed carbon monoxide and cyanide poisoning) in countries where available.

IV. Adverse effects

- A. Headache, facial flushing, dizziness, nausea, vomiting, tachycardia, and sweating may occur. These side effects may be masked by the symptoms of cyanide poisoning.
- B. Rapid intravenous administration may result in hypotension.
- C. Excessive and potentially fatal methemoglobinemia may result.
- D. **Use in pregnancy.** No assigned FDA category. These agents may compromise blood flow and oxygen delivery to the fetus, and they may induce fetal methemoglobinemia. Fetal hemoglobin is more sensitive to the oxidant effects of nitrites. However, this does not preclude their acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A. Hypotension may be exacerbated by the concurrent presence of alcohol or other vasodilators, or any antihypertensive agent.
- B. Methylene blue should not be administered to a cyanide-poisoned patient because it may reverse nitrite-induced methemoglobinemia and theoretically result in release of free cyanide ions. However, it may be considered when severe and life-threatening excessive methemoglobinemia (eg, $\geq 70\%$) is present.

TABLE III-10. PEDIATRIC DOSING OF SODIUM NITRITE BASED ON HEMOGLOBIN CONCENTRATION

Hemoglobin (g/dL)	Initial Dose (mg/kg)	Initial Dose of 3% Sodium Nitrite (mL/kg)
7	5.8	0.19
8	6.6	0.22
9	7.5	0.25
10	8.3	0.27
11	9.1	0.3
12	10	0.33
13	10.8	0.36
14	11.6	0.39

- C. Binding of methemoglobin to cyanide (cyanomethemoglobin) may lower the measured free methemoglobin level.

VI. Dosage and method of administration

- A. **Amyl nitrite crushable ampules.** Crush one to two ampules in gauze, cloth, or a sponge and place under the nose of the victim, who should inhale deeply for 30 seconds. Rest for 30 seconds, then repeat. Each ampule lasts about 2–3 minutes. If the victim is receiving respiratory support, place the ampules in the facemask or port access to the endotracheal tube. Stop ampule use when administering intravenous sodium nitrite.

B. Sodium nitrite parenteral

1. **Adults.** Administer 300 mg of sodium nitrite (10 mL of 3% solution) IV over 3–5 minutes.
2. **Children.** Give 0.15–0.33 mL/kg to a maximum of 10 mL. Pediatric dosing should be based on the hemoglobin concentration, if known (see Table III-10). If anemia is suspected or hypotension is present, start with the lower dose, dilute in 50–100 mL of saline, and give over at least 5 minutes.
3. Oxidation of hemoglobin to methemoglobin occurs within 30 minutes. If no response to treatment occurs within 30 minutes, an additional half-sized dose of intravenous sodium nitrite may be given.

VII. Formulations

- A. **Amyl nitrite.** A component of the cyanide antidote package, 0.3 mL in crushable ampules, 12 per kit. The drug may also be acquired separately in aspirols. **Note:** The ampules have a shelf life of only 1 year and may disappear because of the potential for abuse (as “poppers”).
- B. **Sodium nitrite parenteral.** A component of the cyanide antidote package, 300 mg in 10 mL of sterile water (3%), two ampules per kit.
- C. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is two cyanide antidote packages, or equivalent (one package should be kept in the emergency department). Available from Taylor Pharmaceuticals.

► NITROPRUSSIDE

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Nitroprusside is an ultrashort-acting and titratable parenteral hypotensive agent that acts by directly relaxing vascular smooth muscle as a nitric

oxide donor. Both arterial and venous dilation occur; the effect is more marked in patients with hypertension. A small increase in heart rate may be observed in hypertensive patients. Intravenous administration produces nearly immediate onset of action, with a duration of effect of 1–10 minutes. Resistance may occur with high renin activity. Nitroprusside is rapidly metabolized, with a serum half-life of about 1–2 minutes. Cyanide is produced during metabolism and is converted to the less toxic thiocyanate. Thiocyanate has a half-life of 2–3 days and accumulates in patients with renal insufficiency.

II. Indications

- A. Rapid control of severe hypertension (eg, in patients with stimulant intoxication or monoamine oxidase inhibitor toxicity).
- B. Arterial vasodilation in patients with ergot-induced peripheral arterial spasm.

III. Contraindications

- A. Compensatory hypertension, for example, in patients with increased intracranial pressure (eg, hemorrhage or mass lesion) or in patients with coarctation of the aorta. If nitroprusside is required in such patients, use with extreme caution.
- B. Use with caution in patients with hepatic insufficiency, because cyanide metabolism may be impaired.

IV. Adverse effects

- A. Nausea, vomiting, headache, and sweating may be caused by excessively rapid lowering of the blood pressure.
- B. **Cyanide toxicity**, manifested by altered mental status and metabolic (lactic) acidosis, may occur with rapid high-dose infusion (≥ 10 – 15 mcg/kg/min) for periods of 1 hour or longer. Patients with depleted thiosulfate stores (eg, malnourished) may have elevated cyanide levels at lower infusion rates. Continuous intravenous infusion of hydroxocobalamin, 25 mg/h (see p 453; note caution with preservative), or thiosulfate (p 505) has been used to limit cyanide toxicity. If severe cyanide toxicity occurs, discontinue the nitroprusside infusion and consider antidotal doses of thiosulfate and sodium nitrite (p 476) or high-dose hydroxocobalamin (p 453; note concentrated form not available in the United States).
- C. **Thiocyanate intoxication**, manifested by disorientation, delirium, muscle twitching, and psychosis, may occur with prolonged high-dose nitroprusside infusions (usually ≥ 3 mcg/kg/min for 48 hours or longer), particularly in patients with renal insufficiency (may occur at rates as low as 1 mcg/kg/min). Thiocyanate production is also enhanced by co-administration of sodium thiosulfate. Monitor thiocyanate levels if the nitroprusside infusion lasts more than 1–2 days; toxicity is associated with thiocyanate levels of 50 mg/L or greater. Usually treat with lowering infusion rate or discontinuing use of nitroprusside. Thiocyanate is effectively removed by hemodialysis.
- D. Rebound hypertension may be observed after sudden discontinuance.
- E. **Use in pregnancy.** FDA category C (indeterminate; see p 405). It may cross the placenta, and it may affect uterine blood flow; however, it has been used successfully in pregnant women.
- V. **Drug or laboratory interactions.** A hypotensive effect is potentiated by other antihypertensive agents and inhalational anesthetics.
- VI. **Dosage and method of administration.**
 - A. Use only in an emergency or intensive care setting with the capability of frequent or continuous blood pressure monitoring.
 - B. Dissolve 50 mg of sodium nitroprusside in 3 mL of 5% dextrose; then dilute this solution in 250, 500, or 1000 mL of 5% dextrose to achieve a concentration of 200, 100, or 50 mcg/mL, respectively. Protect the solution from light to avoid photodegradation (as evidenced by a color change) by covering the bottle and tubing with paper or aluminum foil.
 - C. Start with an intravenous infusion rate of 0.3 mcg/kg/min with a controlled infusion device, and titrate to desired effect. The average dose is 3 mcg/kg/min in children and adults (range, 0.5–10 mcg/kg/min).

1. The maximum rate should not exceed 10 mcg/kg/min to avoid risk of acute cyanide toxicity. If there is no response after 10 minutes at the maximum rate, discontinue the infusion and use an alternate vasodilator (eg, phentolamine; see p 487).
2. Sodium thiosulfate (see p 505) has been added in a ratio of 10 mg thiosulfate to 1 mg nitroprusside to reduce or prevent cyanide toxicity.

VII. Formulations

- A. **Parenteral.** Nitroprusside sodium (Nitropress and others), 50 mg of lyophilized powder for reconstitution in 2- and 5-mL vials.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 24 vials.

► NOREPINEPHRINE

Neal L. Benowitz, MD

- I. **Pharmacology.** Norepinephrine is an endogenous catecholamine that stimulates mainly alpha-adrenergic receptors. It is used primarily as a vasopressor to increase systemic vascular resistance and venous return to the heart. Norepinephrine is also a weak beta-1-adrenergic receptor agonist, and it may increase heart rate and cardiac contractility in patients with shock. Norepinephrine is not effective orally and is erratically absorbed after subcutaneous injection. After intravenous administration, the onset of action is nearly immediate, and the duration of effect is 1–2 minutes after the infusion is discontinued.
- II. **Indications.** Norepinephrine is used to increase blood pressure and cardiac output in patients with shock caused by venodilation or low systemic vascular resistance, or both. Hypovolemia, depressed myocardial contractility, hypothermia, and electrolyte imbalance should be corrected first or concurrently.
- III. **Contraindications**
 - A. Uncorrected hypovolemia.
 - B. Norepinephrine is relatively contraindicated in patients with organic heart disease, peripheral arterial occlusive vascular disease with thrombosis, or ergot poisoning (see p 189).
- IV. **Adverse effects**
 - A. Severe hypertension, which may result in intracranial hemorrhage, pulmonary edema, or myocardial necrosis.
 - B. Aggravation of tissue ischemia, resulting in gangrene.
 - C. Tissue necrosis after extravasation.
 - D. Anxiety, restlessness, tremor, and headache.
 - E. Anaphylaxis induced by sulfite preservatives in sensitive patients. Use with extreme caution in patients with known hypersensitivity to sulfite preservatives.
 - F. Use with caution in patients intoxicated by chloral hydrate or halogenated or aromatic hydrocarbon solvents or anesthetics.
 - G. **Use in pregnancy.** This drug crosses the placenta, and it can cause placental ischemia and reduce uterine contractions.
- V. **Drug or laboratory interactions**
 - A. Enhanced pressor response may occur in the presence of cocaine and cyclic antidepressants, owing to inhibition of neuronal reuptake.
 - B. Enhanced pressor response may occur in patients taking monoamine oxidase inhibitors, owing to inhibition of neuronal metabolic degradation.
 - C. Alpha- and beta-blocking agents may antagonize the adrenergic effects of norepinephrine.
 - D. Anticholinergic drugs may block reflex bradycardia, which normally occurs in response to norepinephrine-induced hypertension, enhancing the hypertensive response.

- E. Chloral hydrate overdose and cyclopropane and halogenated or aromatic hydrocarbon solvents and anesthetics may enhance myocardial sensitivity to arrhythmogenic effects of norepinephrine.

VI. Dosage and method of administration

- A. **Caution: Avoid extravasation.** The intravenous infusion must be free flowing, and the infused vein should be observed frequently for signs of infiltration (pallor, coldness, or induration).

1. If extravasation occurs, immediately infiltrate the affected area with phen-tolamine (see p 487), 5–10 mg in 10–15 mL of normal saline (children, 0.1–0.2 mg/kg; maximum 10 mg) via a fine (25- to 27-gauge) hypodermic needle; improvement is evidenced by hyperemia and return to normal temperature.
2. Alternately, topical application of nitroglycerin paste and infiltration of terbutaline have been reported successful.

- B. **Intravenous infusion.** Begin at 4–8 mcg/min (children, 1–2 mcg/min or 0.1 mcg/kg/min) and increase as needed every 5–10 minutes.

VII. Formulations.

Norepinephrine bitartrate is rapidly oxidized on exposure to air; it must be kept in its airtight ampule until immediately before use. If the solution appears brown or contains a precipitate, do not use it. The stock solution must be diluted in 5% dextrose or 5% dextrose-saline for infusion; usually, a 4-mg ampule is added to 1 L of fluid to provide 4 mcg/mL of solution.

- A. **Parenteral.** Norepinephrine bitartrate (Levophed), 1 mg/mL, 4-mL ampule. Contains sodium bisulfite as a preservative.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is five ampules.

► OCTREOTIDE

Thomas E. Kearney, PharmD

I. Pharmacology

- A. Octreotide is a synthetic polypeptide and a long-acting analog of somatostatin. It significantly antagonizes pancreatic insulin release and is useful for the management of poisonings from drug-induced endogenous secretion of insulin-, oral sulfonyleurea-, and quinine-induced hyperinsulinemic and hypoglycemic poisonings.
- B. Octreotide also suppresses pancreatic function, gastric acid secretion, and biliary and gastrointestinal tract motility.
- C. As a polypeptide, it is bioavailable only by parenteral administration (intravenously or subcutaneously). Approximately 30% of octreotide is excreted unchanged in the urine, and it has an elimination half-life of 1.7 hours. Its half-life may be increased in patients with renal dysfunction and in the elderly.

- II. **Indications.** Oral sulfonyleurea hypoglycemic overdose (see p 93) and quinine-induced hypoglycemia (p 326) when serum glucose concentrations cannot be maintained by an intravenous 5% dextrose infusion. It may also be considered a first-line agent with dextrose since it can reduce glucose requirements and prevent rebound hypoglycemia in patients with sulfonyleurea poisoning. This agent is preferred over diazoxide (p 433). It is uncertain whether octreotide has a role with exogenous insulin poisoning and has a theoretical disadvantage of blocking counterregulatory reactions (prevents glucagon and growth hormone secretion) to hypoglycemia.

- III. **Contraindications.** Hypersensitivity to the drug (anaphylactic shock has occurred).

- IV. Adverse effects.** In general, the drug is well tolerated. Patients may experience pain or burning at the injection site. For the most part, the adverse effect profile is based on long-term therapy for other disease states.
- A.** The suppressive effects on the biliary tract may lead to significant gallbladder disease (cholelithiasis) and pancreatitis.
 - B.** Gastrointestinal effects (diarrhea, nausea, discomfort) may occur in 5–10% of users. Headache, dizziness, and fatigue have also been observed.
 - C.** Cardiac effects may include bradycardia, conduction abnormalities (QT prolongation), hypertension, and exacerbation of congestive heart failure.
 - D. Use in pregnancy.** FDA category B. Not likely to cause harm with short-term therapy (see p 405).
- V. Drug or laboratory interactions**
- A.** Octreotide may inhibit the absorption of dietary fats and cyclosporine.
 - B.** The drug depresses vitamin B₁₂ levels and can lead to abnormal Schilling's test results.
- VI. Dosage and method of administration**
- A. Oral sulfonylurea overdose.** Give 50–100 mcg (children: 4–5 mcg/kg/day divided every 6 hours) by subcutaneous or intravenous injection once or every 6 to 12 hours as needed (some sulfonylurea poisonings may require days of therapy). Infusions up to 125 mcg/h have been used (see note below). May need to monitor for recurrent hypoglycemia for 24 hours after termination of octreotide therapy.
 - B. Quinine-induced hypoglycemia.** A dose of 50 mcg/h has been used in adult patients with malaria.
 - C.** Subcutaneous injection sites should be rotated.
 - D.** For IV administration, dilute in 50 mL normal saline or 5% dextrose and infuse over 15–30 min. Alternately, the dose may be given IV push over 3 min.
 - E. Note:** Optimal dosage regimen is not known. For other indications, daily dosages up to 1500 mcg are utilized (120 mg has been infused over 8 hours without severe adverse effects).
- VII. Formulations**
- A. Parenteral.** Octreotide acetate (Sandostatin): 0.05, 0.1, and 0.5 mg/mL in 1-mL ampules; 0.2 and 1 mg/mL in 5-mL multidose vials.
 - B.** The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is two (1-mL) ampules (0.1 mg/mL) or one (5-mL) multidose vial (0.2 mg/mL).

► ONDANSETRON

Judith A. Alsop, PharmD

- I. Pharmacology.** Ondansetron is a selective serotonin 5-HT₃ receptor antagonist with powerful antiemetic activity, both centrally at the chemoreceptor trigger zone and peripherally at vagal nerve terminals. The onset is about 30 minutes after an intravenous dose and 60–90 minutes after an oral dose. The drug is extensively metabolized in the liver. The elimination half-life is 3–5.5 hours, increasing to as long as 20 hours in patients with severe liver disease.
- II. Indications.** Ondansetron is used to treat intractable nausea and vomiting, particularly when the ability to administer activated charcoal or antidotal therapy (eg, *N*-acetylcysteine) is compromised.
- III. Contraindications.** Known hypersensitivity to the drug.
- IV. Adverse effects**
 - A.** Anxiety, headache, drowsiness, fatigue, fever, and dizziness.
 - B.** Extrapyramidal reactions may occur.
 - C.** Diarrhea and constipation are both reported.

- D. Seizures, hypoxia (rare).
- E. **Use in pregnancy.** FDA category B. Not likely to cause harm when used as short-term therapy.
- V. **Drug or laboratory interactions**
 - A. Extrapyramidal reactions are more likely in patients who are also taking haloperidol or other central dopamine-blocking drugs.
 - B. Anticholinergic agents may inhibit bowel motility.
 - C. Increased liver transaminases have been reported.
- VI. **Dosage and method of administration.** Give 8 mg (adults) or 0.15 mg/kg IV in 50 mL normal saline or 5% dextrose. This may be repeated twice at 4-hour intervals. *Alternate high-dose therapy:* 32 mg (adults) in 50 mL saline or dextrose administered over 15 minutes. (Do not repeat this dose.)
 - A. Ondansetron is most effective when given at least 30 minutes before its antiemetic properties are needed.
 - B. Do not exceed a total daily dose of 8 mg in patients with severe liver disease.
 - C. Ondansetron does not require dilution and can be given by direct intravenous injection over a period of at least 30 seconds, preferably 2–3 minutes.
 - D. Intramuscular use is not recommended.
- VII. **Formulations**
 - A. **Parenteral.** Ondansetron hydrochloride (Zofran): 2 mg/mL in 2-mL single-dose vials and 20-mL multidose vials. Also available as 32 mg in a 50-mL premixed container.
 - B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 32 mg.

► OXYGEN AND HYPERBARIC OXYGEN

Kent R. Olson, MD

- I. **Pharmacology.** Oxygen is a necessary oxidant to drive biochemical reactions. Room air contains 21% oxygen. Hyperbaric oxygen (100% oxygen delivered to the patient in a pressurized chamber at 2–3 atmospheres of pressure) may be beneficial for patients with severe carbon monoxide (CO) poisoning. It can hasten the reversal of CO binding to hemoglobin and intracellular myoglobin, can provide oxygen independent of hemoglobin, and may have protective actions reducing postischemic brain damage. Randomized controlled studies have reported conflicting outcomes with HBO treatment, but there appears to be at least a marginal benefit in preventing subtle neuropsychiatric sequelae.
- II. **Indications**
 - A. Supplemental oxygen is indicated when normal oxygenation is impaired because of pulmonary injury, which may result from aspiration (chemical pneumonitis) or inhalation of toxic gases. The PO_2 should be maintained at 70–80 mm Hg or higher if possible.
 - B. Supplemental oxygen is usually given empirically to patients with altered mental status or suspected hypoxemia.
 - C. Oxygen (100%) is indicated for patients with carbon monoxide poisoning, to increase the conversion of carboxyhemoglobin and carboxymyoglobin to hemoglobin and myoglobin, and to increase oxygen saturation of the plasma and subsequent delivery to tissues.
 - D. Hyperbaric oxygen (HBO) may be beneficial for patients with severe carbon monoxide poisoning, although the clinical evidence is mixed. Potential indications include: history of loss of consciousness; metabolic acidosis, age over 50 years, pregnancy, carboxyhemoglobin level greater than 25%, and cerebellar dysfunction (eg, ataxia).

E. HBO has also been advocated for treatment of poisoning by carbon tetrachloride, cyanide, and hydrogen sulfide, and for severe methemoglobinemia, but the experimental and clinical evidence is scanty.

III. Contraindications

- A. In **paraquat** poisoning, oxygen may contribute to lung injury. In fact, slightly *hypoxic* environments (10–12% oxygen) have been advocated to reduce the risk of pulmonary fibrosis from paraquat.
- B. Relative contraindications to hyperbaric oxygen therapy include a history of recent middle ear or thoracic surgery, untreated pneumothorax, seizure disorder, or severe sinusitis.

IV. Adverse effects. **Caution:** Oxygen is extremely flammable.

- A. Prolonged, high concentrations of oxygen are associated with pulmonary alveolar tissue damage. In general, the fraction of inspired oxygen (FIO₂) should not be maintained at greater than 80% for more than 24 hours.
- B. Oxygen therapy may increase the risk of retrolental fibroplasia in neonates.
- C. Administration of high oxygen concentrations to patients with severe chronic obstructive pulmonary disease and chronic carbon dioxide retention who are dependent on hypoxemia to provide a drive to breathe may result in respiratory arrest.
- D. Hyperbaric oxygen treatment can cause hyperoxic seizures, aural trauma (ruptured tympanic membrane), and acute anxiety. Seizures are more likely at higher atmospheric pressures (eg, 3 atm or greater).
- E. Oxygen may potentiate toxicity via enhanced generation of free radicals with some chemotherapeutic agents (eg, bleomycin, adriamycin, and daunorubicin).
- D. **Use in pregnancy.** No known adverse effects.

V. Drug or laboratory interactions. None known.

VI. Dosage and method of administration

- A. **Supplemental oxygen.** Provide supplemental oxygen to maintain a PO₂ of at least 70–80 mm Hg. If a PO₂ greater than 50 mm Hg cannot be maintained with an FIO₂ of at least 60%, consider positive end-expiratory pressure or continuous positive airway pressure.
- B. **Carbon monoxide poisoning.** Provide 100% oxygen by tight-fitting mask or via endotracheal tube. Consider **hyperbaric oxygen therapy** if the patient has serious poisoning (see Indications, above) and the patient can be treated within 6 hours of the exposure. Consult with a poison center ([800] 222-1222) or hyperbaric specialist to determine the location of the nearest HBO facility. Usually, three HBO treatments at 2.5–3 atm are recommended over a 24-hour period.

VII. Formulations

- A. **Nasal cannula.** See Table III–11.
- B. **Ventimask.** Provides variable inspired oxygen concentrations from 24 to 40%.
- C. **Non-rebreathing reservoir mask.** Provides 60–90% inspired oxygen concentrations.

TABLE III-11. AMOUNT OF OXYGEN PROVIDED BY NASAL CANNULA

Flow Rate (L/min)	Approximate Inspired Oxygen Concentration (%)
1	24
2	28
5	40

- D. Hyperbaric oxygen.** One hundred percent oxygen can be delivered at a pressure of 2–3 atm.

► **PENICILLAMINE**

Thomas E. Kearney, PharmD

- I. Pharmacology.** Penicillamine is a derivative of penicillin that has no antimicrobial activity but effectively chelates some heavy metals such as lead, mercury, and copper. It has been used as adjunctive therapy after initial treatment with calcium EDTA (see p 440) or BAL (dimercaprol; p 413), although its use has largely been replaced by the oral chelator succimer (DMSA, p 501) because of its poor safety profile. Penicillamine is well absorbed orally, and the penicillamine-metal complex is eliminated in the urine. No parenteral form is available.

II. Indications

- A.** Penicillamine may be used to treat heavy metal poisoning caused by lead (if patient is intolerant to succimer, then penicillamine may be used alone for minor intoxication or as adjunctive therapy after calcium EDTA or BAL in moderate to severe intoxication), mercury (after initial BAL therapy and if intolerant of succimer), and copper (succimer may be an alternative for mild to moderate poisoning).
- B.** For lead or mercury poisoning, oral succimer (see p 501) is preferable, as it may result in greater metal excretion with fewer adverse effects.

III. Contraindications

- A.** Penicillin allergy is a contraindication (penicillamine products may be contaminated with penicillin).
- B.** Renal insufficiency is a relative contraindication because the complex is eliminated only through the urine.
- C.** Concomitant administration with other hematopoietic-depressant drugs (eg, gold salts, immunosuppressants, antimalarial agents, and phenylbutazone) is not recommended.
- D.** Cadmium poisoning. It may increase renal levels of cadmium and potential for nephrotoxicity.

IV. Adverse effects

- A.** Hypersensitivity reactions: rash, pruritus, drug fever, hematuria, antinuclear antibodies, and proteinuria.
- B.** Leukopenia, thrombocytopenia, hemolytic anemia, aplastic anemia, and agranulocytosis.
- C.** Hepatitis and pancreatitis.
- D.** Anorexia, nausea, vomiting, epigastric pain, and impairment of taste.
- E.** The requirement for pyridoxine is increased, and the patient may require daily supplementation (see p 499).
- F. Use in pregnancy.** Birth defects have been associated with its use during pregnancy. No assigned FDA category (see p 405).

V. Drug or laboratory interactions

- A.** Penicillamine may potentiate the hematopoietic-depressant effects of drugs such as gold salts, immunosuppressants, antimalarial agents, and phenylbutazone.
- B.** Several drugs (eg, antacids and ferrous sulfate) and food can substantially reduce gastrointestinal absorption of penicillamine.
- C.** Penicillamine may produce a false-positive test for ketones in the urine.

VI. Dosage and method of administration

- A.** Penicillamine should be taken on an empty stomach, at least 1 hour before or 3 hours after meals and at bedtime.
- B.** The usual dose is 20–30 mg/kg/day, administered in three or four divided doses. The usual starting dose in adults is 250 mg four times daily. Initiating

treatment at 25% of this dose and gradually increasing to the full dose over 2–3 weeks may minimize adverse reactions. Maximum adult daily dose is 2 g. In children with mild to moderate lead poisoning, a lower dose, 15 mg/kg/day, has been shown to maintain efficacy at lowering blood levels and minimizing adverse effects.

- C. Weekly measurement of urinary and blood concentrations of the intoxicating metal is indicated to assess the need for continued therapy. Treatment for as long as 3 months has been tolerated.

VII. Formulations. Note: Although the chemical derivative *N*-acetylpenicillamine may demonstrate better central nervous system and peripheral nerve penetration, it is not currently available in the United States.

- A. **Oral.** Penicillamine (Cuprimine, Depen), 125- and 250-mg capsules; 250-mg tablets.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 1500 mg.

► PENTOBARBITAL

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Pentobarbital is a short-acting barbiturate with anticonvulsant as well as sedative-hypnotic properties. It is used as a third-line drug in the treatment of status epilepticus. It may also reduce intracranial pressure in patients with cerebral edema by inducing vasoconstriction. After intravenous administration of a single dose, the onset of effect occurs within about 1 minute and lasts about 15 minutes. Pentobarbital demonstrates a biphasic elimination pattern; the half-life of the initial phase is 4 hours, and the terminal phase half-life is 35–50 hours. Effects are prolonged after termination of a continuous infusion.

II. Indications

- A. Pentobarbital is used for the management of status epilepticus that is unresponsive to conventional anticonvulsant therapy (eg, diazepam, phenytoin, or phenobarbital). If the use of pentobarbital for seizure control is considered, consultation with a neurologist is recommended.
- B. It is used to manage elevated intracranial pressure, in conjunction with other agents.
- C. It may be used therapeutically or diagnostically for patients with suspected alcohol or sedative-hypnotic drug withdrawal syndrome.

III. Contraindications

- A. Known sensitivity to the drug.
- B. Manifest or latent porphyria.

IV. Adverse effects

- A. Central nervous system depression, coma, and respiratory arrest may occur, especially with rapid bolus or excessive doses.
- B. Hypotension may result, especially with rapid intravenous infusion.
- C. Laryngospasm and bronchospasm have been reported after rapid intravenous injection, although the mechanism is unknown.
- D. **Use in pregnancy.** FDA category D (possible fetal risk). Pentobarbital readily crosses the placenta, and chronic use may cause hemorrhagic disease of the newborn (owing to vitamin K deficiency) or neonatal dependency and withdrawal syndrome. However, these potential effects do not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A. Pentobarbital has additive central nervous system and respiratory depression effects with other barbiturates, as well as sedative and opioid drugs.
- B. Hepatic enzyme induction is generally not encountered with acute pentobarbital overdose, although it may occur within 24–48 hours.

- C. Clearance may be enhanced by hemoperfusion, requiring supplemental doses during the procedure.

VI. Dosage and method of administration

- A. **Intermittent intravenous bolus.** Give 100 mg IV slowly over at least 2 minutes; repeat as needed at 2-minute intervals, to a maximum dose of 300–500 mg (children, 1–3 mg/kg IV, repeated as needed to a maximum total of 5–6 mg/kg or 150–200 mg).
- B. **Continuous intravenous infusion.** Administer a loading dose of 5–6 mg/kg IV over 1 hour (not to exceed 50 mg/min; children, 1 mg/kg/min), followed by maintenance infusion of 0.5–3 mg/kg/h titrated to the desired effect. For treatment of status epilepticus, use loading dose of 5–15 mg/kg given by IV infusion over 1 to 2 hours, monitor blood pressure (vasopressor support may be required; eg, dopamine) and provide respiratory support, and follow with maintenance infusion. Electroencephalographic achievement of burst suppression usually occurs with a serum pentobarbital concentration of 25–40 mcg/mL.
- C. **Oral.** The oral regimen for treatment of barbiturate or other sedative-drug withdrawal syndrome is administration of 200 mg orally, repeated every hour until signs of mild intoxication appear (eg, slurred speech, drowsiness, or nystagmus). Most patients respond to 600 mg or less. Repeat the total initial dose every 6 hours as needed. Phenobarbital is an alternative (see below).

VII. Formulations

- A. **Parenteral.** Pentobarbital sodium (Nembutal and others), 50 mg/mL in 1- and 2-mL tubes and vials, and 20- and 50-mL vials.
- B. **Oral.** Capsules (50 and 100 mg) and suppositories (30, 60, 120, and 200 mg). Also available as an elixir.
- C. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is two vials, 50 mL each, or equivalent.

► PHENOBARBITAL

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Phenobarbital is a barbiturate commonly used as an anticonvulsant. Because of the delay in onset of the therapeutic effect of phenobarbital, diazepam (see p 415) is usually the initial agent for parenteral anticonvulsant therapy. After an oral dose of phenobarbital, peak brain concentrations are achieved within 10–15 hours. Onset of effect after intravenous administration is usually within 5 minutes, although peak effects may take up to 30 minutes. Therapeutic plasma levels are 15–35 mg/L. The drug is eliminated by metabolism and renal excretion, and the elimination half-life is 48–100 hours.

II. Indications

- A. Control of tonic-clonic seizures and status epilepticus, generally as a second- or third-line agent after diazepam or phenytoin have been tried. **Note:** For treatment of drug-induced seizures, especially seizures caused by theophylline, phenobarbital is often tried before phenytoin.
- B. Management of withdrawal from ethanol and other sedative-hypnotic drugs.

III. Contraindications

- A. Known sensitivity to barbiturates.
- B. Manifest or latent porphyria.

IV. Adverse effects

- A. Central nervous system depression, coma, and respiratory arrest may result, especially with rapid bolus or excessive doses.
- B. Hypotension may result from rapid intravenous administration. This can be prevented by limiting the rate of administration to less than 50 mg/min (children, 1 mg/kg/min).

C. Use in pregnancy. FDA category D (possible fetal risk). Phenobarbital readily crosses the placenta, and chronic use may cause hemorrhagic disease of the newborn (owing to vitamin K deficiency) or neonatal dependency and withdrawal syndrome. However, these potential effects do not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A.** Phenobarbital has additive central nervous system and respiratory depression effects with other sedative drugs.
- B.** Hepatic enzyme induction with chronic use, although this is **not** encountered with acute phenobarbital dosing.
- C.** Extracorporeal removal techniques (eg, hemodialysis, hemoperfusion, and repeat-dose activated charcoal; see p 54) may enhance the clearance of phenobarbital, possibly requiring supplemental dosing to maintain therapeutic levels.

VI. Dosage and method of administration

- A. Parenteral.** Administer slowly intravenously (rate ≤ 50 mg/min; children, ≤ 1 mg/kg/min) until seizures are controlled or the loading dose of 10–15 mg/kg is achieved. For status epilepticus, give 15–20 mg/kg IV over 10–15 minutes and not to exceed 100 mg/minute (children have required as much as 30 mg/kg in the first 24 hours to treat status epilepticus). Slow the infusion rate if hypotension develops. Intermittent infusions of 2 mg/kg every 5–15 minutes may diminish the risk of respiratory depression or hypotension. For alcohol withdrawal seizures, initial dose of 260 mg, then 130 mg every 30 minutes until signs of mild intoxication (see below).
 - 1. If intravenous access is not immediately available, phenobarbital may be given intramuscularly; the initial dose in adults and children is 3–5 mg/kg IM.
 - 2. It may also be given by the intraosseous route.
- B. Oral.** For treatment of barbiturate or sedative drug withdrawal, give 60–120 mg orally and repeat every hour until signs of mild intoxication appear (eg, slurred speech, drowsiness, or nystagmus).

VII. Formulations

- A. Parenteral.** Phenobarbital sodium (Luminal and others), 30, 60, 65, and 130 mg/mL in 1-mL tubex syringes, vials, and ampules.
- B. Oral.** 15-, 16-, 16.2-, 30-, 60-, 90-, and 100-mg tablets; also elixir (15 and 20 mg/mL).
- C.** The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 16 ampules (130 mg each) or equivalent.

► **PHENTOLAMINE**

Thomas E. Kearney, PharmD

- I. Pharmacology.** Phentolamine is a competitive presynaptic and postsynaptic alpha-adrenergic receptor blocker that produces peripheral vasodilation. By acting on both venous and arterial vessels, it decreases total peripheral resistance and venous return. It may also stimulate beta-adrenergic receptors, causing cardiac stimulation. Phentolamine has a rapid onset of action (usually 2 minutes) and short duration of effect (approximately 15–20 minutes).

II. Indications

- A.** Hypertensive crisis associated with phenylpropanolamine or stimulant drug overdose (eg, amphetamines, cocaine, or ephedrine).
- B.** Hypertensive crisis resulting from interaction between monoamine oxidase inhibitors and tyramine or other sympathomimetic amines.
- C.** Hypertensive crisis associated with sudden withdrawal of sympatholytic antihypertensive drugs (eg, clonidine).

- D. Extravasation of vasoconstrictive agents (eg, epinephrine, norepinephrine, or dopamine).
- III. **Contraindications.** Use with extreme caution in patients with intracranial hemorrhage or ischemic stroke; excessive lowering of blood pressure may aggravate brain injury.
- IV. **Adverse effects**
- A. Hypotension and tachycardia may occur from excessive doses.
- B. Anginal chest pain and cardiac arrhythmias may occur.
- C. Slow intravenous infusion (≤ 0.3 mg/min) may result in transient increased blood pressure caused by stimulation of beta-adrenergic receptors.
- D. **Use in pregnancy.** No assigned FDA category. However, this does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).
- V. **Drug or laboratory interactions.** Additive or synergistic effects may occur with other antihypertensive agents, especially other alpha-adrenergic antagonists (eg, prazosin, terazosin, or yohimbine).
- VI. **Dosage and method of administration**
- A. **Parenteral.** Give 1–5 mg IV (children, 0.02–0.1 mg/kg) as a bolus; repeat at 5- to 10-minute intervals as needed to lower blood pressure to a desired level (usually ≤ 100 mm Hg diastolic in adults and 80 mm Hg diastolic in children, but may vary depending on the clinical situation).
- B. **Catecholamine extravasation.** Infiltrate 5–10 mg in 10–15 mL of normal saline (children, 0.1–0.2 mg/kg; maximum 10 mg) into an affected area with a fine (25- to 27-gauge) hypodermic needle; improvement is evidenced by hyperemia and return to normal temperature.
- VII. **Formulations**
- A. **Parenteral.** Phentolamine mesylate (Regitine, others), 5 mg in 1- and 2-mL vials.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 20 vials.

► PHENYTOIN AND FOSPHENYTOIN

Grant D. Lackey, PharmD, PhD

- I. **Pharmacology.** The neuronal membrane-stabilizing actions of phenytoin make this a popular drug for sustained control of acute and chronic seizure disorders and a useful drug for certain cardiac arrhythmias. Because of the relatively slow onset of anticonvulsant action, phenytoin is usually administered after diazepam. At serum concentrations considered therapeutic for seizure control, phenytoin acts similarly to lidocaine to reduce ventricular premature depolarization and suppress ventricular tachycardia. After intravenous administration, peak therapeutic effects are attained within 1 hour. The therapeutic serum concentration for seizure control is 10–20 mg/L. Elimination is nonlinear, with an apparent half-life averaging 22 hours. **Fosphenytoin**, a prodrug of phenytoin for intravenous use, is converted to phenytoin after injection, with a conversion half-life of 8–32 minutes.
- II. **Indications**
- A. Control of generalized tonic-clonic seizures or status epilepticus. However, benzodiazepines (see p 415) and phenobarbital (p 486) are generally more effective for treating drug-induced seizures.
- B. Control of cardiac arrhythmias, particularly those associated with digitalis intoxication.
- III. **Contraindications.** Known hypersensitivity to phenytoin or other hydantoins.
- IV. **Adverse effects**
- A. Rapid intravenous phenytoin administration (≥ 50 mg/min in adults or 1 mg/kg/min in children) may produce hypotension, atrioventricular block, and

cardiovascular collapse, probably owing to the propylene glycol diluent. Fosphenytoin is readily soluble and does not contain propylene glycol. It can be given intravenously or intramuscularly.

- B. Extravasation of phenytoin may result in local tissue necrosis and sloughing.
- C. Drowsiness, ataxia, nystagmus, and nausea may occur.
- D. **Use in pregnancy.** No assigned FDA category. Congenital malformations (fetal hydantoin syndrome) and hemorrhagic disease of the newborn have occurred with chronic use. However, this does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions.

- A. The various drug interactions associated with chronic phenytoin dosing (ie, accelerated metabolism of other drugs) are not applicable to its acute emergency use.
- B. Extracorporeal removal methods (eg, hemoperfusion and repeat-dose activated charcoal) will enhance phenytoin clearance. Supplemental dosing may be required during such procedures to maintain therapeutic levels.

VI. Dosage and method of administration

A. Parenteral

- 1. **Phenytoin.** Administer a loading dose of 15–20 mg/kg IV slowly at a rate not to exceed 50 mg/min (or 1 mg/kg/min in children). It may be diluted in 50–150 mL of normal saline with use of an in-line filter. Phenytoin has been administered via the intraosseous route in children. Do **not** administer by the intramuscular route.
- 2. **Fosphenytoin.** Dosage is based on the phenytoin equivalent: 750 mg of fosphenytoin is equivalent to 500 mg of phenytoin. (For example, a loading dose of 1 g phenytoin would require a dose of 1.5 g fosphenytoin.) Dilute twofold to tenfold in 5% dextrose or normal saline and administer no faster than 225 mg/min.

- B. **Maintenance oral phenytoin dose.** Give 5 mg/kg/day as a single oral dose of capsules or twice daily for other dosage forms and in children. Monitor serum phenytoin levels.

VII. Formulations

- A. **Parenteral.** Phenytoin sodium, 50 mg/mL, 2- and 5-mL ampules and vials. Fosphenytoin sodium (Cerebyx), 150 mg (equivalent to 100 mg phenytoin) in 2-mL vials or 750 mg (equivalent to 500 mg phenytoin) in 10-mL vials.
- B. **Oral.** Phenytoin sodium (Dilantin and others), 30- and 50-mg chewable tablets, and a 100-mg capsule.
- C. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is six vials (50 mg/mL, 5 mL each) or equivalent.

► PHYSOSTIGMINE AND NEOSTIGMINE

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Physostigmine and neostigmine are carbamates and reversible inhibitors of acetylcholinesterase, the enzyme that degrades acetylcholine. They increase concentrations of acetylcholine, causing stimulation of both muscarinic and nicotinic receptors. The tertiary amine structure of physostigmine allows it to penetrate the blood-brain barrier and exert central cholinergic effects as well. Neostigmine, a quaternary ammonium compound, is unable to penetrate the CNS. Owing to cholinergic stimulation of the brainstem's reticular activating system, physostigmine has nonspecific analeptic (arousal) effects. After parenteral administration of physostigmine, the onset of action is within 3–8 minutes and the duration of effect is usually 30–90 minutes. The elimination half-life is 15–40 minutes. Neostigmine has a slower onset of 7–11 minutes and longer duration of effect of 60–120 minutes.

II. Indications

- A. Physostigmine is used for the management of severe anticholinergic syndrome (agitated delirium, urinary retention, severe sinus tachycardia, or hyperthermia with absent sweating) from antimuscarinic agents (eg, benzotropine, atropine, jimson weed or [*Datura*], diphenhydramine). See p 84 for discussion of anticholinergic toxicity. There are case reports of use with GHB, baclofen, and olanzapine intoxications, but its safety and efficacy are uncertain with these poisonings.
- B. Physostigmine is sometimes used diagnostically to differentiate functional psychosis from anticholinergic delirium.
- C. Neostigmine is used primarily to reverse the effect of nondepolarizing neuromuscular blocking agents.

III. Contraindications

- A. Physostigmine should **not** be used as an antidote for cyclic antidepressant overdose because it may worsen cardiac conduction disturbances, cause bradyarrhythmias or asystole, and aggravate or precipitate seizures.
- B. Do **not** use physostigmine with concurrent use of depolarizing neuromuscular blockers (eg, succinylcholine).
- C. Known hypersensitivity to agent or preservative (eg, benzyl alcohol).

IV. Adverse effects

- A. Bradycardia, heart block, and asystole.
- B. Seizures (particularly with rapid administration or excessive dose of physostigmine).
- C. Nausea, vomiting, hypersalivation, and diarrhea.
- D. Bronchorrhea and bronchospasm.
- E. Fasciculations and muscle weakness.
- F. **Use in pregnancy.** FDA category C (see p 405). Transient weakness has been noted in neonates whose mothers were treated with physostigmine for myasthenia gravis.

V. Drug or laboratory interactions

- A. May potentiate agents metabolized by the cholinesterase enzyme (eg, depolarizing neuromuscular blocking agents—succinylcholine, cocaine, esmolol), cholinesterase inhibitors (eg, organophosphate and carbamate insecticides), and other cholinergic agents (eg, pilocarpine).
- B. They may inhibit or reverse the actions of nondepolarizing neuromuscular blocking agents (eg, pancuronium, vecuronium, etc). Neostigmine is used therapeutically for this purpose.
- C. They may have additive depressant effects on cardiac conduction in patients with cyclic antidepressant, beta-adrenergic antagonist, and calcium antagonist overdoses.
- D. Physostigmine, through its nonspecific analeptic effects, may induce arousal in patients with GHB, opioid, benzodiazepine, or sedative-hypnotic intoxication.

VI. Dosage and method of administration

- A. **Physostigmine.** Parenteral: 0.5–2 mg slow (≤ 1 mg/min as adverse effects may be related to rapid administration) IV push (children, 0.02 mg/kg and given ≤ 0.5 mg/min) while a cardiac monitor is used to monitor the patient; repeat as needed every 10–30 minutes. Usual adult total dose is 4 mg. Atropine (see p 412) should be kept nearby to reverse excessive muscarinic stimulation and given at 1/2 the physostigmine dose (adults: 1–4 mg; children: 1 mg). Do **not** administer physostigmine intramuscularly or as a continuous intravenous infusion.
- B. **Neostigmine.** Parenteral: 0.5–2 mg slow IV push (children: 0.025–0.08 mg/kg/dose) and repeat as required (total dose rarely exceeds 5 mg). Premedicate with glycopyrrolate (0.2 mg per mg of neostigmine; usual adult dose 0.2–0.6 mg; child 0.004–0.02 mg/kg) or atropine (0.4 mg per mg of neostigmine; usual adult dose 0.6–1.2 mg; child 0.01–0.04 mg/kg) several

minutes before or simultaneously with neostigmine to prevent muscarinic effects (bradycardia, secretions).

VII. Formulations

- A. **Parenteral.** Physostigmine salicylate (Antilirium), 1 mg/mL in 1-mL syringes and 2-mL vials (contains benzyl alcohol and bisulfite). Neostigmine methylsulfate (Prostigmine, others), 1:1000, 1:2000, 1:4000 in 1- and 10-mL ampules and vials (contain parabens).
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 10 ampules (2 mL each) for physostigmine and one 10-mL vial of 1:2000 or equivalent for neostigmine.

► POTASSIUM

Judith A. Alsop, PharmD

- I. **Pharmacology.** Potassium is the primary intracellular cation, which is essential for maintenance of acid-base balance, intracellular tonicity, transmission of nerve impulses, contraction of cardiac, skeletal, and smooth muscle, and maintenance of normal renal function (and ability to alkalinize urine). Potassium also acts as an activator in many enzyme reactions and participates in many physiological processes such as carbohydrate metabolism, protein synthesis, and gastric secretion. Potassium is critical in regulating nerve conduction and muscle contraction, especially in the heart. A variety of toxins cause alterations in serum potassium levels (see Table I-27, p 38).

II. Indications

- A. For treatment or prevention of hypokalemia (see p 37).
- B. Supplement to bicarbonate therapy (see p 419) for alkalinization of urine.

III. Contraindications

- A. Potassium should be administered cautiously in patients with renal impairment or impairment of renal excretion of potassium (ACE inhibitor toxicity and hypoaldosteronism, potassium-sparing diuretics) to avoid the potential for serious hyperkalemia.
- B. Potassium should be administered cautiously in patients with impairment of intracellular transport of potassium (due to inhibition of Na-K ATPase pump with cardiac glycosides or inhibition of beta-adrenergic transport with beta blockers). Administration of potassium may lead to large incremental rises in serum levels.
- C. Potassium should be administered cautiously in patients with intracellular spillage of potassium (rhabdomyolysis, hemolysis).

IV. Adverse effects

- A. Nausea, vomiting, abdominal pain, and diarrhea with oral administration.
- B. **Parenteral administration.** **Note:** DO NOT use undiluted injectable potassium preparations: direct injection can be lethal if given too rapidly; pain at the injection site and phlebitis may occur, especially during infusion of solutions containing greater than 30 mEq/L.
- C. Hyperkalemia is the most serious adverse reaction (see p 37).
- D. **Use in pregnancy.** FDA category C (indeterminate) (see p 405).

V. Drug or laboratory interactions

- A. Drug interactions, see Contraindications, above.
- B. Numerous IV incompatibilities (mannitol, diazepam, dobutamine, nitroprusside, phenytoin, penicillin G, calcium, phosphate, sulfate).
- C. Serum potassium levels may be fictitiously elevated if the blood sample is hemolyzed.

VI. Dosage and method of administration (adults and children)

- A. The dose is variable and depends on the serum potassium level and severity of symptoms. The normal serum potassium level is 3.5–5 mEq/L. For parenteral administration, potassium must be diluted (see Adverse Effects, above).

- B. The usual daily adult maintenance dose is 40–80 mEq. The usual daily pediatric maintenance dose is 2–3 mEq/kg or 40 mEq/m².
- C. Potassium depletion resulting in a 1-mEq/L decrease in serum potassium may require 100–200 mEq for replacement to restore body stores. This replacement requirement will be offset with changes or corrections in intracellular transport (reversal of methylxanthine or beta-adrenergic agonist toxicity).
- D. For a serum potassium of 2.5 mEq/L or greater, the maximum infusion rate of potassium in adults is 10 mEq/h, maximum concentration is 40 mEq/L, and maximum dose is 200 mEq per 24 hours. Do not exceed 30 mEq/L for IV use in pediatric patients. Adjust volume of fluid to body size of patient.
- E. For a serum potassium of less than 2.0 mEq/L, the maximum infusion rate of potassium in adults is 40 mEq/h, maximum concentration is 80 mEq/L, and maximum dose is 400 mEq per 24 hours.
- F. Continuous cardiac monitoring is essential during administration of IV potassium.

VII. Formulations

- A. Potassium acetate injection: 2 mEq/mL in 20-, 50-, and 100-mL vials; 4 mEq/mL in 50-mL vials.
- B. Potassium chloride for injection concentrate: 2 mEq/mL in 250 and 500 mL; 10 mEq in 5-, 10-, 50-, and 100-mL vials and 5-mL additive syringes; 20 mEq in 10- and 20-mL vials, 10-mL additive syringes, and 10-mL ampules; 30 mEq in 15-, 20-, 30-, and 100-mL vials and 20-mL additive syringes; 40 mEq in 20-, 30-, 50-, and 100-mL vials, 20-mL ampules, and 20-mL additive syringes; 60 mEq in 30-mL vials; and 90 mEq in 30-mL vials.
- C. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 500 mEq.

► PRALIDOXIME (2-PAM) AND OTHER OXIMES

Richard J. Geller, MD, MPH

- I. **Pharmacology.** Oximes reverse acetylcholinesterase (AChE) inhibition by reactivating the phosphorylated cholinesterase enzyme and protecting the enzyme from further inhibition. While this effect is most pronounced with organophosphate pesticides, positive clinical results have been seen with carbamate insecticides that have nicotinic toxicity. The clinical effects of oximes are most apparent at nicotinic receptors, with reversal of skeletal muscle weakness and muscle fasciculations. Their impact on muscarinic symptoms (salivation, sweating, bradycardia, and bronchorrhea) is significantly less pronounced than that of the antimuscarinic agents atropine and glycopyrrrolate, with which oximes are invariably administered (see p 412).
- A. Pralidoxime chloride (2-PAM) is the only oxime currently approved for use in the United States. Oximes differ in their effectiveness against specific agents, dose, and side-effect profile. In the United Kingdom, the methanesulfonate salt of pralidoxime, P2S, is used. In other European countries and South Africa, TMB4 and obidoxime (Toxogonin) are employed. 2-PAM methiodide is used in Japan.
- B. Oximes are effective when given before the enzyme has been irreversibly bound ("aged") by the organophosphate, although they may have additional modes of action. The rate of aging varies considerably with each organophosphorus compound. For dimethylphosphorylated AChE (eg, from dichlorvos, malathion poisoning), the aging half-life is approximately 3.7 hours, while for diethylphosphorylated AChE (eg, from diazinon or parathion poisoning), the aging half-life is approximately 33 hours. For some chemical warfare agents, aging may occur in several minutes (soman-phosphorylated AChE aging half-life is about 2–6 minutes). However, late therapy with

2-PAM is appropriate (even several days after exposure), especially in patients poisoned with diethylating compounds and by fat-soluble compounds (eg, fenthion, demeton, or sulfoton) that can be released from tissue stores over days, causing continuous or recurrent intoxication.

- C. "Nerve" agents prepared as chemical warfare weapons, such as sarin, soman, tabun, and VX, are mechanistically similar to AChE-inhibiting insecticides. However, they are far more potent and only responsive to certain oximes. Pralidoxime is not effective against tabun, for example, but trime-doxime (TMB4) may be. Current oxime research seeking agents with broader activity against nerve agents is evaluating the H oximes HLO- 7 and HI- 6.
- D. Inadequate dosing of 2-PAM may be linked to the "intermediate syndrome," which is characterized by prolonged muscle weakness.
- E. Peak plasma concentrations are reached within 5–15 minutes after intra-venous 2-PAM administration. Pralidoxime is eliminated by renal excretion and hepatic metabolism, with a half-life of 0.8–2.7 hours.

II. Indications

- A. Oximes are used to treat poisoning caused by cholinesterase inhibitor insecticides and nerve agents, ie, organophosphates, mixtures of organophosphorus and carbamate insecticides, or pure carbamate insecticide intoxication with nicotinic-associated symptoms. Because of its low toxicity, possible ineffectiveness if treatment is delayed until after the cholinesterase enzyme has aged, ability to reverse nicotinic as well as muscarinic effects, and ability to reduce atropine requirements, pralidoxime should be used early and empirically for suspected cholinesterase inhibitor poisoning.
- B. With carbamate poisoning, cholinesterase inhibition spontaneously resolves without "aging" of the enzyme. As a result, many references state that pralidoxime is not needed for carbamate poisoning. However, spontaneous reversal of enzyme inhibition may take up to 30 hours, and case reports suggest that pralidoxime is effective in human carbamate poisoning. Data suggesting increased toxicity of pralidoxime in carbaryl (Sevin) poisoning are based on limited animal studies and the results are not generalizable to humans.

III. Contraindications

- A. Use in patients with myasthenia gravis may precipitate a myasthenic crisis.
- B. Use with caution and in reduced doses in patients with renal impairment.

IV. Adverse effects

- A. Nausea, headache, dizziness, drowsiness, diplopia, and hyperventilation may occur.
- B. Rapid intravenous administration may result in tachycardia, laryngospasm, muscle rigidity, and transient neuromuscular blockade. Hypertension, reversible with either drug cessation or by administration of phentolamine, 5 mg IV, is also ascribed to rapid infusion.
- C. **Use in pregnancy.** FDA category C (indeterminate). This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A. Symptoms of atropinization may occur more quickly when atropine (or glycopyrrolate) and pralidoxime are administered concurrently.
- B. RBC cholinesterase (ChE) activity is more readily reactivated by pralidoxime compared with plasma ChE.

VI. Dosage and method of administration.

For pralidoxime, the intravenous route is preferred. Intramuscular or subcutaneous injection is possible when the intravenous route is not immediately available.

- A. **Initial dose.** Give 1–2 g (children, 25–50 mg/kg up to 1 g) as a continuous intravenous infusion in 100 mL of saline (1–2 mL/kg) over 15–30 minutes. Repeat the initial dose after 1 hour if muscle weakness or fasciculations are not relieved. Several grams may be required in some cases.
- B. **Immediate field treatment of nerve agent poisoning** is accomplished with intramuscular 2-PAM. Dose is 600 mg IM for mild to moderate symptoms and

up to 1800 mg for severe poisonings. The Mark I autoinjector kit contains 600 mg 2-PAM and 2 mg atropine and is designed for self-administration

- C. Maintenance infusion.** Because of the short half-life of 2-PAM and the longer duration of many organophosphorus compounds, toxicity frequently recurs, requiring repeated doses.

1. Discrete intermittent boluses may result in wide fluctuation in serum levels and erratic clinical effects. Therefore, after the initial dose it is preferable to give 2-PAM as a continuous intravenous infusion in a 1% solution (1 g in 100 mL saline) at a rate of 200–500 mg/h (children, 5–10 mg/kg/h) and titrate to the desired clinical response.
2. Despite earlier recommendations that 2-PAM should be given for only 24 hours, therapy may need to be continued for several days, particularly when long-acting, lipid-soluble organophosphates are involved. Gradually reduce the dose and carefully observe the patient for signs of recurrent muscle weakness or other signs of toxicity.

3. **Note:** 2-PAM may accumulate in patients with renal insufficiency.

VII. Formulations

- A. Parenteral.** Pralidoxime chloride (2-PAM, Protopam), 1 g with 20 mL sterile water.
- B.** The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 12 vials. **Note:** In agricultural areas or in urbanized regions preparing for possible accidental or terrorist release of a large amount of cholinesterase inhibitor agent, much larger stockpiling may be appropriate. In the wake of the terrorist attack in September 2001, the US government partnered with cities and counties in an initiative known as the Metropolitan Medical Response System (MMRS). Supplies of Mark I autoinjector kits, 1-g vials of pralidoxime chloride, 20-mL vials of atropine (0.4 mg/mL), and diazepam were purchased for local use with federal grant money. Larger regional federal antidote depots were also created.

► PROPOFOL

Richard Lynton, MD

I. Pharmacology

- A.** Propofol (2,6-diisopropylphenol) is a sedative-hypnotic agent in a class of alkyl phenol compounds. It is an oil at room temperature, highly lipid soluble, and administered as an emulsion. Propofol's site of action is at the GABA_A receptor, where it activates the chloride channel. There may also be some action at the glutamate and glycine receptor sites. Propofol is an inhibitor of cytochrome P-450 and may have some antioxidant properties.
- B.** On infusion its effects are seen within less than 3 minutes and peak concentrations are reached in less than 20 minutes.
- C.** It is highly protein bound, with a volume of distribution of 2–5 L/kg after a single infusion, and 25–60 L/kg after a continuous infusion of greater than 7 days. Propofol has a high clearance rate estimated at 1.5–2.2 L/min. This clearance rate exceeds hepatic blood flow and suggests extrahepatic metabolism.
- D.** Propofol is rapidly metabolized in the liver by conjugation to glucuronide and sulfate intermediates that are water soluble and inactive. There is minimal enterohepatic circulation and less than 1% is excreted unchanged.

II. Indications

- A.** Propofol is most useful where the goal of anesthesia or sedation is rapid induction and recovery. It can be used for the induction and maintenance of anesthesia.
- B.** Propofol is useful in the intensive care unit for sedation of mechanically ventilated patients. It may be beneficial for conscious sedation in certain settings.

- C. Propofol may be effective as an adjunct anesthetic agent for refractory alcohol or other sedative-hypnotic withdrawal syndromes and for status epilepticus.
- D. Propofol has been used for treatment of opiate withdrawal.

III. Contraindications

- A. Not approved for pediatric patients less than 3 years of age requiring sedation for mechanical ventilation. Several deaths have been reported where propofol was used in this setting.
- B. It may be contraindicated for patients with seizure disorders (risk of seizures while weaning therapy) and those with underlying hyperlipidemic states.
- C. Hypersensitivity to propofol or additives (sulfites). Allergy to soybean or eggs may be a relative contraindication.

IV. Adverse effects

- A. Pain at the injection site can occur (use larger veins or premedicate with lidocaine).
- B. Rapid infusion rates and anesthetic doses require respiratory support. Avoid rapid bolus doses in elderly due to higher risk of hypotension, bradycardia, apnea, and airway obstruction.
- C. Anesthetic doses may be associated with myoclonus, posturing, and seizure-like movement phenomena (jerking, thrashing). Seizures have been noted when weaning from propofol. Allergic reactions to metabisulfite are possible. Bacterial infections have also been noted.
- D. **Propofol infusion syndrome**, a condition of metabolic (lactic) acidosis, renal failure, rhabdomyolysis, and cardiovascular collapse, has been reported after prolonged high-dose infusion in both pediatric and adult populations.
- E. Acute pancreatitis with single or prolonged use can occur. Hyperlipidemia can also occur after prolonged use.
- F. Though not thought of as a drug of abuse, propofol abuse has been reported.
- G. **Use in pregnancy.** FDA category B. Propofol crosses the placenta and may be associated with neonatal CNS depression (see p 405).

V. Drug or laboratory interactions

- A. Additive effect with other CNS depressants that may result in lower propofol dosage requirements if given concomitantly. Through its inhibition of cytochrome P-450, propofol may increase levels of midazolam, diazepam, and other opiates such as sufentanyl and alfentanyl, causing respiratory depression, bradycardia, and hypotension.
- B. Propofol levels may be increased by lidocaine, bupivacaine, and halothane, producing an increased hypnotic effect.
- C. Concurrent use of succinylcholine and propofol may result in bradycardia.

VI. Dosage and method of administration.

Propofol is currently administered as an intravenous medication only and the dosage must be individualized and titrated.

- A. For induction anesthesia give 1–2.5 mg/kg (slow infusion rate of about 40 mg every 10 seconds). If titrating with intermittent bolus doses (usually 40-mg increments), allow approximately 2 minutes for peak effect. For maintenance anesthesia, the dose should be titrated between 50 and 150 mcg/kg/min (or 3–9 mg/kg/h) and may be supplemented with intermittent bolus doses of 25–50 mg. After initial induction dose, may require higher continuous infusion dose of up to 200 mcg/kg/min (or 12 mg/kg/h) for the first 10–15 minutes.
- B. For sedation purposes, use a lower dosage range of 25–75 mcg/kg/min (or 1.5–4.5 mg/kg/h) or titrate with intermittent bolus doses of 10–20 mg, then maintain with 25–50 mcg/kg/min (or 1.5–3 mg/kg/h).
- C. Pediatric patients may require a higher dose: 2.5–3.5 mg/kg induction dose, followed immediately by 200–300 mcg/kg/min (or 12–18 mg/kg/h) for about 30 minutes, then 125–150 mcg/kg/min (or 7.5–9 mg/kg/h).
- D. For patients older than 60 years of age a lower induction dose of 1–1.5 mg/kg (infuse about 20 mg every 10 seconds) is recommended.

- E. For rapid opiate detoxification, patients are given 2–4 mg/kg (or 6 mg/kg/h with intermittent bolus doses of 0.3–0.5 mg/kg) followed by maintenance of 3.5–6 mg/kg/h (usually for 5–8 hours). This is coupled with a neuromuscular blocker, and an opiate antagonist (naloxone or naltrexone) is administered after anesthesia is achieved.

VII. Formulations

- A. **Parenteral.** Propofol (Diprivan) 1% (10 mg/mL) emulsion in 10% soybean oil with 2.25% glycerol and 1.25% purified egg phospholipid in 20-, 50-, or 100-mL vials and a 50-mL prefilled syringe. Contains disodium EDTA or sodium metabisulfite in the US formulation as preservatives. A 2% (20 mg/mL) emulsion has been formulated to provide the same amount of drug with less lipid concentration, but is not yet approved in the United States. **Note:** Propofol is provided as a ready-to-use preparation, but if dilution is necessary, only use D5W and don't dilute to concentrations less than 2 mg/mL.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 2.5 g (provides anesthesia for a 6-hour interval).

► PROPRANOLOL

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Propranolol is a nonselective beta-adrenergic blocker that acts on beta-1 receptors in the myocardium and beta-2 receptors in the lung, vascular smooth muscle, and kidney. Within the myocardium, propranolol depresses heart rate, conduction velocity, myocardial contractility, and automaticity. Although propranolol is effective orally, for toxicological emergencies it is usually administered by the intravenous route. After intravenous injection, the onset of action is nearly immediate and the duration of effect is 10 minutes to 2 hours, depending on the cumulative dose. The drug is eliminated by hepatic metabolism, with a half-life of about 2–3 hours. Propranolol also has antagonistic properties at the 5-HT_{1A} receptor and has been used to treat serotonin syndrome with mixed success (anecdotal case reports).

II. Indications

- A. To control excessive sinus tachycardia or ventricular arrhythmias caused by catecholamine excess (eg, theophylline or caffeine), sympathomimetic drug intoxication (eg, amphetamines, pseudoephedrine, or cocaine), or excessive myocardial sensitivity (eg, chloral hydrate, freons, or chlorinated and other hydrocarbons).
- B. To control hypertension in patients with excessive beta-1–mediated increases in heart rate and contractility; use in conjunction with a vasodilator (eg, phenolamine) in patients with mixed alpha- and beta-adrenergic hyperstimulation.
- C. To raise the diastolic blood pressure in patients with hypotension caused by excessive beta-2–mediated vasodilation (eg, theophylline or metaproterenol).
- D. May ameliorate or reduce beta-adrenergic–mediated electrolyte and other metabolic abnormalities (eg, hypokalemia, hyperglycemia, or lactic acidosis).
- E. Serotonin syndrome (see p 22).

III. Contraindications

- A. Use with extreme caution in patients with asthma, congestive heart failure, sinus node dysfunction, or other cardiac conduction disease and in those receiving calcium antagonists and other cardiac-depressant drugs.
- B. Do not use as single therapy for hypertension resulting from sympathomimetic overdose. Propranolol produces peripheral vascular beta-blockade, which may abolish beta-2–mediated vasodilation and allow unopposed alpha-mediated vasoconstriction, resulting in paradoxical worsening of hypertension.

IV. Adverse effects

- A. Bradycardia and sinus and atrioventricular block.

- B. Hypotension and congestive heart failure.
- C. Bronchospasm in patients with asthma or bronchospastic chronic obstructive pulmonary disease. **Note:** Propranolol (in *small* intravenous doses) has been used successfully in asthmatic patients overdosed on theophylline or beta-2 agonists, without precipitating bronchospasm.
- D. **Use in pregnancy.** FDA category C (indeterminate). Propranolol may cross the placenta, and neonates delivered within 3 days of administration of this drug may have persistent beta-adrenergic blockade. However, this does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions

- A. Propranolol may allow unopposed alpha-adrenergic stimulation in patients with mixed adrenergic stimulation (eg, epinephrine surge in patients with acute hypoglycemia, pheochromocytoma, or cocaine or amphetamine intoxication), resulting in severe hypertension or end-organ ischemia.
- B. Propranolol has an additive hypotensive effect with other antihypertensive agents.
- C. This drug may potentiate competitive neuromuscular blockers (see p 472).
- D. The drug has additive depressant effects on cardiac conduction and contractility when given with calcium antagonists.
- E. Cimetidine reduces hepatic clearance of propranolol.
- F. Propranolol may worsen vasoconstriction caused by ergot alkaloids.

VI. Dosage and method of administration

- A. **Parenteral.** Give 0.5–3 mg slow IV not to exceed 1 mg/min (children, 0.01–0.1 mg/kg slow IV over 5 minutes; maximum 1 mg/dose) while monitoring heart rate and blood pressure; dose may be repeated as needed after 5–10 minutes. The dose required for complete beta receptor blockade is about 0.2 mg/kg. For serotonin syndrome, give 1 mg IV not to exceed 1 mg/min (children 0.1 mg/kg/dose over 10 min; maximum 1 mg/dose) every 2–5 minutes until a maximum of 5 mg. May repeat at 6- to 8-hour intervals.
- B. **Oral.** Oral dosing may be initiated after the patient is stabilized; the dosage range is about 1–5 mg/kg/day in three or four divided doses for both children and adults. For serotonin syndrome, an adult dose of 20 mg every 8 hours has been used.

VII. Formulations

- A. **Parenteral.** Propranolol hydrochloride (Inderal and others), 1 mg/mL in 1-mL ampules, vials, and prefilled syringes.
- B. **Oral.** Propranolol hydrochloride (Inderal and others), 60-, 80-, 120-, and 160-mg sustained-release capsules; 10-, 20-, 40-, 60-, 80-, and 90-mg tablets; 4-, 8-, and 80-mg/mL oral solution and concentrate.
- C. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 10 ampules or syringes.

► PROTAMINE

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Protamine is a cationic protein obtained from fish sperm that rapidly binds to and inactivates heparin. The onset of action after intravenous administration is nearly immediate (30–60 seconds) and lasts up to 2 hours. It also partially neutralizes low-molecular-weight heparins (LMWHs) and can act as an anticoagulant itself by inhibiting thromboplastin.

II. Indications

- A. Protamine is used for the reversal of the anticoagulant effect of heparin when an excessively large dose has been inadvertently administered. Protamine is generally not needed for treatment of bleeding during standard heparin therapy because discontinuance of the heparin infusion is generally sufficient.

- B. Protamine may be used for reversal of regional anticoagulation in the hemodialysis circuit in cases in which anticoagulation of the patient would be contraindicated (ie, active gastrointestinal or central nervous system bleeding).

III. Contraindications

- A. Do not give protamine to patients with known sensitivity to the drug. Diabetic patients who have used protamine insulin may be at the greatest risk for hypersensitivity reactions.
- B. Protamine reconstituted with benzyl alcohol should not be used in neonates because of suspected toxicity from the alcohol.

IV. Adverse effects

- A. Rapid intravenous administration is associated with hypotension, bradycardia, and anaphylactoid reactions. Have epinephrine (see p 442), diphenhydramine (p 436), and cimetidine or another H_2 blocker (p 428) ready. Reaction may be prevented by avoiding high infusion rates of > 5 mg/min.
- B. A rebound effect caused by heparin may occur within 8 hours of protamine administration.
- C. Excess doses may lead to anticoagulation and risk of bleeding.
- D. **Use in pregnancy.** FDA category C (indeterminate). Maternal hypersensitivity reaction or hypotension could result in placental ischemia. However, this does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

- V. **Drug or laboratory interactions.** No known drug interactions, other than the reversal of the effect of heparin.

VI. Dosage and method of administration

- A. Administer protamine by slow intravenous injection, over at least 1–3 minutes, not to exceed 50 mg in a 10-minute period.
- B. The dose of protamine depends on the total dose and time since administration of heparin.
 - 1. If immediately after heparin administration, give 1–1.5 mg of protamine for each 100 units of heparin.
 - 2. If 30–60 minutes after heparin administration, give only 0.5–0.75 mg of protamine for each 100 units of heparin.
 - 3. If 2 hours or more after heparin administration, give only 0.25–0.375 mg of protamine for each 100 units of heparin.
 - 4. If heparin was being administered by constant infusion, give 25–50 mg of protamine.
- C. If the patient is overdosed with an unknown quantity of heparin, then give an empiric dose of 25–50 mg over 15 minutes (to minimize hypotension) and determine the activated partial thromboplastin time (aPTT) after 5–15 minutes and for up to 2–8 hours to determine need for additional doses.
- D. **For an overdose of a low-molecular-weight heparin (LMWH):**
 - 1. **Dalteparin or tinzaparin.** Give 1 mg of protamine for every 100 anti-factor Xa international units of dalteparin and tinzaparin.
 - 2. **Enoxaparin.** Give 1 mg of protamine for each 1 mg of enoxaparin.
 - 3. If the overdose amount is unknown, consider an empiric dose of 25–50 mg given over 15 minutes. The anti-Xa:IIa factor ratios vary for LMWH products and if high, as with a LMW heparinoid (eg, danaparoid), protamine may be ineffective. Anti-factor Xa activity levels and aPTT values are usually not completely reversed, but the hemorrhagic effect may be neutralized. LMWHs have longer half-lives (4–6 hours) and accumulate with renal insufficiency; therefore, coagulopathies may persist and protamine should be considered even several hours after the overdose.

VII. Formulations

- A. **Parenteral.** Protamine sulfate, 50 mg in 5-mL ampules and vials or 250 mg in 25-mL ampules and vials.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is four ampules or one vial.

► PRUSSIAN BLUE

Michael A. Miller, MD

- I. **Pharmacology.** Prussian blue (ferric hexacyanoferrate) has been used to treat radioactive cesium and thallium poisonings. It functions by means of ion exchange. Oral intake of Prussian blue is thought to bind thallium and cesium in the gut as they undergo enterohepatic recirculation, leading to increased fecal excretion.
- II. **Indications**
 - A. Radioactive cesium exposure.
 - B. Thallium poisoning.
- III. **Contraindications.** There are no absolute contraindications. The efficacy of the agent relies upon a functioning GI tract; thus, ileus may preclude its use and effectiveness.
- IV. **Adverse effects**
 - A. Very large doses may lead to slight constipation.
 - B. While further experience is being gained with this agent, adverse effects appear quite rare.
- V. **Drug or laboratory interactions**
 - A. No major interactions.
 - B. May decrease absorption of tetracycline.
- VI. **Dosage and method of administration.** Typical doses are 1 g orally TID. Dosages ranging from 2 to 20 g orally divided TID have been used depending upon the level of exposure. Duration of therapy may range from days to weeks. The decision must be tailored to each given case.
- VII. **Formulations**
 - A. Oral formulation: 0.5-g gelatin capsule from HEYL GmbH in Germany.
 - B. **Suggested minimum stocking level.** Not relevant—available only through the Radiation Emergency Assistance Center (REAC/TS), which should be contacted for information on obtaining Prussian blue and its recommended dosing ([865] 576-3131, on the Internet at www.ornl.gov/reacts). In a case of suspected nuclear weapon detonation, the Joint Nuclear Accident Coordinating Center ([505] 845-4667/[703] 325-2102) should also be contacted.

► PYRIDOXINE (VITAMIN B₆)

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Pyridoxine (vitamin B₆) is a water-soluble B-complex vitamin that acts as a cofactor in many enzymatic reactions. Overdose involving isoniazid or other monomethylhydrazines (eg, *Gyromitra* mushrooms) may cause seizures by interfering with pyridoxine utilization in the brain, and pyridoxine given in high doses can rapidly control these seizures and may hasten consciousness. It can also correct the lactic acidosis secondary to isoniazid-induced impaired lactate metabolism. In ethylene glycol intoxication, pyridoxine may enhance metabolic conversion of the toxic metabolite glyoxylic acid to the nontoxic product glycine. Pyridoxine is well absorbed orally but is usually given intravenously for urgent uses. The biologic half-life is about 15–20 days.
- II. **Indications**
 - A. Acute management of seizures caused by intoxication with isoniazid (see p 233), hydrazine, *Gyromitra* mushrooms (p 271), or possibly cycloserine. Pyridoxine may act synergistically with diazepam (p 415).
 - B. Adjunct to therapy for ethylene glycol intoxication.
 - C. May improve dyskinesias induced by levodopa.
- III. **Contraindications.** Use caution in patients with known sensitivity to pyridoxine or preservative.

IV. Adverse effects

- A. Usually no adverse effects are noted from acute dosing of pyridoxine.
- B. Chronic excessive doses may result in peripheral neuropathy (see p 30).
- C. **Use in pregnancy.** FDA category A (see p 405). However, chronic excessive use in pregnancy has resulted in pyridoxine withdrawal seizures in neonates.

V. Drug or laboratory interactions.

No adverse interactions are associated with acute dosing.

VI. Dosage and method of administration

- A. **Isoniazid poisoning.** Give 1 g of pyridoxine intravenously for each gram of isoniazid known to have been ingested (as much as 52 g has been administered and tolerated). Dilute in 50 mL dextrose or saline and give over 5 minutes (rate of 1 g/min). If the ingested amount is unknown, administer 4–5 g IV empirically and repeat every 5–20 minutes as needed.
- B. **Monomethylhydrazine poisoning.** Give 25 mg/kg IV; repeat as necessary.
- C. **Ethylene glycol poisoning.** Give 50 mg IV or IM every 6 hours until intoxication is resolved.
- D. **Cycloserine poisoning.** A dosage of 300 mg/day has been recommended.

VII. Formulations

- A. **Parenteral.** Pyridoxine hydrochloride (Beesix, others), 100 mg/mL (10% solution) in 10- and 30-mL vials (contains benzyl alcohol).
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 20 g (20 vials, 10 mL each, or equivalent).

► SILIBININ OR MILK THISTLE (*SILYBUM MARIANUM*)

Christine A. Haller, MD

- I. **Pharmacology.** Extracts of the milk thistle plant have been used since ancient times to treat a variety of liver and gallbladder diseases, including cholestasis, jaundice, cirrhosis, acute and chronic hepatitis, and primary malignancies, and to protect the liver against toxin-induced injury. The extract of the ripe seeds and leaves contains 70–80% of the active flavonoid silymarin, which is comprised chiefly of silybin A and B, known collectively as silibinin or silybinin. The hypothesized mechanism of action of silymarin, supported by in vitro and animal studies, is twofold: alteration of hepatocyte cell membrane permeability preventing toxin penetration, and increased ribosomal protein synthesis promoting hepatocyte regeneration. Silymarin is also reported to have antifibrotic, anti-inflammatory, and antioxidant activity. One study showed preservation of hepatic glutathione stores in rats exposed to high levels of acetaminophen. Competitive inhibition of *Amanita phalloides* toxin receptor binding has also been demonstrated. There is preliminary evidence that milk thistle constituents may also protect against the nephrotoxic effects of drugs such as acetaminophen, cisplatin, and vincristine. The efficacy of milk thistle in treatment and prophylaxis of toxin-induced liver injury in humans has not been clearly established.
- II. **Indications.** Unproven but possibly effective as adjuvant therapy in cases of acute hepatic injury due to *Amanita phalloides* mushroom ingestion, acetaminophen toxicity, and potentially other chemical and drug-induced liver diseases. Silymarin is not available as a pharmaceutical drug in the United States, but milk thistle extracts can be purchased for oral use as “dietary supplements.” However, these products may not be comparable in quality and consistency to European prescription preparations.
- III. **Contraindications.** None reported.
- IV. **Adverse effects** are few and generally mild.
 - A. Nausea, diarrhea, abdominal fullness or pain, flatulence, and anorexia may occur.

- B. Milk thistle is a member of the *Asteraceae* (daisy) family, and can cause an allergic reaction in ragweed-sensitive individuals, including rash, urticaria, pruritus, and anaphylaxis.
- C. **Use in pregnancy.** FDA category B. Insufficient reliable information is available (see p 405).
- V. **Drug or laboratory interactions.** There is some evidence that milk thistle may inhibit CYP2C9 and CYP3A4 enzyme activity, which might theoretically increase plasma levels of drugs metabolized by these enzymes, including amitriptyline, diazepam, clozapine, warfarin, mirtazapine, ketoconazole, and others. Drug interactions with milk thistle extract have not been reported in humans.
- VI. **Dosage and method of administration**
 - A. Oral doses used in published studies have ranged from 240 to 800 mg/day of standardized silymarin. A typical dose used for toxic hepatitis is 420 mg/day in one or two oral doses.
 - B. Intravenous dosing for *Amanita phalloides* mushroom poisoning is 20–50 mg/kg over 24 hours divided into four infusions. Each intravenous dose is administered over 2 hours. Parenteral milk thistle extract is not available in the United States.
- VII. **Formulations**
 - A. **Oral.** In the United States, milk thistle extract is available only as a nonprescription dietary supplement (eg, Thisilyn). Oral pharmaceutical formulations available in Europe include Legalon (standardized to contain 70% silymarin) and Silibide (isolated silibinin complexed with phosphatidylcholine). Because silymarin is poorly water soluble, milk thistle tea is not considered an effective preparation.
 - B. **Parenteral.** A water-soluble derivative of silybinin is used parenterally in Europe for cases of *Amanita phalloides* mushroom poisoning. Intravenous formulations of milk thistle extract are not available in the United States.

► SUCCIMER (DMSA)

Michael J Kosnett, MD, MPH

I. Pharmacology

- A. Succimer (meso-2,3-dimercaptosuccinic acid [DMSA]) is a chelating agent used in the treatment of intoxication from several heavy metals. A water-soluble analog of BAL (dimercaprol; see p 413), succimer enhances the urinary excretion of lead and mercury. Its effect on elimination of the endogenous minerals calcium, iron, and magnesium is insignificant. Minor increases in zinc and copper excretion may occur. In an animal model, oral succimer was not associated with a significant increase in gastrointestinal absorption of lead; the effect of oral succimer on gastrointestinal absorption of mercury and arsenic is not known.
- B. Following oral administration, peak blood concentrations occur in approximately 3 hours. Distribution is predominantly extracellular, and in the blood it is extensively bound (>90%) to plasma proteins. Succimer is eliminated primarily in the urine, where 80–90% appears as mixed disulfides, mainly 2:1 or 1:1 cysteine-succimer adducts. Studies suggest that these adducts, rather than the parent drug, may be responsible for metal chelating activity in vivo. The elimination half-life of transformed succimer is approximately 2–4 hours. Renal clearance may be diminished in the setting of pediatric lead intoxication.

II. Indications

- A. Succimer is approved for treatment of **lead** intoxication, where it is associated with increased urinary excretion of the metal and concurrent reversal of

metal-induced enzyme inhibition. Oral succimer is comparable to parenteral calcium EDTA (see p 440) in decreasing blood lead concentrations. Although succimer treatment has been associated with subjective clinical improvement, controlled clinical trials demonstrating therapeutic efficacy have yet to be reported. A recent large, randomized, double-blind, placebo-controlled trial of succimer in children with blood lead concentrations between 25 and 44 mcg/dL found no evidence of benefit on clinical outcome or long-term blood lead reduction.

- B. Succimer is protective against the acute lethal and nephrotoxic effects of **mercuric salts** in animal models, and increases urinary mercury excretion in animals and humans. It may therefore have clinical utility in the treatment of human poisoning by inorganic mercury.
- C. Succimer is protective against acute lethal effects of **arsenic** in animal models and may have potential utility in acute human arsenic poisoning.

III. **Contraindications.** History of allergy to the drug. Because succimer and its transformation products undergo renal elimination, safety and efficacy in patients with severe renal insufficiency are uncertain. There is no available evidence that succimer increases hemodialysis clearance of toxic metals in anuric patients.

IV. Adverse effects

- A. Gastrointestinal disturbances including anorexia, nausea, vomiting, and diarrhea are the most common side effects and occur in less than 10% of patients. There may be a mercaptan-like odor to the urine, which has no clinical significance.
- B. Mild, reversible increases in liver transaminases have been observed in 6–10% of patients.
- C. Rashes, some requiring discontinuation of treatment, have been reported in less than 5% of patients.
- D. Isolated cases of mild to moderate neutropenia have been reported.
- E. Minimal increases (less than twofold) in urinary excretion of zinc and copper have been observed and have minor or no clinical significance.
- F. **Use in pregnancy.** FDA category C (indeterminate). Succimer has produced adverse fetal effects when administered to pregnant animals in amounts one to two orders of magnitude greater than recommended human doses. However, succimer has also diminished the adverse effects of several heavy metals in animal studies. Its effect on human pregnancy has not been determined (see p 405).

V. **Drug or laboratory interactions.** No known interactions. Concurrent administration with other chelating agents has not been adequately studied.

VI. Dosage and method of administration (adults and children)

- A. **Lead poisoning.** Availability in the United States is limited to an oral formulation (100-mg capsules) officially approved by the FDA for use in children with blood lead levels ≥ 45 mcg/dL. However, DMSA can also lower lead concentrations in adults. **Note:** Administration of DMSA should never be a substitute for removal from lead exposure. In adults, the federal OSHA lead standard requires removal from occupational lead exposure of any worker with a single blood lead concentration in excess of 60 mcg/dL or an average of three successive values in excess of 50 mcg/dL; however, recent data suggest that removal at lower blood lead levels may be warranted. **Prophylactic chelation**, defined as the routine use of chelation to prevent elevated blood lead concentrations or to lower blood lead levels below the standard in asymptomatic workers, **is not permitted**. Consult the local or state health department or OSHA (see Table IV–3, p 525) for more detailed information.
 - 1. Give 10 mg/kg (or 350 mg/m² in children) orally every 8 hours for 5 days, and then give the same dose every 12 hours for 2 weeks.
 - 2. An additional course of treatment may be considered based on posttreatment blood lead levels and on the persistence or recurrence of symptoms. Although blood lead levels may decline by more than 50% during treatment, patients with high body lead burdens may experience rebound to

within 20% of pretreatment levels as bone stores equilibrate with tissue levels. Check blood lead levels 1 and 7–21 days postchelation to assess the extent of rebound and/or the possibility of reexposure.

3. Experience with oral succimer for severe lead intoxications (ie, lead encephalopathy) is very limited. In such cases, consideration should be given to parenteral therapy with calcium EDTA (see p 440).

B. Mercury and arsenic poisoning

1. Intoxication by inorganic mercury compounds and arsenic compounds may result in severe gastroenteritis and shock. In such circumstances, the capacity of the gut to absorb orally administered succimer may be severely impaired, and use of an available parenteral agent such as unithiol (see p 506) or BAL (p 413) may be preferable.
2. Give 10 mg/kg (or 350 mg/m²) orally every 8 hours for 5 days, and then give the same dose every 12 hours for 2 weeks. Extending the duration of treatment in the presence of continuing symptoms or high levels of urinary metal excretion should be considered, but is of undetermined value.

VII. Formulations

- A. Oral.** Succimer, *meso*-2,3-dimercaptosuccinic acid, DMSA (Chemet), 100-mg capsules in bottles of 100.
- B. Parenteral.** A parenteral form of DMSA (sodium 2,3-dimercaptosuccinate), infused at a dose of 1–2 g per day, has been in use in the People's Republic of China, but is not available in the United States.
- C.** The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 21 capsules.

► TETANUS TOXOID AND IMMUNE GLOBULIN

John H. Tegzes, VMD

- I. Pharmacology.** Tetanus is caused by tetanospasmin, a protein toxin produced by *Clostridium tetani* (see Tetanus, p 351).
 - A. Tetanus toxoid** uses modified tetanospasmin, which has been made non-toxic but still retains the ability to stimulate the formation of antitoxin. Tetanus toxoid provides active immunization to those with known, complete tetanus immunization histories, as well as to those with either unknown or incomplete histories.
 - B. Human tetanus immune globulin** (antitoxin) provides passive immunity by neutralizing circulating tetanospasmin and unbound toxin in a wound. It does not have an effect on toxin that is already bound to neural tissue, and tetanus antibody does not penetrate the blood-brain barrier.
- II. Indications.** All wound injuries require consideration of tetanus prevention and treatment. This includes animal and insect bites and stings, injections from contaminated hypodermic needles, deep puncture wounds (including high-pressure, injection-type chemical exposures, such as those from paint guns), burns, and crush wounds.
 - A. Tetanus toxoid prophylaxis** (active immunization) is given as a primary series of three doses in childhood. The first and second doses are given 4 to 8 weeks apart, while the third dose is given 6 to 12 months after the second. A booster dose is required every 10 years.
 1. **Unknown or incomplete history** of a previous primary series of three doses: tetanus toxoid is indicated for all wounds, including clean, minor wounds.
 2. **Known complete histories** of a primary series of three doses: tetanus toxoid is indicated for clean, minor wounds if it has been longer than 10 years since the last dose, and for all other wounds if it has been longer than 5 years since the last dose.

- B. Tetanus immune globulin** (passive immunization) is indicated for persons with tetanus. Antitoxin is also indicated as prophylaxis for wounds that are neither clean nor minor in persons who have unknown or incomplete histories of the primary three-dose series of tetanus toxoid.

III. Contraindications

A. Toxoid

1. History of a severe allergic reaction (acute respiratory distress and collapse) after a previous dose of tetanus toxoid.
2. History of encephalopathy within 72 hours of a previous dose of tetanus toxoid.
3. Precautions should be taken in individuals with histories of fever greater than 40.5°C within 48 hours of a previous dose, collapse or shock-like state within 48 hours of a previous dose, or seizures within 3 days of a previous dose.

- B. Antitoxin.** The *equine* tetanus antitoxin is contraindicated in persons who have had previous hypersensitivity or serum sickness reactions to other equine-derived products. Preferably, use the *human* tetanus immune globulin product in all cases, if it is available.

IV. Adverse effects to the toxoid

- A.** Local effects, including pain, erythema, and induration at the injection site. These are usually self-limiting, and do not require therapy.
- B.** Exaggerated local (Arthus-like) reactions. These unusual reactions may present as extensive painful swelling from the shoulder to the elbow. They generally occur in individuals with preexisting very high serum tetanus antitoxin levels.
- C.** Severe systemic reactions such as generalized urticaria, anaphylaxis, or neurologic complications have been reported. A few cases of peripheral neuropathy and Guillain-Barré syndrome have also been reported.
- D. Use in pregnancy.** FDA category C (indeterminate). Tetanus toxoid may be used during pregnancy. Pregnant patients not previously vaccinated should receive the three-dose primary series (see p 405).

V. Drug or laboratory interactions. None.

VI. Dosage and method of administration

A. Tetanus toxoid

1. Adult Td consists of tetanus toxoid, 5 LF U/0.5 mL, and diphtheria toxoid, adsorbed 2 LF U/0.5 mL up to 12.5 LF U/0.5 mL. A 0.5-mL dose is given intramuscularly. Adult Td is used for routine boosters and primary vaccination in persons 7 years old and older. Three doses constitute a primary series of Td. The first two doses are separated by a minimum of 4 weeks, with the third dose given 6–12 months after the second. Boosters are given every 10 years thereafter.
2. In children less than 7 years old, primary tetanus immunization is with tetanus toxoid in combination with diphtheria toxoid and acellular pertussis (DTaP). Pediatric DT (without pertussis) may also be used when there is a contraindication to pertussis vaccine. At least 4 weeks should separate the first and second and the second and third doses. A fourth dose should be given no less than 6 months after the third dose. All doses are 0.5 mL given intramuscularly, and usually contain tetanus toxoid 5 LF U/0.5 mL.

- B. Antitoxin.** Human tetanus immune globulin is given at 3000–5000 units intramuscularly, in divided doses, for the treatment of tetanus in children and adults, with part of the dose infiltrated around the wound. Doses of 250–500 units intramuscularly are given for postexposure prophylaxis.

VII. Formulations

- A. Adult.** Tetanus toxoid 5 LF U/0.5 mL in combination with diphtheria toxoid, adsorbed 2 LF U/0.5 mL, supplied in 0.5-mL single-dose vials; tetanus toxoid 5 LF U/0.5 mL in combination with diphtheria toxoid, adsorbed 6.6 LF U/0.5 mL to 12.5 LF U/0.5 mL, supplied in 5-mL multidose vials.
- B. Pediatric.** Pediatric DT, 0.5-mL single-dose vials, and 5-mL multidose vials; DTaP, containing diphtheria toxoid 6.7 LF U/0.5 mL, tetanus toxoid 5 LF U/0.5 mL, and pertussis vaccine 4 protective units/0.5 mL.

- C. **Human tetanus immune globulin.** Supplied in single-dose vials containing 250 units.
- D. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is a single-dose vial of Td and immune globulin.

► THIAMINE (VITAMIN B₁)

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Thiamine (vitamin B₁) is a water-soluble vitamin that acts as an essential cofactor for various pathways of carbohydrate metabolism. Thiamine also acts as a cofactor in the metabolism of glyoxylic acid (produced in ethylene glycol intoxication). Thiamine deficiency may result in beriberi and Wernicke-Korsakoff syndrome. Thiamine is rapidly absorbed after oral, intramuscular, or intravenous administration. However, parenteral administration is recommended for initial management of thiamine deficiency syndromes.
- II. **Indications**
 - A. Empiric therapy to prevent and treat Wernicke-Korsakoff syndrome in alcoholic or malnourished patients. This also includes any patient presenting with an altered mental status of unknown etiology. Thiamine should be given concurrently with glucose in such patients.
 - B. Adjunctive treatment in patients poisoned with ethylene glycol to possibly enhance the detoxification of glyoxylic acid.
- III. **Contraindications.** Use caution in patients with known sensitivity to thiamine or preservative.
- IV. **Adverse effects**
 - A. Anaphylactoid reactions, vasodilation, hypotension, weakness, and angioedema after rapid intravenous injection. This may be attributable to the vehicle or contaminants of thiamine preparations in the past; rare reaction with new preparations.
 - B. Acute pulmonary edema in patients with beriberi, owing to sudden increase in vascular resistance.
 - C. **Use in pregnancy.** FDA category A for doses up to the recommended daily allowance (RDA) and category C for pharmacologic doses (see p 405).
- V. **Drug or laboratory interactions.** Theoretically, thiamine may enhance the effect of neuromuscular blockers, although the clinical significance is unclear.
- VI. **Dosage and method of administration.** Parenteral, 100 mg (children, 50 mg) slow IV (over 5 minutes) or IM; may repeat every 8 hours at doses of 5–100 mg. For Wernicke's encephalopathy, follow with daily parenteral doses of 50–100 mg until the patient is taking a regular diet. Doses as high as 1 g over the first 12 hours have been given to patients with acute Wernicke-Korsakoff syndrome.
- VII. **Formulations**
 - A. **Parenteral.** Thiamine hydrochloride, 100 mg/mL, in 1-, 2-, 10-, and 30-mL ampules, vials, and prefilled syringes (vials may contain chlorobutanol).
 - B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 1 g (one 10-mL vial or equivalent).

► THIOSULFATE, SODIUM

Susan Kim, PharmD

- I. **Pharmacology.** Sodium thiosulfate is a sulfur donor that promotes the conversion of cyanide to less toxic thiocyanate by the sulfur transferase enzyme rhodanese. Unlike nitrites, thiosulfate is essentially nontoxic and may be given empirically in suspected cyanide poisoning.

II. Indications

- A. May be given alone or in combination with nitrites (see p 476) in patients with acute cyanide poisoning.
- B. Empiric treatment of possible cyanide poisoning associated with smoke inhalation.
- C. Prophylaxis during nitroprusside infusions (see p 477).
- D. Extravasation of mechlorethamine (infiltrate locally; see p 101).
- E. Bromate salt ingestion (unproved).

III. Contraindications. No known contraindications.

IV. Adverse effects

- A. Intravenous infusion may produce burning sensation, muscle cramping and twitching, and nausea and vomiting.
- B. **Use in pregnancy.** FDA category C (indeterminate). This does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

V. Drug or laboratory interactions. Thiosulfate will falsely lower measured cyanide concentrations in several methods.

VI. Dosage and method of administration

- A. **For cyanide poisoning.** Administer 12.5 g (50 mL of 25% solution) IV at 2.5–5 mL/min. The pediatric dose is 400 mg/kg (1.6 mL/kg of 25% solution) up to 50 mL. Half the initial dose may be given after 30–60 minutes if needed.
- B. **For prophylaxis during nitroprusside infusions.** Addition of 10 mg thiosulfate for each mg of nitroprusside in the intravenous solution has been reported to be effective, although physical compatibility data are not available.

VII. Formulations

- A. **Parenteral.** As a component of the cyanide antidote package, thiosulfate sodium, 25% solution, 50 mL. Also available separately in vials and ampules containing 2.5 g/10 mL or 1 g/10 mL.
- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is two cyanide antidote packages (one should be kept in the emergency department). Available from Taylor Pharmaceuticals.

► UNITHIOL (DMPS)

Michael J. Kosnett, MD, MPH

- I. **Pharmacology.** Unithiol (DMPS; 2,3-dimercaptopropanol-sulfonic acid; Dimaval), a dimercapto chelating agent that is a water-soluble analog of BAL (see p 413), is used in the treatment of poisoning by several heavy metals, principally mercury, arsenic, and lead. Available on the official formularies of Russia and former Soviet countries since 1958, and in Germany since 1976, unithiol has also been legally available from compounding pharmacists in the United States since 1999. The drug can be administered orally and parenterally. Oral bioavailability is approximately 50%, with peak blood concentrations occurring in approximately 3.7 hours. It is extensively bound to plasma proteins, mainly albumin. More than 80% of an intravenous dose is excreted in the urine, 10% as unaltered unithiol and 90% as transformed products, predominantly cyclic DMPS sulfides. The elimination half-life for total unithiol is approximately 20 hours. Unithiol and/or its in vivo biotransformation products form complexes with a variety of inorganic and organic metal compounds, increasing excretion of the metal in the urine, and decreasing its concentration in various organs, particularly the kidney. Unlike BAL, unithiol does not redistribute mercury to the brain.

II. Indications

- A. Unithiol has been used primarily in the treatment of intoxication by **mercury, arsenic, and lead**. In animal models, unithiol has averted or reduced acute toxic effects of inorganic mercury salts and inorganic arsenic when administered promptly (minutes to hours) after exposure. Unithiol is associated with a

reduction in tissue levels of mercury, arsenic, and lead in experimental animals, and it increases the excretion of these metals in humans. However, randomized, double-blind, placebo-controlled clinical trials demonstrating therapeutic efficacy in acute or chronic heavy metal poisoning have yet to be reported.

- B. Animal studies and a few case reports suggest that unithiol may have utility in the treatment of poisoning by **bismuth** compounds.

III. Contraindications

- A. History of allergy to the drug.
- B. Because renal excretion is the predominant route of elimination of unithiol and its metal complexes, caution is warranted in administering unithiol to patients with severe renal insufficiency. Use of unithiol as an adjunct to hemodialysis or hemofiltration in patients with anuric renal failure due to mercury salts and bismuth has been reported.

IV. Adverse effects

- A. The German manufacturer (Heyl) notes a low overall incidence (<4%) of adverse side effects.
- B. Self-limited, reversible allergic dermatological reactions, such as exanthems or urticaria, have been the most commonly reported adverse effect. Isolated cases of major allergic reactions, including erythema multiforme and Stevens-Johnson syndrome, have been reported.
- C. Because rapid intravenous administration may be associated with vasodilatation and transient hypotension, intravenous injections of unithiol should be administered slowly, over a 15- to 20-minute interval.
- D. Unithiol increases the urinary excretion of copper and zinc, an effect that is not anticipated to be clinically significant in patients without preexisting deficiency of these trace elements.
- E. **Use in pregnancy.** Unithiol did not exhibit teratogenicity or other developmental toxicity in animal studies. Although protection against the adverse reproductive effects of selected toxic metals has been demonstrated in pregnant animals, there is insufficient clinical experience regarding the use of unithiol in human pregnancy.
- V. **Drug or laboratory interactions.** Aqueous solutions of unithiol for intravenous injection should not be mixed with other drugs or minerals. Oral preparations should not be consumed simultaneously with mineral supplements.
- VI. **Dosage and method of administration.** Unithiol may be administered by oral, intramuscular, or intravenous routes. The intravenous route should be reserved for treatment of severe acute intoxication by inorganic mercury salts or arsenic where compromised gastrointestinal or cardiovascular status may interfere with rapid or efficient absorption from the gastrointestinal tract. In animal models, oral unithiol did not increase the gastrointestinal absorption of mercuric chloride.
 - A. **Severe acute poisoning by inorganic mercury or arsenic.** Administer 3–5 mg/kg every 4 hours by slow intravenous infusion over 20 minutes. If, after several days, the patient's gastrointestinal and cardiovascular status have stabilized, consider changing to oral unithiol, 4–8 mg/kg every 6–8 hours.
 - B. **Symptomatic poisoning by lead (without encephalopathy).** Oral unithiol, 4–8 mg/kg orally every 6–8 hours, may be considered an alternative to succimer (see p 501). **Note:** Parenteral therapy with EDTA (see p 440) is preferable for treatment of severe lead intoxication (lead encephalopathy or lead colic), or for patients with extremely high blood lead concentrations (eg, blood lead >150 mcg/dL).
 - C. Mobilization or "chelation challenge" tests measuring an increase in urinary excretion of mercury and arsenic following a single dose of unithiol have been described, but their diagnostic or prognostic value has not been established.

VII. Formulations

- A. In the United States, compounding pharmacists (including hospital inpatient pharmacies) may obtain bulk quantities of pharmaceutical grade unithiol (eg,

Dimaval) and dispense it as injection solutions for infusion (usually 50 mg/mL in sterile water). Capsules (typically in 100- or 300-mg sizes) may also be prepared as an oral dose form.

- B. The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 2100 mg.

► VITAMIN K₁ (PHYTONADIONE)

Thomas E. Kearney, PharmD

- I. **Pharmacology.** Vitamin K₁ is an essential cofactor in the hepatic synthesis of coagulation factors II, VII, IX, and X. In adequate doses, vitamin K₁ reverses the inhibitory effects of coumarin and indanedione derivatives on the synthesis of these factors. **Note: Vitamin K₃ (menadione) is *not* effective** in reversing excessive anticoagulation caused by these agents. After parenteral vitamin K₁ administration, there is a 6- to 8-hour delay before vitamin K–dependent coagulation factors begin to achieve significant levels, and peak effects are not seen until 1–2 days after initiation of therapy. The duration of effect is 5–10 days. The response to vitamin K₁ is variable and the optimal dosage regimen unknown; it is influenced by the potency and amount of the ingested anticoagulant, vitamin K pharmacokinetics, and the patient's hepatic biosynthetic capability. Fresh frozen plasma or whole blood is indicated for immediate control of serious hemorrhage.

II. Indications

- A. Excessive anticoagulation caused by coumarin and indanedione derivatives, as evidenced by elevated prothrombin time. Vitamin K₁ is **not** indicated for empiric treatment of anticoagulant ingestion, as most cases do not require treatment.
- B. Vitamin K deficiency (eg, malnutrition, malabsorption, or hemorrhagic disease of the newborn) with coagulopathy.
- C. Hypoprothrombinemia resulting from salicylate intoxication.

- III. **Contraindications.** Do not use in patients with known hypersensitivity to vitamin K or preservatives.

IV. Adverse effects

- A. **Black box warning:** Anaphylactoid reactions have been reported after intravenous administration and have been associated with fatalities. Intravenous use should be restricted to true emergencies; the patient must be closely monitored in an intensive care setting.
- B. Intramuscular administration in anticoagulated patients may cause large, painful hematomas. This can be avoided by using oral or subcutaneous routes.
- C. Patients receiving anticoagulants for medical reasons (eg, deep vein thrombosis or prosthetic heart valves) may experience untoward effects from complete reversal of their anticoagulation status. Preferably, such patients should receive small quantities of fresh frozen plasma or extremely small titrated doses (0.5–1 mg) of vitamin K until the prothrombin time is in the desired therapeutic range (eg, 1.5–2 times normal). Adjunctive anticoagulation with heparin may be required until the desired prothrombin time is achieved.
- D. **Use in pregnancy.** FDA category C (indeterminate). Vitamin K₁ crosses the placenta readily. However, this does not preclude its acute, short-term use for a seriously symptomatic patient (see p 405).

- V. **Drug or laboratory interactions.** Empiric use after an acute anticoagulant overdose will delay (for up to several days) the onset of elevation of prothrombin time, which may give a false impression of insignificant ingestion in a case of serious “superwarfarin” overdose (see p 378).

VI. Dosage and method of administration

- A. **Oral.** The usual dose of vitamin K₁ (**not** menadione or vitamin K₃) is 10–50 mg two to four times a day in adults and 5–10 mg (or 0.4 mg/kg/dose) two to

four times a day in children. Recheck the prothrombin time after 48 hours, and increase the dose as needed. **Note:** Very high daily doses (7 mg/kg per day or more) have been required in adults with brodifacoum poisoning; in addition, treatment for several weeks or months may be needed because of the long duration of effect of the “superwarfarin.” Because the only available oral vitamin K₁ formulation is 5 mg, high-dose treatment may require patients to ingest up to 100 pills per day, and long-term compliance with the regimen is often problematic.

- B. Parenteral injection** is an alternate route of administration, but is not likely to result in more rapid reversal of anticoagulant effects, and is associated with potentially serious side effects. If hemorrhage is present, use fresh frozen plasma for rapid replacement of coagulation factors. Subcutaneous administration is preferred over IM injection, although both can cause hematomas. The maximum volume is 5 mL or 50 mg per dose per injection site. The adult dose is 10–25 mg, and that for children is 1–5 mg; this may be repeated in 6–8 hours. Switch to oral therapy as soon as possible. Intravenous administration is rarely used because of the risk of anaphylactoid reaction. The usual dose is 10–25 mg (0.6 mg/kg in children under 12 years), depending on the severity of anticoagulation, diluted in preservative-free dextrose or sodium chloride solution. Give slowly at a rate not to exceed 1 mg/min or 5% of the total dose per minute, whichever is slower.

VII. Formulations. **Note:** Do NOT use menadione (vitamin K₃).

- A. Parenteral.** Phytonadione (AquaMEPHYTON and others), 2 and 10 mg/mL, in 0.5-, 1-, 2.5-, and 5-mL ampules, vials, and prefilled syringes (ampules and vials contain fatty acid derivative and benzyl alcohol).
- B. Oral.** Phytonadione (Mephyton), 5-mg tablets.
- C.** The **suggested minimum stocking level** to treat a 70-kg adult for the first 24 hours is 100 mg (two 5-mL ampules, 10 mg/mL each, or equivalent).

SECTION IV. ENVIRONMENTAL AND OCCUPATIONAL TOXICOLOGY

► EMERGENCY MEDICAL RESPONSE TO HAZARDOUS MATERIALS INCIDENTS

Kent R. Olson, MD, and R. Steven Tharratt, MD

With the constant threat of accidental releases of hazardous materials and the potential use of chemical weapons by terrorists, local emergency response providers must be prepared to handle victims who may be contaminated with chemical substances. Many local jurisdictions have developed hazardous-materials (HazMat) teams, usually composed of fire and paramedical personnel who are trained to identify hazardous situations quickly and to take the lead in organizing a response. Health care providers, such as ambulance personnel, nurses, physicians, and local hospital officials, should participate in emergency response planning and drills with their local HazMat team before a chemical disaster occurs.

- I. **General considerations.** The most important elements of successful medical management of a hazardous-materials incident are as follows:
 - A. Use extreme caution when dealing with unknown or unstable conditions.
 - B. Rapidly assess the potential hazard severity of the substances involved.
 - C. Determine the potential for secondary contamination of downstream personnel and facilities.
 - D. Perform any needed decontamination at the scene **before** victim transport, if possible.
- II. **Organization.** Chemical accidents are managed under the **Incident Command System**. The Incident Commander or Scene Manager is usually the senior representative of the agency having primary traffic investigative authority, but authority may be delegated to a senior fire or health official. The first priorities of the Incident Commander are to secure the area, establish a command post, create hazard zones, and provide for the decontamination and immediate prehospital care of any victims. However, hospitals must be prepared to manage victims who leave the scene before teams arrive and who may arrive at the emergency department unannounced, possibly contaminated, and needing medical attention.
 - A. **Hazard Zones** (Figure IV–1) are determined by the nature of the spilled substance and wind and geographic conditions. In general, the command post and support area are located upwind and uphill from the spill, with sufficient distance to allow rapid escape if conditions change.
 1. The **Exclusion Zone** (also known as the “hot” or “red” zone) is the area immediately adjacent to the chemical incident. This area may be extremely hazardous to persons without appropriate protective equipment. Only properly trained and equipped personnel should enter this zone, and they may require vigorous decontamination when leaving the area.
 2. The **Contamination Reduction Zone** (also known as the “warm” or “yellow” zone) is where victims and rescuers are decontaminated before undergoing further medical assessment and prehospital care. Patients in the Exclusion and Contamination Reduction Zones will generally receive only rudimentary first aid such as cervical spine stabilization and placement on a backboard.
 3. The **Support Zone** (also known as the “cold” or “green” zone) is where the Incident Commander, support teams, press, medical treatment areas, and ambulances are located. It is usually upwind, uphill, and a safe distance from the incident.
 - B. **Medical officer.** A member of the HazMat team should already have been designated to be in charge of health and safety. This person is responsible,

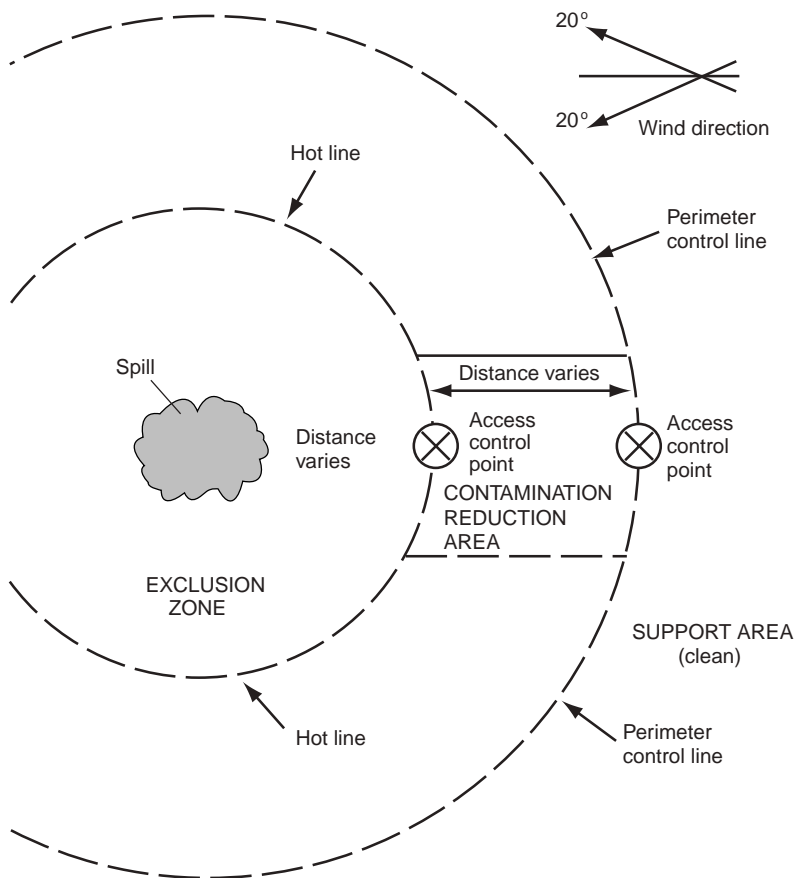

FIGURE IV-1. Control zones at a hazardous-materials incident site.

with help from the technical reference specialist, for determining the nature of the chemicals; the likely severity of their health effects; the need for specialized personal protective gear; the type and degree of decontamination required; and the supervision of triage and prehospital care. In addition, the medical officer, with the site safety officer, supervises the safety of response workers at the emergency site and monitors entry to and exit from the spill site.

III. Assessment of hazard potential. Be prepared to recognize dangerous situations and to respond appropriately. The potential for toxic or other types of injury depends on the chemicals involved, their toxicity, their chemical and physical properties, the conditions of exposure, and the circumstances surrounding their release. Be aware that a substance's reactivity, flammability, explosiveness, or corrosiveness may be a source of greater hazard than its systemic toxicity. Do not depend on your senses for safety, even though sensory input (eg, smell) may give clues about the nature of the hazard.

A. Identify the substances involved. Make inquiries and look for labels, warning placards, or shipping papers.

1. The **National Fire Protection Association (NFPA)** has developed a labeling system for describing chemical hazards which is widely used (Figure IV-2).
 2. The **US Department of Transportation (DOT)** has developed a system of warning placards for vehicles carrying hazardous materials. The DOT placards usually bear a four-digit substance identification code and a single-digit hazard classification code (Figure IV-3). Identification of the substance from the four-digit code can be provided by the regional poison control center, CHEMTREC, or the DOT manual (see B, below).
 3. **Shipping papers**, which may include Material Safety Data Sheets (MSDS), are usually carried by a driver or pilot or may be found in the truck cab or pilot's compartment.
- B. Obtain toxicity information.** Determine the acute health effects and obtain advice on general hazards, decontamination procedures, and medical management of victims. Resources include the following:
1. **Regional poison control centers** ([800] 222-1222). The regional poison control center can provide information on immediate health effects, the need for decontamination or specialized protective gear, and specific treatment, including the use of antidotes. The regional center can also provide consultation with a medical toxicologist.
 2. **CHEMTREC** ([800] 424-9300). Operated by the Chemical Manufacturers' Association, this 24-hour hotline can provide information on the identity and hazardous properties of chemicals and, when appropriate, can put the caller in touch with industry representatives and medical toxicologists.

NATIONAL FIRE PROTECTION ASSOCIATION IDENTIFICATION OF THE FIRE HAZARDS OF MATERIALS

NFPA 704

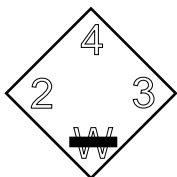

Hazard Signal System

Flammability (Red)

- 4 – Highly flammable and volatile
- 3 – Highly flammable
- 2 – Flammable
- 1 – Low flammability
- 0 – Does not burn

Health hazard (Blue)

- 4 – Extremely hazardous
- 3 – Moderately hazardous
- 2 – Hazardous
- 1 – Slightly hazardous
- 0 – No health hazard

Reactivity (Yellow)

- 4 – Highly explosive, detonates easily
- 3 – Explosive, less readily detonated
- 2 – Violently reactive but does not detonate
- 1 – Not violently reactive
- 0 – Normally stable

Other hazards

– Radioactive

OX – Oxidizer

– Water-reactive

FIGURE IV-2. National Fire Protection Association (NFPA) identification of the hazards of materials. (Modified and reproduced, with permission, from *Fire Protection Guide on Hazardous Materials*, 9th ed. National Fire Protection Association, 1986.) (continued on p 513)

Signal	Identification of Health Hazard Color Code: BLUE	Identification of Flammability Color Code: RED		Identification of Reactivity (Stability) Color Code: YELLOW	
	Type of Possible Injury	Susceptibility of Materials to Burning		Susceptibility to Release of Energy	
	Signal	Signal		Signal	
4	Materials which on very short exposure could cause death or major residual injury even though prompt medical treatment were given.	4	Materials which will rapidly or completely vaporize at atmospheric pressure and normal ambient temperature, or which are readily dispersed in air and which will burn readily.	4	Materials which in themselves are readily capable of detonation or of explosive decomposition or reaction at normal temperatures and pressures.
3	Materials which on short exposure could cause serious temporary or residual injury even though prompt medical treatment were given.	3	Liquids and solids that can be ignited under almost all ambient temperature conditions.	3	Materials which in themselves are capable of detonation or explosive reaction but require a strong initiating source or which must be heated under confinement before initiation or which react explosively with water.
2	Materials which on intense or continued exposure could cause temporary incapacitation or possible residual injury unless prompt medical treatment is given.	2	Materials must be moderately heated or exposed to relatively high ambient temperatures before ignition can occur.	2	Materials that readily undergo violent chemical change at elevated temperatures and pressures; includes materials that react violently with water.
1	Materials which on exposure would cause irritation but only minor residual injury even if no treatment is given.	1	Materials that must be preheated before ignition can occur.	1	Materials which in themselves are normally stable, but which can become unstable at elevated temperatures and pressures.
0	Materials which on exposure under fire conditions would offer no hazard beyond that of ordinary combustible material.	0	Materials that will not burn.	0	Materials which in themselves are normally stable, even under fire exposure conditions, and which are not reactive with water.

FIGURE IV-2. (Continued). National Fire Protection Association (NFPA) identification of the hazards of materials.

EXAMPLE OF PLACARD AND PANEL WITH ID NUMBER

The Identification Number (ID No.) may be displayed on placards or on orange panels on tanks. Check the sides of the transport vehicle if the ID number is not displayed on the ends of the vehicle.

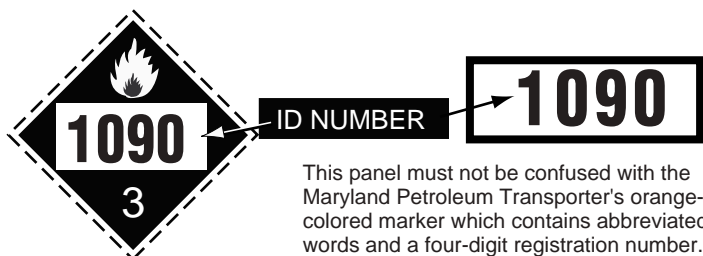

FIGURE IV-3. Example of US Department of Transportation (DOT) vehicle warning placard and panel with DOT identification number.

3. See **Table IV-4** (p 532) and specific chemicals covered in Section II of this manual.
 4. A variety of texts, journals, and computerized information systems are available but are of uneven scope or depth. See the reference list at the end of this section (p 517).
- C. Recognize dangerous environments.** In general, environments likely to expose the rescuer to the same conditions that caused grave injury to the victim are not safe for unprotected entry. **These situations require trained and properly equipped rescue personnel.** Examples include the following:
1. Any indoor environment where the victim was rendered unconscious or otherwise disabled.
 2. Environments causing acute onset of symptoms in rescuers, such as chest tightness, shortness of breath, eye or throat irritation, coughing, dizziness, headache, nausea, or loss of coordination.
 3. Confined spaces such as large tanks or crawlspaces. (Their poor ventilation and small size can result in extremely high levels of airborne contaminants. In addition, such spaces permit only a slow or strenuous exit, which may become physically impossible for an intoxicated individual.)
 4. Spills involving substances with poor warning properties or high vapor pressures (see p 530), especially when they occur in an indoor or enclosed environment. Substances with poor warning properties can cause serious injury without any warning signs of exposure such as smell or eye irritation. High vapor pressures increase the likelihood that dangerous air concentrations may be present. Also note that gases or vapors with a density greater than air may become concentrated in low-lying areas.
- D. Determine the potential for secondary contamination.** Although the threat of secondary contamination of emergency response personnel, equipment, and downstream facilities *may* be significant, it varies widely depending on the chemical, its concentration, and whether basic decontamination has already been performed. Not all toxic substances carry a risk of downstream contamination even though they may be extremely hazardous to rescuers in the hot zone. Exposures involving inhalation only and no external contamination do not pose a risk of secondary contamination.
1. Examples of substances with **no significant risk** for secondary contamination of personnel outside the hot zone are **gases**, such as carbon

monoxide, arsine, and chlorine, and **vapors**, such as those from xylene, toluene, or perchloroethylene.

2. Examples of substances with **significant potential** for secondary contamination and requiring aggressive decontamination and protection of downstream personnel include potent organophosphorus insecticides, oily nitro compounds, and highly radioactive compounds such as cesium or plutonium.
3. In many cases involving substances with a high potential for secondary contamination, this risk can be minimized by removal of grossly contaminated clothing and thoroughly cleansing the body in the contamination reduction corridor, including soap or shampoo wash. After these measures are followed, only rarely will the downstream medical team face significant persistent personal threat to their health from an exposed victim.

IV. Personal protective equipment. Personal protective equipment includes chemical-resistant clothing and gloves and protective respiratory gear. The use of such equipment should be supervised by experts in industrial hygiene or others with appropriate training and experience. Equipment that is incorrectly selected, improperly fitted, poorly maintained, or inappropriately used may provide a false sense of security and may fail, resulting in serious injury.

A. Protective clothing may be as simple as a disposable apron or as sophisticated as a fully encapsulated chemical-resistant suit. However, no chemical-resistant clothing is completely impervious to all chemicals over the full range of exposure conditions. Each suit is rated for its resistance to specific chemicals, and many are also rated for chemical breakthrough time.

B. Protective respiratory gear may be a simple paper mask, a cartridge filter respirator, or a positive-pressure air-supplied respirator. Respirators must be properly fitted for each user.

1. **A paper mask** might provide partial protection against gross quantities of airborne dust particles, but does not prevent exposure to gases, vapors, or fumes.
2. **Cartridge filter respirators** filter certain chemical gases and vapors out of the ambient air. They are used only when the toxic substance is known to be adsorbed by the filter, the airborne concentration is low, and there is adequate oxygen in the ambient air.
3. **Air-supplied respirators** provide an independent source of clean air. They may be fully self-contained units or masks supplied with air by a long hose. A **self-contained breathing apparatus** (SCBA) has a limited duration of air supply, from 5 to 30 minutes. Users must be fitted for their specific gear.

V. Victim management. Victim management includes rapid stabilization and removal from the Exclusion Zone, initial decontamination, delivery to emergency medical services personnel at the Support Zone perimeter, and medical assessment and treatment in the support area. Usually only the HazMat team or other fire department personnel with appropriate training and protective gear will be responsible for rescue from the hot zone, where skin and respiratory protection may be critical. Emergency medical personnel without specific training and appropriate equipment must not enter the hot zone unless it is determined to be safe by the Incident Commander and the medical officer.

A. Stabilization in the Exclusion Zone. If there is suspicion of trauma, the patient should be placed on a backboard and a cervical collar applied if appropriate. Position the patient so that the airway remains open. Gross contamination may be brushed off the patient. No further medical intervention can be expected from rescuers who are wearing bulky suits, masks, and heavy gloves. Therefore, every effort should be made to get the seriously ill patient out of this area as quickly as possible. Victims who are ambulatory should be directed to walk to the contamination reduction area.

B. Initial decontamination. Gross decontamination may take place in the Exclusion Zone (eg, brushing off chemical powder and removing soaked cloth-

ing), but most decontamination occurs in the contamination reduction corridor before the victim is transferred to waiting emergency medical personnel in the support area. Do not delay critical treatment while decontaminating the victim unless the nature of the contaminant makes such treatment too dangerous. Consult a regional poison control center ([800] 222-1222) for specific advice on decontamination. See also Section I, p 46.

1. Remove contaminated clothing and flush exposed skin, hair, or eyes with copious plain water from a high-volume, low-pressure fire hose. For oily substances, additional washing with soap or shampoo may be required. Ambulatory, cooperative victims may be able to perform their own decontamination.
2. For eye exposures, remove contact lenses if present, and irrigate eyes with plain water or, if available, normal saline dribbled from an intravenous bag. Continue irrigation until symptoms resolve or, if the contaminant is an acid or base, until the pH of the conjunctival sac is nearly normal (pH 6–8).
3. Double bag and save all removed clothing and jewelry.
4. Collect run-off water if possible, but generally rapid flushing of exposed skin or eyes should not be delayed because of environmental concerns. Remember that protection of health takes precedence over environmental concerns at a hazardous-materials incident.
5. For ingestions, if the material ingested is a suspected corrosive substance or the patient is experiencing painful swallowing or has oral burns, give the patient a glass of water to drink.
6. In the majority of incidents, basic victim decontamination as outlined above will substantially reduce or eliminate the potential for secondary contamination of downstream personnel or equipment. Procedures for cleaning equipment are contaminant-specific and depend on the risk of chemical persistence as well as toxicity.

C. Treatment in the support area. Once the patient is decontaminated (if required) and released into the support area, triage, basic medical assessment, and treatment by emergency medical providers may begin. In the majority of incidents, once the victim has been removed from the hot zone and is stripped and flushed, there is little or no risk of secondary contamination of these providers, and sophisticated protective gear is not necessary. Simple surgical latex gloves, a plain apron or disposable outer clothing is generally sufficient.

1. Maintain a patent airway and assist breathing if necessary (see pp 1–7). Administer supplemental oxygen.
2. Provide supportive care for shock (see p 16), arrhythmias (pp 10–15), coma (p 19), or seizures (p 22).
3. Treat with specific antidotes if appropriate and available.
4. Further skin, hair, or eye washing may be necessary. If the victim ingested a toxic substance, consider oral administration of **activated charcoal** (see p 51).
5. Take notes on the probable or suspected level of exposure for each victim, the initial symptoms and signs, and treatment provided. For chemicals with delayed toxic effects, this could be lifesaving.

VI. Ambulance transport and hospital treatment. For skin or inhalation exposures, no special precautions should be required if adequate decontamination has been carried out in the field prior to transport.

A. Patients who have ingested toxic substances may vomit en route; carry a large plastic bag-lined basin and extra towels to soak up and immediately isolate spillage. Vomitus may contain the original toxic material or even toxic gases created by action of stomach acid on the substance (eg, hydrogen cyanide from ingested cyanide salts). When performing gastric lavage in the emergency department, isolate gastric washings (eg, with a closed-wall suction container system).

B. For those unpredictable situations in which **a contaminated victim arrives at the hospital before decontamination**, it is important to have a strategy ready that will minimize exposure of hospital personnel:

1. Ask the local HazMat team to set up a contamination reduction area outside the hospital emergency department entrance. However, keep in mind that all teams may already be committed and not available to assist.
2. Prepare in advance a hose with 85°F water, soap, and an old gurney for rapid decontamination **outside** the emergency department entrance. Have a child's inflatable pool or another container ready to collect water runoff, if possible. However, do not delay patient decontamination if water runoff cannot be contained easily.
3. Do not bring patients soaked with liquids into the emergency department until they have been stripped and flushed outside, as the liquids may emit gas vapors and cause illness among hospital staff.
4. For incidents involving radioactive materials or other highly contaminating substances that are not volatile, utilize the hospital's radiation accident protocol, which will generally include the following:
 - a. Restricted access zones.
 - b. Isolation of ventilation ducts leading out of the treatment room to prevent spreading of the contamination throughout the hospital.
 - c. Paper covering for floors, and use of absorbent materials if liquids are involved.
 - d. Protective clothing for hospital staff (gloves, paper masks, shoe covers, caps, and gowns).
 - e. Double bagging and saving all contaminated clothing and equipment.
 - f. Monitoring to detect the extent and persistence of contamination (ie, using a Geiger counter for radiation incidents).
 - g. Notifying appropriate local, state, and federal offices of the incident and obtaining advice on laboratory testing and decontamination of equipment.

VII. Summary. The emergency medical response to a hazardous-materials incident requires prior training and planning to protect the health of response personnel and victims.

- A.** Response plans and training should be flexible. The level of hazard and the required actions vary greatly with the circumstances at the scene and the chemicals involved.
- B.** First responders should be able to do the following:
1. Recognize potentially hazardous situations.
 2. Take steps to protect themselves from injury.
 3. Obtain accurate information about the identity and toxicity of each chemical substance involved.
 4. Use appropriate protective gear.
 5. Perform victim decontamination before transport to a hospital.
 6. Provide appropriate first aid and advanced supportive measures as needed.
 7. Coordinate their actions with other responding agencies such as the HazMat team, police and fire departments, and regional poison control centers.

► EVALUATION OF THE PATIENT WITH OCCUPATIONAL CHEMICAL EXPOSURE

Paul D. Blanc, MD MSPH

This chapter highlights common toxicological problems in the workplace. Occupationally related disease is commonly seen in the outpatient setting. Estimates of the proportion of occupationally related medical problems in primary care practices range up to 15–20%, although this includes many patients with musculoskeletal complaints. However, approximately 5% of all symptomatic poison control center consultations are occupational in nature, suggesting a large number of chemical exposures. The largest single referring group for these calls is emergency medicine specialists.

I. General considerations

A. Occupational illness is rarely pathognomonic. The connection between illness and workplace factors is typically obscure unless a specific effort is made to link exposure to disease.

1. Massive or catastrophic events leading to acute onset of symptoms, such as an irritant gas release, are relatively uncommon.
2. For most workplace exposures, symptom onset is more often insidious, following a subacute or chronic pattern, as in heavy metal poisoning.
3. Long latency, often years, between exposure and disease makes linking cause and effect even more difficult, for example in chronic lung disease or in occupationally related cancer.

B. Occupational evaluation frequently includes legal and administrative components

1. Occupational illness, even if suspected but not established, may be a reportable illness in certain states (eg, in California through the Doctor's First Report system).
2. Establishing quantifiable documentation of adverse effects at the time of exposure may be critical to future attribution of impairment (for example, spirometric evaluation soon after an irritant inhalant exposure).
3. Although workers' compensation is in theory a straightforward "no-fault" insurance system, in practice it is often arcane and adversarial. It is important to remember that the person being treated is the patient, not the employer or a referring attorney.

II. Components of the occupational exposure history

A. Job and job process

1. Ask specifics about the job. Do not rely on descriptions limited to a general occupation or trade such as "machinist," "painter," "electronics worker," or "farmer."
2. Describe the industrial process and equipment used on the job. If power equipment is used, ascertain how is it powered to assess carbon monoxide exposure risk.
3. Determine whether the work process utilizes a closed (eg, a sealed reaction vat) system or an open system and what other processes or work stations are nearby. Work under a lab hood may be an effectively "closed" system, but not if the window is raised too far or if the airflow is not calibrated.

4. Find out who does maintenance and how often it is done.

B. Level of exposure

1. Ask whether dust or mist can be seen in the air at the worksite. If so, question whether coworkers or nearby objects can be seen clearly (very high levels will actually obscure sight). A history of dust-laden sputum or nasal discharge at the end of the work shift is also a marker of heavy exposure.
2. Ask whether work surfaces are dusty or damp and whether the paint at the worksite is peeling or discolored (eg, from a corrosive atmosphere).
3. Determine whether strong smells or tastes are present and, if so, whether they diminish over time, suggesting olfactory fatigue.
4. Find out whether there is any special ventilation system and where the fresh air intake is located (toxins can actually be recirculated by a poorly placed air intake system).
5. Establish whether the person has direct skin contact with the materials worked with, especially solvents or other liquid chemicals.
6. Confined-space work can be especially hazardous. Examples of such spaces include ship holds, storage tanks, and underground vaults.

C. Personal protective gear (see also p 515). Respiratory system and skin protection may be essential for certain workplace exposures. Just as important as availability of equipment are its proper selection and use.

1. **Respiratory protection.** A disposable paper-type mask is inadequate for most exposures. A screw-in cartridge-type mask for which the cartridges are rarely changed is also unlikely to be effective. For an air-supplied respirator with an air supply hose, ascertain the location of the air intake.
2. **Skin protection.** Gloves and other skin protection should be impervious to the chemical(s) used.

D. Temporal aspects of exposure

1. The most important question is whether there have been any changes in work process, products used, or job duties which could be temporally associated with the onset of symptoms.
2. Patterns of recurring symptoms linked to the work schedule can be important, for example if symptoms are different on the first day of the work week, at the end of the first shift of the week, at the end of the work week, or on days off or vacation days.

E. Other aspects of exposure

1. It is critical to assess whether anyone else from the workplace is also symptomatic and, if so, to identify their precise job duties.
2. Eating in work areas can result in exposure through ingestion; smoking on the job can lead to inhalation of native materials or of toxic pyrolysis products.
3. Determine whether a uniform is provided and who launders it. For example, family lead poisoning can occur through work clothes brought home for laundering. After certain types of contamination (eg, with pesticides), a uniform should be destroyed, not laundered and reused.
4. Find out how large the worksite is, since small operations are often the most poorly maintained. An active work safety and health committee suggests that better general protection is in place.

F. Common toxic materials of frequent concern that are commonly addressed in the occupational exposure history

1. **Two-part glues, paints, or coatings** that must be mixed up just prior to use, such as urethanes and epoxides. These reactive polymers are often irritants or sensitizers.
2. **Solvents or degreasers**, especially if exposure is high enough to cause dizziness, nausea, headache, or a sense of intoxication.
3. **Respirable dusts**, including friable insulation or heat-resistant materials, and sand or quartz dust, especially from grinding or blasting.
4. **Combustion products or fumes** from fires, flame cutting, welding, or other high-temperature processes.

- G. Identifying the specific chemical exposures involved may be difficult because the worker may not know or may not have been told their precise identification. Even the manufacturer may be uncertain because components of the chemical mixture were obtained elsewhere or because exposure is due to undetermined process by-products. Finally, the exposure may have occurred long before. Aids to exposure identification include the following:
1. **Product labels.** Obtain product labels as a first step. However, the label alone is unlikely to provide detailed information.
 2. **Material safety data sheets.** Contact the manufacturer directly for a material safety data sheet (MSDS). These must be provided upon a physician's request in cases of suspected illness. Do not take "no" for an answer. You may need to supplement the MSDS information through direct discussion with a technical person working for the supplier.
 3. **Computerized databases.** Consult computerized databases (eg, Poisindex, TOMES, NIOSHTIC, others) for further information. Regional poison control centers ([800] 222-1222) can be extremely useful.
 4. **DOT identification placards.** In cases of transportation release, Department of Transportation (DOT) identification placards may be available (see p 512).
 5. **Industrial exposure data.** Rarely, detailed industrial hygiene data may be available to delineate specific exposures and exposure levels in cases of ongoing, chronic exposure.
 6. **Existing process exposure data.** Often, exposure is assumed on the basis of known specific exposures linked to certain work processes. Selected types of exposure are listed in Table IV-1.
- III. **Organ-specific occupational toxidromes.** A list of *Ten Leading Causes of Occupational Injuries and Illnesses* has been published by the National Institute for Occupational Safety and Health (NIOSH). This list, organized generally by organ system, is included in Table IV-2, along with additional disorders not on the original NIOSH list.
- A. **Occupational lung diseases**
1. In acute pulmonary injury from **inhaled irritants**, exposure is typically brief and intense; initial symptom onset is within minutes to 24-48 hours after exposure. The responses to irritant exposure, in increasing severity, are mucous membrane irritation, burning eyes and runny nose, tracheobronchitis, hoarseness, cough, laryngospasm, bronchospasm, and pulmonary edema progressing to adult respiratory distress syndrome (ARDS). Lower water solubility gases (nitrogen dioxide, ozone, and phosgene) may produce little upper airway mucous membrane irritation. Any irritant (high or low solubility) can cause pulmonary edema after sufficient exposure.
 2. **Heavy metal** pneumonitis is clinically similar to irritant inhalation injury. As with low-solubility gases, upper-airway mucous membrane irritation is minimal; thus, the exposure may have poor warning properties. Offending agents include cadmium, mercury, and, in limited industrial settings, nickel carbonyl.
 3. **Febrile inhalational syndromes** are acute, self-limited flu-like syndromes including **metal fume fever** (caused by galvanized-metal fumes), **polymer fume fever** (after thermal breakdown of certain fluoropolymers), and "**organic dust toxic syndrome**" (ODTS) (after heavy exposure to high levels of organic dust such as occurs in shoveling wood chip mulch). In none of these syndromes is lung injury marked. The presence of hypoxemia or lung infiltrates suggests an alternative diagnosis.
 4. **Work-related asthma** is a frequent occupational problem. Classic occupational asthma typically occurs after sensitization to either high-molecular-weight chemicals (eg, inhaled foreign proteins) or to small chemicals that appear to act as haptens (the most common of which are the urethane isocyanates such as **toluene diisocyanate** [TDI]). After acute, high-level irritant inhalations, for example of **chlorine**, a chronic irritant-induced

TABLE IV-1. SELECTED JOB PROCESSES AT HIGH RISK OF SPECIFIC TOXIC EXPOSURES

Job Process	Exposure
Aerospace and other specialty metal work	Beryllium
Artificial nail application	Methacrylate
Artificial nail removal	Acetonitrile, nitroethane
Artificial leather making, fabric coating	Dimethylformamide
Auto body painting	Isocyanates
Battery recycling	Lead fumes and dust
Carburetor cleaning (car repair)	Methylene chloride
Cement manufacture	Sulfur dioxide
Commercial refrigeration	Ammonia, sulfur dioxide
Concrete application	Chromic acid
Custodial work	Chlorine (hypochlorite + acid mix)
Dry cleaning	Chlorinated hydrocarbon solvents
Explosives work	Nitrate oxidants
Epoxy glue and coatings use	Trimellitic anhydride
Fire fighting	Carbon monoxide, cyanide, acrolein
Fumigation	Methyl bromide, Vikane™ (sulfuryl fluoride), phosphine
Furniture refinishing	Methylene chloride
Gas-shielded welding	Nitrogen dioxide
Gold refining	Mercury vapor
Hospital sterilizer work	Ethylene oxide, glutaraldehyde
Indoor fork lift or compressor operation	Carbon monoxide
Manure pit operation	Hydrogen sulfide
Metal degreasing	Chlorinated hydrocarbon solvents
Metal plating	Cyanide, acid mists
Microelectronics chip etching	Hydrofluoric acid
Microelectronic chip doping	Arsine gas, diborane gas
Paper pulp work	Chlorine, chlorine dioxide
Pool and hot tub disinfection	Chlorine, bromine
Pottery glazing and glassmaking	Lead dust
Radiator repair	Lead fumes
Rayon manufacturing	Carbon disulfide
Rubber cement glue use	<i>n</i> -Hexane, other solvents
Rocket and jet fuel work	Hydrazine, monomethylhydrazine
Sandblasting	Silica dust
Sewage work	Hydrogen sulfide
Silo work with fresh silage	Nitrogen dioxide
Sheet-metal flame cutting or brazing	Cadmium fumes
Structural paint refurbishing	Lead dust
Water treatment or purification	Chlorine, ozone
Welding galvanized steel	Zinc oxide fumes
Welding solvent-contaminated metal	Phosgene

TABLE IV-2. LEADING WORK-RELATED DISEASES AND INJURIES AND THEIR RELEVANCE TO CLINICAL TOXICOLOGY

Work-Related Conditions	NIOSH*	Relevance	Examples of Relevant Conditions
Occupational lung disease	Yes	High	Irritant inhalation
Musculoskeletal	Yes	Low	Chemical-related Raynaud's syndrome
Cancer	Yes	Low	Acute leukemia
Trauma	Yes	Low	High-pressure injury
Cardiovascular disease	Yes	Moderate	Carbon monoxide ischemia
Disorders of reproduction	Yes	Low	Spontaneous abortion
Neurotoxic disorders	Yes	High	Acetylcholinesterase inhibition
Noise-induced hearing loss	Yes	Low	Potential drug interactions
Dermatologic conditions	Yes	Moderate	Hydrofluoric acid burn
Psychologic disorders	Yes	Moderate	Postexposure stress disorder
Hepatic injury	No	High	Chemical hepatitis
Renal disease	No	Moderate	Acute tubular necrosis
Hematologic conditions	No	High	Methemoglobinemia
Physical exposures	No	Low	Radiation sickness
Systemic illness	No	High	Cyanide toxicity

*NIOSH = National Institute for Occupational Safety and Health list of 10 leading conditions.

asthma may persist (sometimes called reactive airways dysfunction syndrome or RADS).

5. **Chronic fibrotic occupational lung diseases** include **asbestosis** (see p 121), **silicosis**, **coal workers' pneumoconiosis**, and a few other less common fibrotic lung diseases associated with occupational exposures to such substances as **beryllium** and hard metal (**cobalt-tungsten carbide**). These conditions occur after years of exposure and with long latency, although patients may present for evaluation after an acute exposure. Referral for follow-up surveillance is appropriate if exposure is anticipated to be long term.

6. **Hypersensitivity pneumonitis** (also called **allergic alveolitis**) includes a group of diseases caused by chronic exposure to organic materials, especially thermophilic bacteria. The most common of these is "**farmer's lung**." Although the process is chronic, acute illness can occur in a sensitized host after heavy exposure to the offending agent. In such cases the illness may need to be differentiated from exposure to an irritant inhalant leading to acute lung injury.

B. **Musculoskeletal** conditions, including acute mechanical trauma, are the most common occupational medicine problem but rarely have direct toxicological implications.

1. **Raynaud's syndrome** may rarely be associated with chemical exposure (eg, vinyl chloride monomer).

2. **High-pressure injection injuries** (eg, from paint spray guns) are important not because of systemic toxicity due to absorption of an injected substance (eg, paint thinner) but because of extensive irritant-related tissue necrosis. Emergency surgical evaluation of such cases is mandatory.

C. **Occupational cancer** is a major public concern and often leads to referral for toxicological evaluation. A variety of different cancers have been associated with workplace exposure, some more strongly than others. Identifying the

chemical causes of cancer has proved a great challenge for occupational toxicologists and epidemiologists. Often, the practitioner is faced with an individual patient who seeks an assessment of the relative attribution of disease due to chemical exposures in that particular case, for purposes of gaining compensation or establishing liability. This process, however, tends to be far removed from the acute care setting, and clinical oncology management is not impacted directly by such etiologic considerations.

D. Cardiovascular disease

1. **Atherosclerotic** cardiovascular disease is associated with **carbon disulfide**. This chemical solvent is used in rayon manufacturing and in specialty applications and research laboratories. It is also a principal metabolite of **disulfiram**.
2. **Carbon monoxide** at high levels can cause myocardial infarction in otherwise healthy individuals and, at lower levels, can aggravate ischemia in the face of established atherosclerotic heart disease (ASHD). Chronic exposure to carbon monoxide may also be associated with ASHD. Many jurisdictions automatically grant workers' compensation to firemen or policemen with ASHD, regarding it as a "stress-related" occupational disease. This is related to social policy rather than established epidemiologic risk.
3. **Nitrate withdrawal-induced** coronary artery spasm has been reported among workers heavily exposed to nitrates during munitions manufacturing.
4. **Hydrocarbon solvents**, especially chlorinated hydrocarbons, and chlorofluorocarbon propellants all enhance the sensitivity of the myocardium to catecholamine-induced dysrhythmias.

E. Adverse reproductive outcomes

have been associated with or implicated in occupational exposures to **heavy metals** (lead and organic mercury), hospital chemical exposures (including **anesthetic and sterilizing gases**), and **dibromochloropropane** (a soil fumigant now banned in the United States).

F. Occupational neurotoxins

1. **Acute** central nervous system (CNS) toxicity can occur with many pesticides (including both cholinesterase-inhibiting and chlorinated hydrocarbons). The CNS is also the target of **methyl bromide** (a structural fumigant; see p 263). Cytotoxic and anoxic asphyxiant gases (eg, carbon monoxide, cyanide, and hydrogen sulfide) all cause acute CNS injury. **Hydrocarbon solvents** (see p 219) are typically CNS depressants at high exposure levels.
2. **Chronic** CNS toxicity is the hallmark of heavy metals. This includes inorganic forms (**arsenic, lead, and mercury**) and organic forms (tetraethyl lead and methyl mercury). Chronic **manganese** (see p 251) exposure can cause psychosis and parkinsonism. Postanoxic injury, especially from **carbon monoxide** (p 151), can also lead to parkinsonism.
3. Established causes of **peripheral neuropathy** include lead, arsenic, mercury, carbon disulfide (mentioned earlier in connection with ASHD), *n*-hexane, and certain organophosphates.

G. Occupational ototoxicity

is common but is usually noise induced rather than chemical related. Preexisting noise-induced hearing loss may magnify the impact of common ototoxic drugs.

H. Occupational skin disorders

1. Allergic and irritant contact dermatitis and acute caustic chemical or acid injuries are the most common toxin-related skin problems. Systemic toxicity may occur (p 157) but is not a common complicating factor.
2. **Hydrofluoric acid** burns present a specific set of management problems (see p 221). Relevant occupations include not only the microelectronics industry but maintenance or repair jobs in which hydrofluoric acid-containing rust removers are used.

I. Work-related psychological disorders

include a heterogeneous mix of diagnoses. Of these, "post-traumatic stress disorder" and "mass psychogenic

illness" can be extremely relevant to medical toxicology because the patients in these cases may believe that their symptoms have a chemical etiology. After reasonable toxicological causes have been excluded, psychological diagnoses should be considered when nonspecific symptoms or multiple somatic complaints cannot be linked to abnormal signs or physiologic effects.

J. Occupational chemical hepatotoxins (see also p 40)

1. Causes of acute chemical hepatitis include exposure to industrial solvents such as **halogenated hydrocarbons** (methylene chloride, trichloroethylene, and trichloroethane); carbon tetrachloride (only rarely encountered in modern industry); and **dimethylformamide**, **dinitropropane**, and **dimethylacetamide**. The jet and rocket fuel components **hydrazine** and **monomethylhydrazine** are also potent hepatotoxins.
2. Other hepatic responses that can be occupationally related include steatosis, cholestatic injury, hepatoportal sclerosis, and hepatic porphyria. The acute care provider should always consider a toxic chemical etiology in the differential diagnosis of liver disease.

K. Renal diseases

1. **Acute tubular necrosis** can follow high-level exposure to a number of toxins, although the more frequent exposure scenario is a suicide attempt rather than workplace inhalation.
2. **Interstitial nephritis** is associated with chronic exposure to heavy metals, while hydrocarbon exposure has been associated epidemiologically with **glomerular nephritis**, particularly Goodpasture's disease.

L. Hematologic toxicity

1. Industrial oxidants are an important potential cause of chemically induced **methemoglobinemia** (see p 261), especially in the dyestuff and munitions industries.
2. **Bone marrow** is an important target organ for certain chemicals, such as **benzene** and **methyl cellosolve**. Both can cause pancytopenia. Benzene exposure also causes leukemia in humans. **Lead** causes anemia through interference with hemoglobin synthesis.
3. **Arsine gas** is a potent cause of massive hemolysis. It is of industrial importance in microelectronics manufacturing.

M. Nonchemical physical exposures in the workplace are important because they can cause systemic effects that mimic chemical toxidromes. The most important example is **heat stress**, which is a major occupational health issue. Other relevant nonchemical, work-related physical exposure types include **ionizing radiation**, **nonionizing radiation** (such as ultraviolet, infrared, and microwave exposure), and **increased barometric pressure** (eg, among caisson workers). Except for extremes of exposure, the adverse effects of these physical factors are generally associated with chronic conditions.

N. Systemic poisons fit poorly into organ system categories, but are clearly of major importance in occupational toxicology. Prime examples are the cytotoxic asphyxiants **hydrogen cyanide** (especially in metal plating and metal refining) (see p 177), **hydrogen sulfide** (important as a natural by-product of organic material breakdown) (p 224), and **carbon monoxide** (principally encountered as a combustion by-product, but also a metabolite of the solvent methylene chloride) (p 265). **Arsenic** (p 115) is a multiorgan toxin with a myriad of effects. It has been widely used in agriculture and is an important metal smelting by-product. A systemic **disulfiram reaction** (p 186) can occur as a drug interaction with coexposure to certain industrial chemicals. Toxicity from **dinitrophenol**, an industrial chemical that uncouples oxidative phosphorylation, is also best categorized as a systemic effect.

IV. Laboratory testing

A. Testing for specific occupational toxins has a limited, but important role. Selected tests are listed in the descriptions of specific substances in Section II of this book.

- B. For significant irritant inhalation exposures, in addition to assessing oxygenation and chest radiographic status, early spirometric assessment is often important.
- C. General laboratory testing for chronic exposure assessment should be driven by the potential organ toxicity delineated previously. Standard recommendations (eg, in NIOSH criteria documents) often include a complete blood count, electrolytes, tests of renal and liver function, and periodic chest radiographic and pulmonary function studies.

V. Treatment

- A. Elimination or reduction of further exposure is a key treatment intervention in occupational toxicology. This includes prevention of exposure of coworkers. The **Occupational Safety and Health Administration (OSHA)** may be of assistance and should be notified immediately about an ongoing, potentially life-threatening workplace exposure situation. Contact information for regional OSHA offices is listed in Table IV–3. Workplace modification and control, especially the substitution of less hazardous materials, should always be the first line of defense. Worker-required personal protective equipment is, in general, less preferred.
- B. The medical treatment of occupational toxic illness should follow the general principles outlined earlier in this section and in Sections I and II of this book. In particular, the use of specific antidotes should be undertaken in consultation with a regional poison control center ([800] 222-1222) or other specialists. This is particularly true before chelation therapy is initiated for heavy metal poisoning.

TABLE IV–3. REGIONAL OFFICES OF THE OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION (OSHA)

Region	Regional Office	Phone Number ^a	States Served
I	Boston	(617) 565–9860	Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, Vermont
II	New York City	(212) 337–2378	New York, New Jersey, Puerto Rico, Virgin Islands
III	Philadelphia	(215) 861–4900	Delaware, District of Columbia, Maryland, Pennsylvania, Virginia, West Virginia
IV	Atlanta	(404) 562–2300	Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, Tennessee
V	Chicago	(312) 353–2220	Illinois, Indiana, Michigan, Minnesota, Ohio, Wisconsin
VI	Dallas	(214) 767–4731	Arkansas, Louisiana, New Mexico, Oklahoma, Texas
VII	Kansas City	(816) 426–5861	Iowa, Kansas, Missouri, Nebraska
VIII	Denver	(303) 844–1600	Colorado, Montana, North Dakota, South Dakota, Utah, Wyoming
IX	San Francisco	(415) 975–4310	Arizona, California, Hawaii, Nevada, American Samoa, Guam
X	Seattle	(206) 553–5930	Alaska, Idaho, Oregon, Washington

► THE TOXIC HAZARDS OF INDUSTRIAL AND OCCUPATIONAL CHEMICALS

Kent R. Olson, MD, and Patricia Hess Hiatt, BS

Basic information on the toxicity of many of the most commonly encountered and toxicologically significant industrial chemicals is provided in Table IV–4. The table is intended to expedite the recognition of potentially hazardous exposure situations and therefore provides information such as vapor pressures, warning properties, physical appearance, occupational exposure standards and guidelines, and hazard classification codes, which may also be useful in the assessment of an exposure situation. Table IV–4 is divided into 3 sections: **health hazards**, **exposure guidelines**, and **comments**. To use the table correctly, it is important to understand the scope and limitations of the information it provides.

The chemicals included in Table IV–4 were selected based on the following criteria: (1) toxic potential; (2) prevalence of use; (3) public health concern; and (4) availability of adequate toxicologic, regulatory, and physical- and chemical-property information. Several governmental and industrial lists of “hazardous chemicals” were used. A number of chemicals were omitted because no toxicologic information could be found, there are no regulatory standards, or they have very limited use. Chemicals that were of specific interest, those with existing exposure recommendations, and those of high use (even if of low toxicity) were included.

I. Health hazard information. The health hazards section of Table IV–4 focuses primarily on the basic hazards associated with possible inhalation of or skin exposure to chemicals in a workplace. It is based almost entirely on the occupational health literature. Most of our understanding of the potential effects of chemicals on human health is derived from occupational exposures, the levels of which are typically many times greater than those of environmental exposures. Moreover, the information in Table IV–4 unavoidably emphasizes *acute* health effects. Much more is known about the acute effects of chemicals on human health than about their chronic effects. The rapid onset of symptoms after exposure makes the causal association more readily apparent for acute health effects.

- A.** The table is *not* a comprehensive source of the toxicology and medical information needed to manage a severely symptomatic or poisoned patient. Medical management information and advice for specific poisonings are found in Section I (see pulmonary problems, pp 1–8, and pulmonary and skin decontamination, pp 46–47) and Section II (see caustics and corrosives, p 157; gases, p 213; and hydrocarbons, p 219).
- B. Hydrocarbons,** broadly defined as chemicals containing carbon and hydrogen, make up the majority of substances in Table IV–4. Hydrocarbons have a wide range of chemical structures and, not surprisingly, a variety of toxic effects. There are a few common features of hydrocarbon exposure, and the reader is directed to Section II, p 219, for information on general diagnosis and treatment. Some common features include the following:
- 1. Skin.** Dermatitis caused by defatting or removal of oils in the skin is common, especially with prolonged contact. Some agents can cause frank burns.
 - 2. Arrhythmias.** Many hydrocarbons, most notably fluorinated, chlorinated, and aromatic compounds, can sensitize the heart to arrhythmogenic ef-

fects of epinephrine, resulting in premature ventricular contractions (PVCs), ventricular tachycardia, or fibrillation. Even simple aliphatic compounds such as butane occasionally can cause this effect.

- a. Because arrhythmias may not occur immediately, cardiac monitoring for 24 hours is recommended for all victims who have had significant hydrocarbon exposure (eg, syncope, coma, and arrhythmias).
 - b. Ventricular arrhythmias are preferably treated with a beta-adrenergic blocker (eg, esmolol [p 443] or propranolol [p 496]) rather than lidocaine.
3. **Pulmonary aspiration** of most hydrocarbons, especially those with relatively high volatility and low viscosity (eg, gasoline, kerosene, and naphtha) can cause severe chemical pneumonitis.
- C. **Carcinogens.** To broaden the scope of the table, findings from human and animal studies relating to the carcinogenic or reproductive toxicity of a chemical are included when available. The **International Agency for Research on Cancer (IARC)** is the foremost authority in evaluating the carcinogenic potential of chemical agents for humans. The overall IARC evaluations are provided, when available, in the health hazards section of the table. The following IARC ratings are based primarily upon human and animal data:
1. **IARC 1** substances are considered human carcinogens; generally there is sufficient epidemiologic information to support a causal association between exposure and human cancer.
 2. **IARC 2** compounds are suspected of being carcinogenic to humans based on a combination of data from animal and human studies. Group IARC 2 is subdivided into two parts:
 - a. An **IARC 2A** rating indicates that a chemical is *probably* carcinogenic to humans. Most often there is limited evidence of carcinogenicity in humans combined with sufficient evidence of carcinogenicity in animals.
 - b. **IARC 2B** indicates that a chemical is *possibly* carcinogenic to humans. This category may be used when there is limited evidence from epidemiologic studies and less than sufficient evidence for carcinogenicity in animals. It also may be used when there is inadequate evidence of carcinogenicity in humans and sufficient evidence in animals.
 3. **IARC 3** substances cannot be classified in regard to their carcinogenic potential for humans because of inadequate data.
 4. If a chemical is described in the table as carcinogenic but an IARC category is not given, IARC has not classified the chemical, but other sources (eg, US Environmental Protection Agency and California Department of Health Services Hazard Evaluation Service and Information System) consider it carcinogenic.
- D. **Problems in assessing health hazards.** The nature and magnitude of the health hazards associated with occupational or environmental exposures to any chemical depend on its intrinsic toxicity and the conditions of exposure.
1. Characterization of these hazards is often difficult. Important considerations include the potency of the agent, the route of exposure, the level and temporal pattern of exposure, genetic susceptibility, overall health status, and life-style factors that may alter individual sensitivities (eg, alcohol consumption may cause "degreaser's flush" in workers exposed to trichloroethylene). Despite their value in estimating the likelihood and potential severity of an effect, quantitative measurements of the level of exposure are not often available.
 2. Hazard characterizations cannot address undiscovered or unappreciated health effects. The limited information available on the health effects of most chemicals makes this a major concern. For example, of the more than 5 million compounds known to science, only about 100,000 are listed in the *Registry of the Toxic Effects of Chemical Substances* (RTECS) published by the National Institute for Occupational Safety and Health (NIOSH). Of these 100,000 substances, fewer than 5000 have any toxicity

studies relating to their potential tumorigenic or reproductive effects in animals or humans. Because of these gaps, the absence of information does not imply the absence of hazard.

3. The predictive value of animal findings for humans is sometimes uncertain. For many effects, however, there is considerable concordance between test animals and humans.
4. The developmental toxicity information presented here is not a sufficient basis on which to make clinical judgments as to whether a given exposure might adversely affect a pregnancy. For most chemicals known to have adverse effects on fetal development in test animals, there are insufficient epidemiologic data in humans. The predictive value of these animal findings for humans, who are typically exposed to levels much lower than those used in animal tests, is thought to be poor. In general, so little is known about the effects of substances on fetal development that it is prudent to conservatively manage all chemical exposures. The information here is presented solely to identify those compounds for which available data further indicate the need to control exposures.

II. Exposure guidelines and National Fire Protection Association rankings

- A. **Threshold limit values (TLVs)** are workplace exposure guidelines established by the American Conference of Governmental Industrial Hygienists (ACGIH), a professional society. Although the ACGIH has no regulatory authority, its recommendations are highly regarded and widely followed by the occupational health community. The toxicologic basis for each TLV varies. A TLV may be based on such diverse effects as respiratory sensitization, sensory irritation, narcosis, or asphyxia. Therefore, the TLV is not a relative index of toxicity. Because the degree of health hazard is a continuous function of exposure, TLVs are not fine lines separating safe from dangerous levels of exposure. The *Documentation of the Threshold Limit Values*, which is published by the ACGIH and describes in detail the rationale for each value, should be consulted for specific information on the toxicologic significance of a particular TLV. Common units for a TLV are parts of chemical per million parts of air (**ppm**) and milligrams of chemical per cubic meter of air (**mg/m³**). **At standard temperature and pressure, TLV values in ppm can be converted to their equivalent concentrations in mg/m³** by multiplying the TLV in ppm by the molecular weight (MW) in milligrams of the chemical and dividing the result by 22.4 (one mole of gas displaces 22.4 L of air at standard temperature and pressure):

$$\text{mg/m}^3 = \frac{\text{ppm} \times \text{MW}}{22.4}$$

1. The **threshold limit value time-weighted average (TLV-TWA)** refers to airborne contaminants and is the time-weighted average concentration to which nearly all workers may be repeatedly exposed during a normal 8-hour workday and 40-hour work week, without adverse effect. Unless otherwise indicated, the values listed under the ACGIH TLV heading are the TLV-TWA values. Because TLV-TWA values are often set to protect against worker discomfort, nonspecific minor health complaints such as eye or throat irritation, cough, headache, or nausea may indicate overexposure.
2. The **threshold limit value ceiling (TLV-C)** is the airborne concentration that should not be exceeded during any part of a working exposure. Ceiling guidelines are often set for rapidly acting agents for which an 8-hour time-weighted average exposure limit would be inappropriate. TLV-Cs are listed under the ACGIH TLV heading and are noted by a "(C)."
3. Compounds for which **skin contact** is a significant route of exposure are designated with an "**S**." This could refer to potential corrosive effects or systemic toxicity owing to skin absorption.

4. The ACGIH classifies some substances as being **confirmed (A1) or suspected (A2) human carcinogens, or animal carcinogens (A3)**. These designations are also provided in the table. The ACGIH does not consider A3 carcinogens likely to cause human cancer.
 5. The TLVs are heavily based on workplace exposures and conditions occurring within the United States. Their application, which requires training in industrial hygiene, is therefore limited to similar exposures and conditions.
- B. OSHA regulations** are standards for exposure to airborne contaminants, set and enforced by OSHA, an agency of the federal government.
1. The **permissible exposure limit (PEL)** set by OSHA is closely analogous to the ACGIH TLV-TWA. In fact, when OSHA was established in 1971, it formally adopted the 1969 ACGIH TLVs for nearly all of its PELs. In 1988, OSHA updated the majority of its PELs by adopting the 1986 TLVs. These revised PELs were printed in the 1990 edition of this manual. However, in early 1993, the 1988 PEL revisions were voided as a result of legal challenges, and the earlier values were restored. Because these restored values cannot be reliably assumed to protect worker health, and because the values may change again as a result of further administrative or legislative action, the PELs are not printed in this edition.
 2. Substances that are specifically **regulated as carcinogens** by OSHA are indicated by "**OSHA CA**" under the ACGIH TLV heading. For these carcinogens, additional regulations apply. The notation "**NIOSH CA**" in the TLV column identifies those chemicals that NIOSH recommends be treated as potential human carcinogens.
 3. Some states operate their own occupational health and safety programs in cooperation with OSHA. In these states, stricter standards may apply.
- C. Immediately dangerous to life or health (IDLH)** represents "a maximum concentration from which one could escape within 30 minutes without any escape-impairing symptoms or any irreversible health effects." The IDLH values were originally jointly set by OSHA and NIOSH for the purpose of respirator selection. They have recently been updated by NIOSH.
- D. Emergency Response Planning Guidelines (ERPGs)** have been developed by the American Industrial Hygiene Association (AIHA) for 70 specific substances. The values are generally based upon limited human experience as well as available animal data and should be considered estimates. Although these values are printed in the IDLH column, they have different meanings:
1. **ERPG-1** is "the maximum air concentration below which it is believed nearly all individuals could be exposed for up to 1 hour without experiencing other than mild transient adverse health effects or perceiving a clearly defined objectionable odor."
 2. **ERPG-2** is "the maximum air concentration below which it is believed that nearly all individuals could be exposed for up to 1 hour without experiencing or developing irreversible or other serious health effects or symptoms which could impair their abilities to take protective action."
 3. **ERPG-3** is "the maximum air concentration below which it is believed that nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects."
 4. The ERPGs were developed for purposes of emergency planning and response. They are not exposure guidelines and do not incorporate the safety factors normally used in establishing acceptable exposure limits. Reliance on the ERPGs for exposures lasting longer than 1 hour is not safe.
- E. National Fire Protection Association (NFPA) codes** are part of the system created by the NFPA for identifying and ranking the potential fire hazards of materials. The system has three principal categories of hazard: **health (H)**, **flammability (F)**, and **reactivity (R)**. Within each category, hazards are ranked from four (4), indicating a severe hazard, to zero (0), indicating no

special hazard. The NFPA rankings for each substance are listed under their appropriate headings. The criteria for rankings within each category are found in Figure IV-2, p 512.

1. The NFPA health hazard rating is based on both the intrinsic toxicity of a chemical and the toxicities of its combustion or breakdown products. The overall ranking is determined by the greater source of health hazard under fire or other emergency conditions. Common hazards from the ordinary combustion of materials are not considered in these rankings.
2. This system is intended to provide basic information to fire-fighting and emergency-response personnel. Its application to specific situations requires skill. Conditions at the scene, such as the amount of material involved and its rate of release, wind conditions, and the proximity to various populations and their health status, are as important as the intrinsic properties of a chemical in determining the magnitude of a hazard.

III. Comments section. The comment column of Table IV-4 provides supplementary information on the physical and chemical properties of substances, which would be helpful in assessing their health hazards. Information such as physical state and appearance, vapor pressures, warning properties, and potential breakdown products is included.

- A. Information on physical state and appearance** of a compound may help in its identification and indicate whether dusts, mists, vapors, or gases are likely means of airborne exposure. **Note:** For many products, especially pesticides, appearance and some hazardous properties may vary with the formulation.
- B. The vapor pressure** of a substance determines its potential maximum air concentration and influences the degree of inhalation exposure or airborne contamination. Vapor pressures fluctuate greatly with temperature.
 1. Substances with high vapor pressures tend to volatilize more quickly and can reach higher maximum air concentrations than substances with low vapor pressures. Some substances have such low vapor pressures that airborne contamination is a threat only if they are finely dispersed in a dust or mist.
 2. Substances with a **saturated-air concentration** below their TLVs do not pose a significant vapor inhalation hazard. Vapor pressures can be roughly converted to saturated-air concentrations expressed in parts per million by multiplying by a factor of 1300. This is equivalent to dividing by 760 mm Hg and then multiplying the result by 1 million to adjust for the original units of parts per million (a pressure of 1 equals 760 mm Hg):

$$\text{ppm} = \frac{\text{Vapor pressure (mm Hg)}}{760} \times 10^6$$

C. Warning properties, such as odor and sensory irritation, can be valuable indicators of exposure. However, because of olfactory fatigue and individual differences in odor thresholds, the sense of smell is often unreliable for detecting many compounds. There is no correlation between the quality of an odor and its toxicity. Pleasant-smelling compounds are not necessarily less toxic than foul-smelling ones.

1. The warning property assessments found in the table are based on OSHA evaluations. For the purpose of this manual, chemicals described as having *good* warning properties can be detected by smell or irritation at levels below the TLV by most individuals. Chemicals described as having *adequate* warning properties can be detected at air levels near the TLV. Chemicals described as having *poor* warning properties can be detected only at levels significantly above the TLV or not at all.
2. Reported values for odor threshold in the literature vary greatly for many chemicals and are therefore uncertain. These differences make assessments of warning qualities difficult.

D. Thermal-breakdown products. Under fire conditions, many organic substances will break down to other toxic substances. The amounts, kinds, and distribution of breakdown products vary with the fire conditions and are not easily modeled. Information on the likely thermal-decomposition products is included because of their importance in the assessment of health hazards under fire conditions.

1. In general, incomplete combustion of *any* organic material will produce some carbon monoxide (see p 151).
2. The partial combustion of compounds containing sulfur, nitrogen, or phosphorus atoms will also release their oxides (see pp 350, 280, and 213).
3. Compounds with chlorine atoms will release some hydrogen chloride or chlorine (see p 162) when exposed to high heat or fire; some chlorinated compounds may also generate phosgene (p 305).
4. Compounds containing the fluorine atom are similarly likely to break down to yield some hydrogen fluoride (see p 221) and fluorine.
5. Some compounds (eg, polyurethane) that contain an unsaturated carbon-nitrogen bond will release cyanide (see p 177) during their decomposition.
6. Polychlorinated aromatic compounds may yield polychlorinated dibenzodioxins and polychlorinated dibenzofurans (see p 184) when heated.
7. In addition, smoke from a chemical fire is likely to contain large amounts of the volatilized original chemical and still other poorly characterized partial-breakdown products.
8. The thermal-breakdown product information found in Table IV-4 is derived primarily from data found in the literature and the general considerations described immediately above. Aside from the NFPA codes, Table IV-4 does not cover the chemical reactivity or compatibility of substances.

IV. Summary. Table IV-4 provides basic information that describes the potential health hazards associated with exposure to several hundred chemicals. The table is not a comprehensive listing of all the possible health hazards for each chemical. The information compiled here comes from a wide variety of respected sources (see references following table) and focuses on the more likely or commonly reported health effects. Publications from NIOSH, OSHA, ACGIH, the Hazard Evaluation System and Information Service of the State of California, and NFPA; major textbooks in the fields of toxicology and occupational health; and major review articles were the primary sources of the information found here. Refer to the original sources for more complete information. Table IV-4 is intended primarily to guide users in the quick qualitative assessment of common toxic hazards. Its application to specific situations requires skill. Because of the many data gaps in the toxicology literature, exposures should generally be managed conservatively. Contact a regional poison control center ([800] 222-1222) or medical toxicologist for expert assistance in managing specific emergency exposures.

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (Originally conceived and compiled by Frank J. Mycroft, MPH, PhD)

Abbreviations and designations used in this table are defined as follows:

IARC	=	International Agency for Research on Cancer overall classification (see p 527): 1 = known human carcinogen; 2A = probable human carcinogen; 2B = possible human carcinogen; 3 = inadequate data available.
TLV	=	American Conference of Governmental Industrial Hygienists (ACGIH) threshold limit value 8-hour time weighted average (TLV-TWA) air concentration (see p 528): A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; A3 = ACGIH animal carcinogen.
ppm	=	Parts of chemical per million parts of air.
mg/m ³	=	Milligrams of chemical per cubic meter of air.
mppcf	=	Million particles of dust per cubic foot of air.
(C)	=	Ceiling air concentration (TLV-C) that should not be exceeded at any time.
S	=	Skin absorption can be significant route of exposure.
SEN	=	Potential for worker sensitization as a result of dermal contact or inhalation exposure.

NIOSH CA	=	Judged by National Institute for Occupational Safety and Health to be a known or suspected human carcinogen (see p 529).
OSHA CA	=	Regulated by the Occupational Safety and Health Administration as an occupational carcinogen (see p 529).
IDLH	=	Immediately Dangerous to Life or Health air concentration (see p 529).
LEL	=	For this substance, IDLH value is set at 10% of the Lower Explosive Limit.
ERPG	=	Emergency Response Planning Guidelines air concentration values for a 1-hour period of exposure (see p 529).
NFPA Codes	=	National Fire Protection Association hazard classification codes (see p 512 and p 513): 0 (no hazard) <—> 4 (severe hazard)
H	=	Health hazard
F	=	Fire hazard
R	=	Reactivity hazard
Ox	=	Oxidizing agent
W	=	Water-reactive substance

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Acetaldehyde (CAS: 75-07-0): Corrosive; severe burns to eyes and skin may occur. Vapors strongly irritating to eyes and respiratory tract; evidence for adverse effects on fetal development in animals. A carcinogen in test animals (IARC 2B).	25 ppm (C), A3	2000 ppm ERPG-1: 10 ppm ERPG-2: 200 ppm ERPG-3: 1000 ppm	3 4 2	Colorless liquid. Fruity odor and irritation are both adequate warning properties. Vapor pressure is 750 mm Hg at 20°C (68°F). Highly flammable.
Acetic acid (vinegar acid [CAS: 64-19-7]): Concentrated solutions are corrosive; severe burns to eyes and skin may occur. Vapors strongly irritating to eyes and respiratory tract.	10 ppm	50 ppm	3 2 0	Colorless liquid. Pungent, vinegar-like odor and irritation both occur near the TLV and are adequate warning properties. Vapor pressure is 11 mm Hg at 20°C (68°F). Flammable.

Acetic anhydride (CAS: 108-24-7): Corrosive; severe burns to eyes and skin may result. Dermal sensitization has been reported. Vapors highly irritating to eyes and respiratory tract.	5 ppm	200 ppm	3	2	1	Colorless liquid. Odor and irritation both occur below the TLV and are good warning properties. Vapor pressure is 4 mm Hg at 20°C (68°F). Flammable. Evolves heat upon contact with water.
Acetone (dimethyl ketone, 2-propanone [CAS: 67-64-1]): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant at high levels. Eye irritation and headache are common symptoms of moderate overexposure.	500 ppm	2500 ppm [LEL]	1	3	0	Colorless liquid with a sharp, aromatic odor. Eye irritation is an adequate warning property. Vapor pressure is 266 mm Hg at 25°C (77°F). Highly flammable.
Acetonitrile (methyl cyanide, cyanomethane, ethanenitrile [CAS: 75-05-8]): Vapors mildly irritating to eyes and respiratory tract. Inhibits several metabolic enzyme systems. Dermal absorption occurs. Metabolized to cyanide (see p 177); fatalities have resulted. Symptoms include headache, nausea, vomiting, weakness, and stupor. Limited evidence for adverse effects on fetal development in test animals given large doses.	20 ppm, S	500 ppm	2	3	0	Colorless liquid. Ether-like odor, detectable at the TLV, is an adequate warning property. Vapor pressure is 73 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include oxides of nitrogen and cyanide. May be found in products for removing sculptured nails.
Acetophenone (phenyl methyl ketone [CAS: 98-86-2]): Direct contact mildly irritating to eyes and skin. A CNS depressant at high levels.	10 ppm		1	2	0	Widely used in industry (eg, textile coatings).
Acetylene tetrabromide (tetrabromoethane [CAS: 79-27-6]): Direct contact is irritating to eyes and skin. Vapors irritating to eyes and respiratory tract. Dermal absorption occurs. Highly hepatotoxic; liver injury can result from low-level exposures.	1 ppm	8 ppm	3	0	1	Viscous, pale yellow liquid. Pungent, chloroform-like odor. Vapor pressure is less than 0.1 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen bromide and carbonyl bromide.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Acrolein (acrylaldehyde, 2-propenal [CAS: 107-02-8]): Highly corrosive; severe burns to eyes or skin may result. Vapors extremely irritating to eyes, skin, and respiratory tract; pulmonary edema has been reported. Permanent pulmonary function changes may result.	0.1 ppm (C), S	2 ppm ERPG-1: 0.1 ppm ERPG-2: 0.5 ppm ERPG-3: 3 ppm	4 3 3	Colorless to yellow liquid. An unpleasant odor. Eye irritation occurs at low levels and provides a good warning property. Formed in the pyrolysis of many substances. Vapor pressure is 214 mm Hg at 20°C (68°F). Highly flammable.
Acrylamide (propenamide, acrylic amide [CAS: 79-06-1]): Concentrated solutions are slightly irritating. Well absorbed by all routes. A potent neurotoxin causing peripheral neuropathy. Contact dermatitis also reported. Testicular toxicity in test animals. A carcinogen in test animals (IARC 2B).	0.03 mg/m ³ , S, A3	60 mg/m ³	2 2 2	Colorless solid. Vapor pressure is 0.007 mm Hg at 20°C (68°F). Not flammable. Decomposes around 80°C (176°F). Breakdown products include oxides of nitrogen. Monomer used in the synthesis of polyacrylamide plastics.
Acrylic acid (propenoic acid [CAS: 79-10-7]): Corrosive; severe burns may result. Vapors highly irritating to eyes, skin, and respiratory tract. Limited evidence of adverse effects on fetal development at high doses in test animals. Based on structural analogies, compounds containing the acrylate moiety may be carcinogens.	2 ppm, S	ERPG-1: 2 ppm ERPG-2: 50 ppm ERPG-3: 750 ppm	3 2 2	Colorless liquid with characteristic acrid odor. Vapor pressure is 31 mm Hg at 25°C (77°F). Flammable. Inhibitor added to prevent explosive self-polymerization.
Acrylonitrile (cyanoethylene, vinyl cyanide, propenenitrile [CAS: 107-13-1]): Direct contact can be strongly irritating to eyes and skin. Well absorbed by all routes. A CNS depressant at high levels. Metabolized to cyanide (see p 177). Moderate acute overexposure will produce headache, weakness, nausea, and vomiting. Evidence of adverse effects on fetal development at high doses in animals. A carcinogen in test animals with limited epidemiologic evidence for carcinogenicity in humans (IARC 2A).	2 ppm, S, A3 OSHA CA NIOSH CA	85 ppm ERPG-1: 10 ppm ERPG-2: 35 ppm ERPG-3: 75 ppm	4 3 2	Colorless liquid with a mild odor. Vapor pressure is 83 mm Hg at 20°C (68°F). Flammable. Polymerizes rapidly. Thermal-decomposition products include hydrogen cyanide and oxides of nitrogen. Used in the manufacture of ABS and SAN resins.
Aldicarb (CAS: 116-06-3): A potent, carbamate-type cholinesterase inhibitor (see p 291). Well absorbed dermally.				Absorption by fruits has caused human poisonings.

Aldrin (CAS: 309-00-2): Chlorinated insecticide (see p 161). Minor skin irritant. Convulsant. Hepatotoxin. Well absorbed dermally. Limited evidence for carcinogenicity in test animals (IARC 3).	0.25 mg/m ³ , S, A3 NIOSH CA	25 mg/m ³				Tan to dark brown solid. A mild chemical odor. Vapor pressure is 0.000006 mm Hg at 20°C (68°F). Not flammable but breaks down, yielding hydrogen chloride gas. Most uses have been banned in US.
Allyl alcohol (2-propen-1-ol [CAS: 107-18-6]): Strongly irritating to eyes and skin; severe burns may result. Vapors highly irritating to eyes and respiratory tract. Systemic poisoning can result from dermal exposures. May cause liver and kidney injury.	0.5 ppm, S	20 ppm	4	3	1	Colorless liquid. Mustard-like odor and irritation occur near the TLV and serve as good warning properties. Vapor pressure is 17 mm Hg at 20°C (68°F). Flammable. Used in chemical synthesis and as a pesticide.
Allyl chloride (3-chloro-1-propene [CAS: 107-05-1]): Highly irritating to eyes and skin. Vapors highly irritating to eyes and respiratory tract. Well absorbed by the skin, producing both superficial and penetrating irritation and pain. Causes liver and kidney injury in test animals. Chronic exposures have been associated with reports of mild neuropathy.	1 ppm, A3	250 ppm ERPG-1: 3 ppm ERPG-2: 40 ppm ERPG-3: 300 ppm	3	3	1	Colorless, yellow, or purple liquid. Pungent, disagreeable odor and irritation occur only at levels far above the TLV. Vapor pressure is 295 mm Hg at 20°C (68°F). Highly flammable. Breakdown products include hydrogen chloride and phosgene.
Allyl glycidyl ether (AGE [CAS: 106-92-3]): Highly irritating to eyes and skin; severe burns may result. Vapors irritating to eyes and respiratory tract. Sensitization dermatitis has been reported. Hematopoietic and testicular toxicity occurs in test animals at modest doses. Well absorbed through the skin.	1 ppm	50 ppm				Colorless liquid. Unpleasant odor. Vapor pressure is 2 mm Hg at 20°C (68°F). Flammable.
Allyl propyl disulfide (onion oil [CAS: 2179-59-1]): Mucous membrane irritant and lacrimator.	2 ppm					Liquid with a pungent, irritating odor. A synthetic flavorant and food additive. Thermal-breakdown products include sulfur oxide fumes.
α-Alumina (aluminum oxide [CAS: 1344-28-1]): Nuisance dust and physical irritant.	10 mg/m ³					

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <— 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Aluminum metal (CAS: 7429-90-5): Dusts can cause mild eye and respiratory tract irritation. Long-term inhalation of large amounts of fine aluminum powders or fumes from aluminum ore (bauxite) has been associated with reports of pulmonary fibrosis (Shaver's disease). Acute exposures in aluminum refining ("pot room") has been associated with asthma-like responses. Industrial processes used to produce aluminum have been associated with an increased incidence of cancer in workers.	10 mg/m ³ (metal and oxide) 5 mg/m ³ (pyrophoric powders, welding fumes) 2 mg/m ³ (soluble salts, alkyls NOC)		0 3 1 (powder)	Oxidizes readily. Fine powders and flakes are flammable and explosive when mixed with air. Reacts with acids and caustic solutions to produce flammable hydrogen gas.
Aluminum phosphide (CAS: 20859-73-8): Effects caused by phosphine gas that is produced on contact with moisture. Severe respiratory tract irritant. See phosphides, p 306.			4 4 2 W	Used as a structural fumigant as dry powder or pellet, similar to zinc phosphide.
4-Aminodiphenyl (<i>p</i>-aminobiphenyl, <i>p</i>-phenylaniline [CAS: 92-67-1]): Potent bladder carcinogen in humans (IARC 1). Causes methemoglobinemia (see p 261).	S, A1 OSHA CA NIOSH CA			Colorless crystals.
2-Aminopyridine (CAS: 504-29-0): Mild irritant. Potent CNS convulsant. Very well absorbed by inhalation and skin contact. Signs and symptoms include headache, dizziness, nausea, elevated blood pressure, and convulsions.	0.5 ppm	5 ppm		Colorless solid with a distinctive odor and a very low vapor pressure at 20°C (68°F). Combustible.
Amitrole (3-amino-1,2,4-triazole [CAS: 61-82-5]): Mild irritant. Well absorbed by inhalation and skin contact. Shows antithyroid activity in test animals. Evidence of adverse effects on fetal development in test animals at high doses. A carcinogen in test animals (IARC 2B).	0.2 mg/m ³ , A3			Crystalline solid. Appearance and some hazardous properties vary with the formulation.

Ammonia (CAS: 7664-41-7): Corrosive; severe burns to eyes and skin result. Vapors highly irritating to eyes and respiratory tract; pulmonary edema has been reported. Severe responses are associated with anhydrous ammonia or with concentrated ammonia solutions (see p 70).	25 ppm	300 ppm ERPG-1: 25 ppm ERPG-2: 150 ppm ERPG-3: 750 ppm	3 1 0	Colorless gas or aqueous solution. Pungent odor and irritation are good warning properties. Anhydrous ammonia is flammable. Breakdown products include oxides of nitrogen. Although widely used in industry, concentrated forms are most frequently encountered in agriculture and from its use as a refrigerant.
<i>n</i>-Amyl acetate (CAS: 628-63-7): Defats the skin, producing a dermatitis. Vapors mildly irritating to eyes and respiratory tract. A CNS depressant at very high levels. Reversible liver and kidney injury may occur at very high exposures.	100 ppm	1000 ppm	1 3 0	Colorless liquid. Its banana-like odor detectable below the TLV is a good warning property. Vapor pressure is 4 mm Hg at 20°C (68°F). Flammable.
<i>sec</i>-Amyl acetate (α-methylbutyl acetate [CAS: 628-38-0]): Defats the skin, producing a dermatitis. Vapors irritating to eyes and respiratory tract. A CNS depressant at very high levels. Reversible liver and kidney injury may occur at high-level exposures.	125 ppm	1000 ppm	1 3 0	Colorless liquid. A fruity odor occurs below the TLV and is a good warning property. Vapor pressure is 7 mm Hg at 20°C (68°F). Flammable.
Aniline (aminobenzene, phenylamine [CAS: 62-53-3]): Mildly irritating to eyes upon direct contact, with corneal injury possible. Potent inducer of methemoglobinemia (see p 261). Well absorbed via inhalation and dermal routes. Limited evidence of carcinogenicity in test animals (IARC 3).	2 ppm, S, A3	100 ppm	3 2 0	Colorless to brown viscous liquid. Distinctive amine odor and mild eye irritation occur well below the TLV and are good warning properties. Vapor pressure is 0.6 mm Hg at 20°C (68°F). Combustible. Breakdown products include oxides of nitrogen.
<i>o</i>-Anisidine (<i>o</i>-methoxyaniline [CAS: 29191-52-4]): Mild skin sensitizer causing dermatitis. Causes methemoglobinemia (see p 261). Well absorbed through skin. Headaches and vertigo are signs of exposure. Possible liver and kidney injury. A carcinogen in test animals (IARC 2B).	0.5 mg/m ³ , S, A3	50 mg/m ³	2 1 0	Colorless, red, or yellow liquid with the fishy odor of amines. Vapor pressure is less than 0.1 mm Hg at 20°C (68°F). Combustible. Primarily used in the dye-stuffs industry.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) \longleftrightarrow 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Antimony and salts (antimony trichloride, antimony trioxide, antimony pentachloride [CAS: 7440-36-0]): Dusts and fumes irritating to eyes, skin, and respiratory tract. Toxicity through contamination with silica or arsenic may occur. Antimony trioxide is carcinogenic in test animals with limited evidence for carcinogenicity among antimony trioxide production workers (IARC 2B). See also p 98.	0.5 mg/m ³ (as Sb)	50 mg/m ³ (as Sb)	3 0 1 (SbCl ₅) 4 0 1 (SbF ₅)	The metal is silver-white and has a very low vapor pressure. Some chloride salts release HCl upon contact with air.
ANTU (α-naphthylthiourea [CAS: 86-88-4]): Well absorbed by skin contact and inhalation. Pulmonary edema and liver injury may result from ingestion. Repeated exposures can injure the thyroid and adrenals, producing hypothyroidism. Possible slight contamination with alpha-2-naphthylamine, a human bladder carcinogen.	0.3 mg/m ³	100 mg/m ³		Colorless to gray solid powder. Odorless. A rodenticide. Breakdown products include oxides of nitrogen and sulfur dioxide.
Arsenic (CAS: 7440-38-2): Irritating to eyes and skin; hyperpigmentation, hyperkeratoses, and skin cancers have been described. A general cellular poison. May cause bone marrow suppression, peripheral neuropathy, and gastrointestinal, liver, and cardiac injury. Some arsenic compounds have adverse effects on fetal development in test animals. Exposure linked to skin, respiratory tract, and liver cancer in workers (IARC 1). See also p 115.	0.01 mg/m ³ (as As) A1 OSHA CA NIOSH CA	5 mg/m ³ (as As)		Elemental forms vary in appearance. Crystals are gray. Amorphous forms may be yellow or black. Vapor pressure is very low—about 1 mm Hg at 372°C (701°F).
Arsine (CAS: 7784-42-1): Extremely toxic hemolytic agent. Symptoms include abdominal pain, jaundice, hemoglobinuria, and renal failure. Low-level chronic exposures reported to cause anemia. See also p 119.	0.05 ppm NIOSH CA	3 ppm ERPG-2: 0.5 ppm ERPG-3: 1.5 ppm	4 4 2	Colorless gas with an unpleasant garlic-like odor. Flammable. Breakdown products include arsenic trioxide and arsenic fumes. Used in the semiconductor industry.
Asbestos (chrysotile, amosite, crocidolite, tremolite, anthophyllite): Effects of exposure include asbestosis (fibrosis of the lung), lung cancer, mesothelioma, and possible digestive tract cancer (IARC 1). Signs of toxicity are usually delayed at least 15–30 years. See also p 121.	0.1 fibers/cm ³ , A1 OSHA CA NIOSH CA			Fibrous materials. Not combustible. TLVs vary with type: amosite, 0.5 fibers/cm ³ , A1; chrysotile, 2 fibers/cm ³ , A1; crocidolite, 0.2 fibers/cm ³ , A1; other forms, 2 fibers/cm ³ , A1.

Asphalt fumes (CAS: 8052-42-4): Vapors and fumes irritating to eyes, skin, and respiratory tract. Skin contact can produce hyperpigmentation, dermatitis, or photosensitization. Some constituents are carcinogenic in test animals.	0.5 mg/m ³			Smoke with an acrid odor. Asphalt is a complex mixture of paraffinic, aromatic, and heterocyclic hydrocarbons formed by the evaporation of lighter hydrocarbons from petroleum and the partial oxidation of the residue.
Atrazine (CAS: 1912-24-9): A triazine herbicide. Minor skin and eye irritant.	5 mg/m ³			
Azinphos-methyl (Guthion [CAS: 86-50-0]: Low-potency organophosphate anticholinesterase insecticide (see p 291). Requires metabolic activation.	0.2 mg/m ³ , S, SEN	10 mg/m ³		Brown waxy solid with a negligible vapor pressure. Not combustible. Breakdown products include sulfur dioxide, oxides of nitrogen, and phosphoric acid.
Barium and soluble compounds (CAS: 7440-39-3): Powders irritating to eyes, skin, and respiratory tract. Although not typical of workplace exposures, ingestion of soluble barium salts (as opposed to the insoluble medical compounds used in radiography) are associated with muscle paralysis. See also p 127.	0.5 mg/m ³ (as Ba)	50 mg/m ³ (as Ba)		Most soluble barium compounds (eg, barium chloride, barium carbonate) are odorless white solids. Elemental barium spontaneously ignites on contact with air and reacts with water to form flammable hydrogen gas.
Benomyl (methyl 1-[butylcarbamoyl]-2-benzimidazolecarbamate, Benlate [CAS: 17804-35-2]): A carbamate cholinesterase inhibitor (see p 291). Mildly irritating to eyes and skin. Of low systemic toxicity in test animals by all routes. Evidence of adverse effects on fetal development in test animals.	10 mg/m ³			White crystalline solid with a negligible vapor pressure at 20°C (68°F). Fungicide and miticide. Appearance and some hazardous properties vary with the formulation.
Benzene (CAS: 71-43-2): Vapors mildly irritating to eyes and respiratory tract. Well absorbed by all routes. A CNS depressant at high levels. Symptoms include headache, nausea, tremors, cardiac arrhythmias, and coma. Chronic exposure may result in hematopoietic system depression, aplastic anemia, and leukemia (IARC 1). See also p 128.	0.5 ppm, A1, S OSHA CA NIOSH CA	500 ppm ERPG-1: 50 ppm ERPG-2: 150 ppm ERPG-3: 1000 ppm	2 3 0	Colorless liquid. Aromatic hydrocarbon odor. Vapor pressure is 75 mm Hg at 20°C (68°F). Flammable.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Benzidine (<i>p</i>-diaminodiphenyl [CAS: 92-87-5]): Extremely well absorbed by inhalation and through skin. Causes bladder cancer in exposed workers (IARC 1).	S, A1 OSHA CA NIOSH CA			White or reddish solid crystals. Breakdown products include oxides of nitrogen. Found in dye-stuffs, rubber industry, and analytical laboratories.
Benzoyl peroxide (CAS: 94-36-0): Dusts cause skin, eye, and respiratory tract irritation. A skin sensitizer.	5 mg/m ³	1500 mg/m ³		White granules or crystalline solids with a very faint odor. Vapor pressure is negligible at 20°C (68°F). Strong oxidizer, reacting with combustible materials. Decomposes at 75°C (167°F). Unstable and explosive at high temperatures.
Benzyl chloride (α-chlorotoluene, [chloro-methyl]benzene [CAS: 100-44-7]): Highly irritating to skin and eyes. A potent lacrimator. Vapors highly irritating to respiratory tract. Symptoms include weakness, headache, and irritability. May injure liver. Limited evidence for carcinogenicity and adverse effects on fetal development in test animals.	1 ppm, A3	10 ppm ERPG-1: 1 ppm ERPG-2: 10 ppm ERPG-3: 25 ppm	3 2 1	Colorless liquid with a pungent odor. Vapor pressure is 0.9 mm Hg at 20°C (68°F). Combustible. Breakdown products include phosgene and hydrogen chloride.
Beryllium (CAS: 7440-41-7): Very high acute exposure to dusts and fumes cause eye, skin, and respiratory tract irritation. However, more importantly, chronic low-level exposures to beryllium oxide dusts can produce interstitial lung disease called berylliosis, which is a sarcoid-like condition that can have extrapulmonary manifestations. A carcinogen in test animals. There is limited evidence of carcinogenicity in humans (IARC 1).	0.002 mg/m ³ , A1 NIOSH CA	4 mg/m ³ (as Be) ERPG-2: 25 µg/m ³ ERPG-3: 100 µg/m ³	3 1 0	Silver-white metal or dusts. Reacts with some acids to produce flammable hydrogen gas. Exposures have occurred in nuclear and aerospace workers; may be present in any specialty metal alloy manufacturing process.
Biphenyl (diphenyl [CAS: 92-52-4]): Fumes mildly irritating to eyes. Chronic overexposures can cause bronchitis and liver injury. Peripheral neuropathy and CNS injury have also been reported.	0.2 ppm	100 mg/m ³	2 1 0	White crystals. Unusual but pleasant odor. Combustible.

Borates (anhydrous sodium tetraborate, borax [CAS: 1303-96-4]): Contact with dusts is highly irritating to eyes, skin, and respiratory tract. Contact with tissue moisture may cause thermal burns because hydration of borates generates heat. See also p 135.

1 mg/m³
(anhydrous and
pentahydrate)
5 mg/m³
(decahydrate)

White or light gray solid crystals. Odorless.

Boron oxide (boric anhydride, boric oxide [CAS: 1303-86-2]): Contact with moisture generates boric acid (see p 135). Direct eye or skin contact with dusts is irritating. Occupational inhalation exposure has caused sore throat and cough. Evidence for adverse effects on the testes in test animals.

10 mg/m³

2000 mg/m³

Colorless glassy granules, flakes, or powder. Odorless. Not combustible.

Boron tribromide (CAS: 10294-33-4): Corrosive; decomposed by tissue moisture to hydrogen bromide (see p 140) and boric acid (see p 135). Severe skin and eye burns may result from direct contact. Vapors highly irritating to eyes and respiratory tract.

1 ppm (C)

3 0 2
W

Colorless fuming liquid. Reacts with water, forming hydrogen bromide and boric acid. Vapor pressure is 40 mm Hg at 14°C (57°F).

Boron trifluoride (CAS: 7637-07-2): Corrosive; decomposed by tissue moisture to hydrogen fluoride (see p 221) and boric acid (see p 135). Severe skin and eye burns may result. Vapors highly irritating to eyes, skin, and respiratory tract.

1 ppm (C)

25 ppm
ERPG-1: 2 ppm
ERPG-2: 30 ppm
ERPG-3: 100 ppm

4 0 1

Colorless gas. Dense white irritating fumes produced on contact with moist air. These fumes contain boric acid and hydrogen fluoride.

Bromine (CAS: 7726-95-6): Corrosive; severe skin and eye burns may result. Vapors highly irritating to eyes and respiratory tract; pulmonary edema may result. Measles-like eruptions may appear on the skin several hours after a severe exposure.

0.1 ppm

3 ppm
ERPG-1: 0.1 ppm
ERPG-2: 0.5 ppm
ERPG 3: 5 ppm

3 0 0
Ox

Heavy red-brown fuming liquid. Odor and irritation thresholds are below the TLV and are adequate warning properties. Vapor pressure is 175 mm Hg at 20°C (68°F). Not combustible. Used as an alternative to chlorine in water purification (eg, hot tubs).

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <— 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Bromine pentafluoride (CAS: 7789-30-2): Corrosive; severe skin and eye burns may result. Vapors extremely irritating to eyes and respiratory tract. Chronic overexposures caused severe liver and kidney injury in test animals.	0.1 ppm		4 0 3 W, Ox	Pale yellow liquid. Pungent odor. Not combustible. Highly reactive, igniting most organic materials and corroding many metals. Highly reactive with acids. Breakdown products include bromine and fluorine.
Bromoform (tribromomethane [CAS: 75-25-2]): Vapors highly irritating to eyes and respiratory tract. Well absorbed by inhalation and skin contact. CNS depressant. Liver and kidney injury may occur. Two preliminary tests indicate that it may be an animal carcinogen.	0.5 ppm, S, A3	850 ppm		Colorless to yellow liquid. Chloroform-like odor and irritation are adequate warning properties. Vapor pressure is 5 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen bromide and bromine.
1,3-Butadiene (CAS: 106-99-0): Vapors mildly irritating. A CNS depressant at very high levels. Evidence of adverse effects on reproductive organs and fetal development in test animals. A very potent carcinogen in test animals; evidence of carcinogenicity in exposed workers (IARC 2A).	2 ppm, A2 NIOSH CA	2000 ppm [LEL] ERPG-1: 10 ppm ERPG-2: 200 ppm ERPG-3: 5000 ppm	2 4 2	Colorless gas. Mild aromatic odor is a good warning property. Readily polymerizes. Inhibitor added to prevent peroxide formation. Used in the formation of styrene-butadiene and ABS plastics.
2-Butoxyethanol (ethylene glycol monobutyl ether, butyl Cellosolve [CAS: 111-76-2]): Liquid very irritating to eyes and slightly irritating to skin. Vapors irritating to eyes and respiratory tract. Mild CNS depressant. A hemolytic agent in test animals. Well absorbed dermally. Liver and kidney toxicity in test animals. Reproductive toxicity much less than certain other glycol ethers such as ethylene glycol monomethyl ether. See also p 194.	25 ppm, S [proposed: 20 ppm]	700 ppm		Colorless liquid with a mild ether-like odor. Irritation occurs below the TLV and is a good warning property. Vapor pressure is 0.6 mm Hg at 20°C (68°F). Flammable.
n-Butyl acetate (CAS: 123-86-4): Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels. Limited evidence for adverse effects on fetal development in test animals.	150 ppm	1700 ppm [LEL] ERPG-1: 5 ppm ERPG-2: 200 ppm ERPG-3: 3000 ppm	1 3 0	Colorless liquid. Fruity odor is a good warning property. Vapor pressure is 10 mm Hg at 20°C (68°F). Flammable.

sec-Butyl acetate (2-butanol acetate [CAS: 105-46-4]): Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels.	200 ppm	1700 ppm [LEL]	1 3 0	
tert-Butyl acetate (tert-butyl ester of acetic acid [CAS: 540-88-5]): Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels.	200 ppm	1500 ppm [LEL]		
n-Butyl acrylate (CAS: 141-32-2): Highly irritating to skin and eyes; corneal necrosis may result. Vapors highly irritating to eyes and respiratory tract. Based on structural analogies, compounds containing the acrylate moiety may be carcinogens (IARC 3).	2 ppm	ERPG-1: 0.05 ppm ERPG-2: 25 ppm ERPG-3: 250 ppm	2 2 2	Colorless liquid. Vapor pressure is 3.2 mm Hg at 20°C (68°F). Flammable. Contains inhibitor to prevent polymerization.
n-Butyl alcohol (CAS: 71-36-3): Irritating upon direct contact. Vapors mildly irritating to eyes and respiratory tract. A CNS depressant at very high levels. Chronic occupational overexposures associated with hearing loss and vestibular impairment.	50 ppm (C), S [proposed: 25 ppm (C)]	1400 ppm [LEL]	1 3 0	Colorless liquid. Strong odor and irritation occur below the TLV and are both good warning properties. Flammable.
sec-Butyl alcohol (CAS: 78-92-2): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant at high levels.	100 ppm	2000 ppm	1 3 0	Colorless liquid. Pleasant odor occurs well below the TLV and is an adequate warning property. Vapor pressure is 13 mm Hg at 20°C (68°F). Flammable.
tert-Butyl alcohol (CAS: 75-65-0): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant at high levels.	100 ppm	1600 ppm	1 3 0	Colorless liquid. Camphor-like odor and irritation occur slightly below the TLV and are good warning properties. Vapor pressure is 31 mm Hg at 20°C (68°F). Flammable.
Butylamine (CAS: 109-73-9): Caustic alkali. Liquid highly irritating to eyes and skin upon direct contact; severe burns may result. Vapors highly irritating to eyes and respiratory tract. May cause histamine release.	5 ppm (C), S	300 ppm	3 3 0	Colorless liquid. Ammonia or fish-like odor occurs below the TLV and is an adequate warning property. Vapor pressure is about 82 mm Hg at 20°C (68°F). Flammable.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <— 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
<i>tert</i>-Butyl chromate (CAS: 1189-85-1): Liquid highly irritating to eyes and skin; severe burns may result. Vapors or mists irritating to eyes and respiratory tract. A liver and kidney toxin. By analogy to other Cr(VI) compounds, a possible carcinogen. See also p 167.	0.1 mg/m ³ (C) (as CrO ₃) NIOSH CA S	15 mg/m ³ (as Cr VI)		Liquid. Reacts with moisture.
<i>n</i>-Butyl glycidyl ether (BGE, glycidylbutylether, 1,2-epoxy-3-butoxy propane (CAS: 2426-08-6)): Liquid irritating to eyes and skin. Vapors irritating to the respiratory tract. A CNS depressant. Causes sensitization dermatitis upon repeated exposures. Testicular atrophy and hematopoietic injury at modest doses in test animals.	25 ppm	250 ppm		Colorless liquid. Vapor pressure is 3 mm Hg at 20°C (68°F).
<i>n</i>-Butyl lactate (CAS: 138-22-7): Vapors irritating to eyes and respiratory tract. Workers have complained of sleepiness, headache, coughing, nausea, and vomiting.	5 ppm		1 2 0	Colorless liquid. Vapor pressure is 0.4 mm Hg at 20°C (68°F). Combustible.
<i>n</i>-Butyl mercaptan (butanethiol (CAS: 109-79-5)): Vapors mildly irritating to eyes and respiratory tract. Pulmonary edema occurred at high exposure levels in test animals. A CNS depressant at very high levels. Limited evidence for adverse effects on fetal development in test animals at high doses.	0.5 ppm	500 ppm	2 3 0	Colorless liquid. Strong, offensive garlic-like odor. Vapor pressure is 35 mm Hg at 20°C (68°F). Flammable.
<i>o</i>-sec-Butylphenol (CAS: 89-72-5): Irritating to skin upon direct, prolonged contact; burns have resulted. Vapors mildly irritating to eyes and respiratory tract.	5 ppm, S			A liquid.
<i>p</i>-tert-Butyltoluene (CAS: 98-51-1): Mild skin irritant upon direct contact. Defatting agent causing dermatitis. Vapors irritating to eyes and respiratory tract. A CNS depressant. Limited evidence of adverse effects on fetal development in test animals at high doses.	1 ppm	100 ppm		Colorless liquid. Gasoline-like odor and irritation occur below the TLV and are both good warning properties. Vapor pressure is less than 1 mm Hg at 20°C (68°F). Combustible.

Cadmium and compounds: Acute fumes and dust exposures can injure the respiratory tract; pulmonary edema can occur. Chronic exposures associated primarily with kidney injury and lung injury. Adverse effects on the testes and on fetal development in test animals. Cadmium and some of its compounds are carcinogenic in test animals. Limited direct evidence for carcinogenicity in humans (IARC 2A). See also p 141.

0.01 mg/m³
(total dust, as Cd)
0.002 mg/m³
(respirable dust, as Cd)
A2
NIOSH CA

9 mg/m³
(dust and fumes, as Cd)

Compounds vary in color. Give off fumes when heated or burned. Generally poor warning properties. Metal has a vapor pressure of about 1 mm Hg at 394°C (741°F) and reacts with acids to produce flammable hydrogen gas.

Calcium cyanamide (calcium carbimide, lime nitrogen [CAS: 156-62-7]): Dusts highly irritating to eyes, skin, and respiratory tract. Causes sensitization dermatitis. Systemic symptoms include nausea, fatigue, headache, chest pain, and shivering. A disulfiram-like interaction with alcohol (see p 186); “cyanamide flush,” may occur in exposed workers. See also cadmium, p 141.

0.5 mg/m³

Gray crystalline material. Reacts with water, generating ammonia and flammable acetylene.

Calcium hydroxide (hydrated lime, caustic lime [CAS: 1305-62-0]): Corrosive (see p 157); severe eye and skin burns may result. Dusts moderately irritating to eyes and respiratory tract.

5 mg/m³

White, deliquescent crystalline powder. Odorless.

Calcium oxide (lime, quicklime, burnt lime [CAS: 1305-78-8]): Corrosive (see p 157). Exothermic reactions with moisture. Highly irritating to eyes and skin upon direct contact. Dusts highly irritating to skin, eyes, and respiratory tract.

2 mg/m³

25 mg/m³

3 0 1

White or gray solid powder. Odorless. Hydration generates heat.

Camphor, synthetic (CAS: 76-22-2): Irritating to eyes and skin upon direct contact. Vapors irritating to eyes and nose; may cause loss of sense of smell. A convulsant at doses typical of overdose ingestion, rather than industrial exposure. See also p 147.

2 ppm

200 mg/m³

0 2 0

Colorless glassy solid. Sharp, obnoxious, aromatic odor near the TLV is an adequate warning property. Vapor pressure is 0.18 mm Hg at 20°C (68°F). Combustible.

Caprolactam (CAS: 105-60-2): Highly irritating to eyes and skin upon direct contact. Vapors, dusts, and fumes highly irritating to eyes and respiratory tract. Convulsant activity in test animals.

1 mg/m³ (dust)
5 ppm (vapor)
[proposed: 5 mg/m³
(aerosol and vapor)]

White solid crystals. Unpleasant odor. Vapor pressure is 6 mm Hg at 120°C (248°F). Thermal-breakdown products include oxides of nitrogen.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Captafol (Difolatan [CAS: 2425-06-1]): Dusts irritating to eyes, skin, and respiratory tract. A skin and respiratory tract sensitizer. May cause photoallergic dermatitis. Evidence for carcinogenicity in animal tests (IARC 2A).	0.1 mg/m ³ , S			White solid crystals. Distinctive, pungent odor. Fungicide. Thermal-breakdown products include hydrogen chloride and oxides of nitrogen or sulfur.
Carbaryl (1-naphthyl <i>N</i>-methylcarbamate, Sevin [CAS: 63-25-2]): A carbamate-type cholinesterase inhibitor (see p 291). Evidence of adverse effects on fetal development in test animals at high doses.	5 mg/m ³	100 mg/m ³		Colorless, white or gray solid. Odorless. Vapor pressure is 0.005 mm Hg at 20°C (68°F). Breakdown products include oxides of nitrogen and methylamine.
Carbofuran (2,3-dihydro-2,2'-dimethyl-7-benzofuranylmethylcarbamate, Furadan [CAS: 1563-66-2]): A carbamate-type cholinesterase inhibitor (see p 291). Not well absorbed by skin contact.	0.1 mg/m ³			White solid crystals. Odorless. Vapor pressure is 0.00005 mm Hg at 33°C (91°F). Thermal-breakdown products include oxides of nitrogen.
Carbon black (CAS: 1333-86-4): Causes eye and respiratory irritation. A lung carcinogen in test animals (IARC 2B).	3.5 mg/m ³ NIOSH CA			Extremely fine powdery forms of elemental carbon; may have adsorbed polycyclic organic hydrocarbons.
Carbon disulfide (CAS: 75-15-0): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant causing coma at high concentrations. Well absorbed by all routes. Acute symptoms include headache, dizziness, nervousness, and fatigue. Neuropathies, parkinsonian-like syndromes, and psychosis may occur. A liver and kidney toxin. An atherogenic agent causing stroke and heart disease. Adversely affects male and female reproductive systems in test animals and humans. Evidence for adverse effects on fetal development in test animals. See also p 150.	10 ppm, S	500 ppm ERPG-1: 1 ppm ERPG-2: 50 ppm ERPG-3: 500 ppm	3 3 0	Colorless to pale yellow liquid. Disagreeable odor occurs below the TLV and is a good warning property. Vapor pressure is 300 mm Hg at 20°C (68°F). Highly flammable. Major use in viscose rayon manufacture but is also used in chemical synthesis and as an industrial solvent.

Carbon monoxide (CAS: 630-08-0): Binds to hemoglobin, forming carboxyhemoglobin and causing cellular hypoxia. Persons with heart disease are more susceptible. Signs and symptoms include headache, dizziness, coma, and convulsions. Permanent CNS impairment and adverse effects on fetal development may occur after severe poisoning. See also p 151.	25 ppm	1200 ppm ERPG-1: 200 ppm ERPG-2: 350 ppm ERPG-3: 500 ppm	3 4 0	Colorless, odorless gas. No warning properties. Important sources of exposure include indoor use of internal combustion engines, structural fires, and faulty space heaters.
Carbon tetrabromide (tetrabromomethane [CAS: 558-13-4]): Highly irritating to eyes upon direct contact. Vapors highly irritating to eyes and respiratory tract. The liver and kidneys are also likely target organs.	0.1 ppm			White to yellow-brown solid. Vapor pressure is 40 mm Hg at 96°C (204°F). Nonflammable; thermal-breakdown products may include hydrogen bromide and bromine.
Carbon tetrachloride (tetrachloromethane [CAS 56-23-5]): Mildly irritating upon direct contact. A CNS depressant. May cause cardiac arrhythmias. Highly toxic to kidney and liver. Alcohol abuse increases risk of liver toxicity. A carcinogen in test animals (IARC 2B). See also p 154.	5 ppm, S, A2 NIOSH CA	200 ppm ERPG-1: 20 ppm ERPG-2: 100 ppm ERPG-3: 750 ppm	3 0 0	Colorless. Ether-like odor is a poor warning property. Vapor pressure is 91 mm Hg at 20°C (68°F). Not combustible. Breakdown products include hydrogen chloride, chlorine gas, and phosgene.
Carbonyl fluoride (COF₂ [CAS: 353-50-41]): Extremely irritating to eyes and respiratory tract; pulmonary edema may result. Toxicity results from its hydrolysis to hydrofluoric acid (see p 221).	2 ppm			Colorless, odorless gas. Decomposes upon contact with water to produce hydrofluoric acid.
Catechol (1,2-benzenediol [CAS: 120-80-9]): Highly irritating upon direct contact; severe eye and deep skin burns result. Well absorbed by skin. Systemic toxicity similar to that of phenol (see p 302); however, catechol may be more likely to cause convulsions and hypertension. At high doses, renal and liver injury may occur.	5 ppm, S, A3			Colorless solid crystals.
Cesium hydroxide (cesium hydrate [CAS: 21351-79-1]): Corrosive (see p 157). Highly irritating upon direct contact; severe burns may result. Dusts are irritating to eyes and respiratory tract.	2 mg/m ³			Colorless or yellow crystals that absorb moisture. Negligible vapor pressure.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Chlordane (CAS: 57-74-9): Irritating to skin. A CNS convulsant. Skin absorption is rapid and has caused convulsions and death. Hepatotoxic. Evidence of carcinogenicity in test animals (IARC 2B). See also p 161.	0.5 mg/m ³ , S, A3	100 mg/m ³		Viscous amber liquid. Formulations vary in appearance. A chlorine-like odor. Vapor pressure is 0.00001 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen chloride, phosgene, and chlorine gas. EPA banned this insecticide in 1976.
Chlorinated camphene (toxaphene [CAS: 8001-35-2]): Moderately irritating upon direct contact. A CNS convulsant. Acute symptoms include nausea, confusion, tremors, and convulsions. Well absorbed by skin. Potential liver and kidney injury. See also p 161.	0.5 mg/m ³ , S, A3	200 mg/m ³		Waxy amber-colored solid. Formulations vary in appearance. Turpentine-like odor. Vapor pressure is about 0.3 mm Hg at 20°C (68°F). Pesticide use banned in the US since 1990.
Chlorinated diphenyl oxide (CAS: 55720-99-5): Chloracne may result from even small exposures. A hepatotoxin in chronically exposed test animals. Signs and symptoms include gastrointestinal upset, jaundice, and fatigue.	0.5 mg/m ³	5 mg/m ³		Waxy solid or liquid. Vapor pressure is 0.00006 mm Hg at 20°C (68°F).
Chlorine (CAS: 7782-50-5): Extremely irritating to eyes, skin, and respiratory tract; severe burns and pulmonary edema may occur. Symptoms include lacrimation, sore throat, headache, coughing, and wheezing. High concentrations may cause rapid tissue swelling and airway obstruction through laryngeal edema. See also p 162.	0.5 ppm	10 ppm ERPG-1: 1 ppm ERPG-2: 3 ppm ERPG-3: 20 ppm	4 0 0 Ox	Amber liquid or greenish-yellow gas. Irritating odor and irritation occur near the TLV and are both good warning properties. Can be formed when acid cleaners are mixed with hypochlorite bleach cleaners.
Chlorine dioxide (chlorine peroxide [CAS: 10049-04-4]): Extremely irritating to eyes and respiratory tract. Symptoms and signs are those of chlorine gas above (see p 162).	0.1 ppm	5 ppm ERPG-2: 0.5 ppm ERPG-3: 3 ppm		Yellow-green or orange gas or liquid. Sharp odor at the TLV is a good warning property. Reacts with water to produce perchloric acid. Decomposes explosively in sunlight, with heat, or with shock to produce chlorine gas. Bleaching agent widely used in paper industry.

Chlorine trifluoride (chlorine fluoride [CAS: 7790-91-2]): Upon contact with moist tissues, hydrolyzes to chlorine (see p 162), hydrogen fluoride (see p 221), and chlorine dioxide. Extremely irritating to eyes, skin, and respiratory tract; severe burns or delayed pulmonary edema could result.	0.1 ppm (C)	20 ppm ERPG-1: 0.1 ppm ERPG-2: 1 ppm ERPG-3: 10 ppm	4 0 3 W, Ox	Greenish-yellow or colorless liquid or gas, or white solid. Possesses a suffocating, sweet odor. Not combustible. Water-reactive, yielding hydrogen fluoride and chlorine gas. Used as incendiary and rocket fuel additive.
Chloroacetaldehyde (CAS: 107-20-0): Extremely corrosive upon direct contact; severe burns will result. Vapors extremely irritating to eyes, skin, and respiratory tract.	1 ppm (C)	45 ppm		Colorless liquid with a pungent, irritating odor. Vapor pressure is 100 mm Hg at 20°C (68°F). Combustible. Readily polymerizes. Thermal-breakdown products include phosgene and hydrogen chloride.
α-Chloroacetophenone (tear gas, chemical Mace [CAS: 532-27-4]): Extremely irritating to mucous membranes and respiratory tract. With extremely high inhalational exposures, lower respiratory injury is possible. A potent skin sensitizer. See also p 213.	0.05 ppm	15 mg/m ³	2 1 0	Sharp, irritating odor and irritation occur near the TLV and are adequate warning properties. Vapor pressure is 0.012 mm Hg at 20°C (68°F). Mace is a common crowd control agent.
Chlorobenzene (monochlorobenzene [CAS: 108-90-7]): Irritating; skin burns may result from prolonged contact. Vapors irritating to eyes and respiratory tract. A CNS depressant. May cause methemoglobinemia (see p 261). Prolonged exposure to high levels has caused lung, liver, and kidney injury in test animals.	10 ppm, A3	1000 ppm	2 3 0	Colorless liquid. Aromatic odor occurs below the TLV and is a good warning property. Vapor pressure is 8.8 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include hydrogen chloride and phosgene.
o-Chlorobenzylidene malononitrile (tear gas, OCBM, CS [CAS: 2698-41-1]): Highly irritating on direct contact; severe burns may result. Aerosols and vapors very irritating to mucous membranes and upper respiratory tract. With extremely high inhalational exposures, lower respiratory injury is possible. Potent skin sensitizer. Symptoms include headache, nausea and vomiting, severe eye and nose irritation, excess salivation, and coughing. See also p 213.	0.05 ppm (C), S	2 mg/m ³		White solid crystals. Pepper-like odor. Vapor pressure is much less than 1 mm Hg at 20°C (68°F). CS is a common crowd control agent.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Chlorobromomethane (bromochloromethane, Halon 1011 [CAS: 74-97-5]): Irritating upon direct contact. Vapors mildly irritating to eyes and respiratory tract. A CNS depressant. Disorientation, nausea, headache, seizures, and coma have been reported at high exposure. Chronic high doses caused liver and kidney injury in test animals.	200 ppm	2000 ppm		Colorless to pale yellow liquid. Sweet, pleasant odor detectable far below the TLV. Vapor pressure is 117 mm Hg at 20°C (68°F). Thermal-breakdown products include hydrogen chloride, hydrogen bromide, and phosgene.
Chlorodifluoromethane (Freon 22 [CAS: 75-45-6]): Irritating upon direct contact. Vapors mildly irritating to eyes and respiratory tract. A CNS depressant. High-level exposure may cause arrhythmias. There is evidence at high doses for adverse effects on fetal development in test animals. See also p 209.	1000 ppm			Colorless, almost odorless gas. Nonflammable. Thermal-breakdown products may include hydrogen fluoride.
Chloroform (trichloromethane [CAS: 67-66-3]): Mildly irritating upon direct contact; dermatitis may result from prolonged exposure. Vapors slightly irritating to eyes and respiratory tract. A CNS depressant. High levels (15,000–20,000 ppm) can cause coma and cardiac arrhythmias. Can produce liver and kidney damage. Limited evidence of adverse effects on fetal development in test animals. A carcinogen in test animals (IARC 2B). See also p 154.	10 ppm, A3 NIOSH CA	500 ppm ERPG-2: 50 ppm ERPG-3: 5000 ppm	2 0 0	Colorless liquid. Pleasant, sweet odor. Not combustible. Vapor pressure is 160 mm Hg at 20°C (68°F). Breakdown products include hydrogen chloride, phosgene, and chlorine gas.
bis(Chloromethyl) ether (BCME [CAS: 542-88-1]): A human and animal carcinogen (IARC 1).	0.001 ppm, A1 OSHA CA NIOSH CA	ERPG-2: 0.1 ppm ERPG-3: 0.5 ppm		Colorless liquid with a suffocating odor. Vapor pressure is 100 mm Hg at 20°C (68°F). Used in the manufacture of ion-exchange resins.
Chloromethyl methyl ether (CMME, methyl chloromethyl ether [CAS: 107-30-2]): Vapors irritating to eyes and respiratory tract. Workers show increased risk of lung cancer, possibly owing to contamination of CMME with 1–7% BCME. (See above.)	A2 OSHA CA NIOSH CA	ERPG-2: 1 ppm ERPG-3: 10 ppm		Combustible. Breakdown products include oxides of nitrogen and hydrogen chloride. Used in the manufacture of ion-exchange resins.
1-Chloro-1-nitropropane (CAS: 600-25-9): Based on animal studies, vapors highly irritating to eyes and respiratory tract and may cause pulmonary edema. High levels may cause injury to cardiac muscle, liver, and kidney.	2 ppm	100 ppm	– 2 3	Colorless liquid. Unpleasant odor and tearing occur near the TLV and are good warning properties. Vapor pressure is 5.8 mm Hg at 20°C (68°F).

Chloropentafluoroethane (fluorocarbon 115 [CAS: 76-15-3]): Irritating upon direct contact. Vapors mildly irritating to eyes and respiratory tract. Produces coma and cardiac arrhythmias, but only at very high levels in test animals. See also p 209.	1000 ppm				Colorless, odorless gas. Thermal-breakdown products include hydrogen fluoride and hydrogen chloride.	
Chloropicrin (trichloronitromethane [CAS: 76-06-2]): Extremely irritating upon direct contact; severe burns may result. Vapors extremely irritating to eyes, skin, and respiratory tract; delayed pulmonary edema has been reported. Kidney and liver injuries have been observed in test animals.	0.1 ppm	2 ppm ERPG-1: 0.1 ppm ERPG-2: 0.3 ppm ERPG-3: 1.5 ppm	4	0	3	Colorless, oily liquid. Sharp, penetrating odor and tearing occur near the TLV and are good warning properties. Vapor pressure is 20 mm Hg at 20°C (68°F). Breakdown products include oxides of nitrogen, phosgene, nitrosyl chloride, and chlorine gas. Used as a fumigant and also as an additive for its warning properties.
β-Chloroprene (2-chloro-1,3-butadiene [CAS: 126-99-8]): Irritating upon direct contact. Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels. Liver and kidneys are major target organs. Limited evidence for adverse effects on fetal development and male reproduction in test animals. Equivocal evidence of carcinogenicity in test animals (IARC 3).	10 ppm, S NIOSH CA	300 ppm	2	3	0	Colorless liquid with an ether-like odor. Vapor pressure is 179 mm Hg at 20°C (68°F). Highly flammable. Breakdown products include hydrogen chloride. Used in making neoprene.
o-Chlorotoluene (2-chloro-1-methylbenzene [CAS: 95-49-8]): In test animals, direct contact produced skin and eye irritation; high vapor exposures resulted in tremors, convulsions, and coma. By analogy to toluene and chlorinated compounds, may cause cardiac arrhythmias.	50 ppm		2	2	0	Colorless liquid. Vapor pressure is 10 mm Hg at 43°C (109°F). Flammable.
Chlorpyrifos (Dursban, 0,0-diethyl-0-(3,5,6-trichloro-2-pyridinyl [CAS: 2921-88-2]): An organophosphate-type cholinesterase inhibitor (see p 291).	0.2 mg/m³, S					White solid crystals. Vapor pressure is 0.00002 mm Hg at 25°C (77°F).

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Chromic acid and chromates (chromium trioxide, sodium dichromate, potassium chromate): Highly irritating upon direct contact; severe eye and skin ulceration (chrome ulcers) may result. Dusts and mists highly irritating to eyes and respiratory tract. Skin and respiratory sensitization (asthma) may occur. Chromium trioxide is a teratogen in test animals. Certain hexavalent chromium compounds are carcinogenic in test animals and humans (IARC 1). See also p 167.	0.5 mg/m ³ (Cr III compounds) 0.05 mg/m ³ , A1 (water-soluble Cr VI compounds) 0.01 mg/m ³ , A1 (insoluble Cr IV compounds)	15 mg/m ³ (Cr VI)		Soluble chromate compounds are water-reactive. Chromates are common components of cement in concrete fabrication.
Chromium metal and insoluble chromium salts: Irritating upon direct contact with skin and eyes; dermatitis may result. Ferrochrome alloys possibly associated with pneumoconiotic changes. See also p 167.	0.5 mg/m ³ (metal, as Cr) 0.01 mg/m ³ , A1 (Cr VI compounds, as Cr)	250 mg/m ³ (Cr II compounds) 25 mg/m ³ (Cr III compounds) 250 mg/m ³ (Cr metal)		Chromium metal, silver luster; copper chromite, greenish-blue solid. Odorless.
Chromyl chloride (CAS: 14977-61-8): Hydrolyzes upon contact with moisture to produce chromic trioxide, HCl, chromic trichloride, and chlorine. Highly irritating upon direct contact; severe burns may result. Mists and vapors highly irritating to eyes and respiratory tract. Certain hexavalent chromium VI compounds are carcinogenic in test animals and humans. See also p 167.	0.025 ppm NIOSH CA			Dark red fuming liquid. Water-reactive, yielding hydrogen chloride, chlorine gas, chromic acid, and chromic chloride.
Coal tar pitch volatiles (particulate polycyclic aromatic hydrocarbons [CAS: 65996-93-2]): Irritating upon direct contact. Contact dermatitis, acne, hypermelanosis, and photosensitization may occur. Fumes irritating to eyes and respiratory tract. A carcinogen in test animals and humans.	0.2 mg/m ³ , A1 NIOSH CA	80 mg/m ³		A complex mixture composed of a high percentage of polycyclic aromatic hydrocarbons. A smoky odor. Combustible. Creosote is an important source of exposure.

Cobalt and compounds: Irritating upon direct contact; dermatitis and skin sensitization may occur. Fumes and dusts irritate the respiratory tract; chronic interstitial pneumonitis and respiratory tract sensitization reported. Cardiotoxicity associated with ingestion, but has not been well documented with occupational exposures. Evidence of carcinogenicity in test animals (IARC 2B).

0.02 mg/m³
(elemental and
inorganic
compounds, as
Co), A3

20 mg/m³
(as Co)

Elemental cobalt is a black or gray, odorless solid with a negligible vapor pressure. "Hard metal" used in specialty grinding and cutting is a tungsten carbide-cobalt amalgam.

Cobalt hydrocarbonyl (CAS: 16842-03-8): In animal testing, overexposure produces symptoms similar to those of nickel carbonyl and iron pentacarbonyl. Effects include headache, nausea, vomiting, dizziness, fever, and pulmonary edema.

0.1 mg/m³
(as Co)

Flammable gas.

Copper fumes, dusts, and salts: Irritation upon direct contact varies with the compound. The salts are more irritating and can cause corneal ulceration. Allergic contact dermatitis is rare. Dusts and mists irritating to the respiratory tract; nasal ulceration has been described. Ingestion can cause severe gastroenteritis and hepatic injury. See also p 175.

0.2 mg/m³ (fume)
1 mg/m³ (dust and mists)

100 mg/m³
(as Cu)

Salts vary in color. Generally odorless.

Cotton dust: Chronic exposure causes a respiratory syndrome called byssinosis. Symptoms include cough and wheezing, typically appearing on the first day of the workweek and continuing for a few days or all week, although they may subside within an hour after leaving work. Can lead to irreversible obstructive airway disease. A flu-like illness similar to metal fume fever (see p 259) also occurs among cotton workers ("Monday morning fever").

0.2 mg/m³

100 mg/m³

Cotton textile manufacture is the principal source of exposure.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Creosote (coal tar creosote [CAS: 8001-58-9]): A primary irritant, photosensitizer, and corrosive. Direct eye contact can cause severe keratitis and corneal scarring. Prolonged skin contact can cause chemical acne, pigmentation changes, and severe penetrating burns. Exposure to the fumes or vapors causes irritation of mucous membranes and the respiratory tract. Systemic toxicity results from phenolic and cresolic constituents. Liver and kidney injury may occur with heavy exposure. A carcinogen in test animals. Some evidence for carcinogenicity in humans (IARC 2A). See also phenol, p 302.	NIOSH CA		2 2 0	Oily, dark liquid. Appearance and some hazardous properties vary with the formulation. Sharp, penetrating smoky odor. Combustible. Creosote is produced by the fractional distillation of coal tar. See entry on coal tar pitch volatiles.
Cresol (methylphenol, cresylic acid, hydroxymethylbenzene [CAS: 1319-77-3]): Corrosive. Skin and eye contact can cause severe burns. Exposure may be prolonged owing to local anesthetic action on skin. Well absorbed by all routes. Dermal absorption is a major route of systemic poisoning. Induces methemoglobinemia (see p 261). CNS depressant. Symptoms include headache, nausea and vomiting, tinnitus, dizziness, weakness, and confusion. Severe lung, liver, and kidney injury may occur. See also phenol, p 302.	5 ppm, S	250 ppm	3 2 0 (ortho) 3 2 0 (meta, para)	Colorless, yellow, or pink liquid with a phenolic odor. Vapor pressure is 0.2 mm Hg at 20°C (68°F). Combustible.
Crotonaldehyde (2-butenal [CAS: 4170-30-3]): Highly irritating upon direct contact; severe burns may result. Vapors highly irritating to eyes and respiratory tract; delayed pulmonary edema may occur. Evidence for carcinogenicity in test animals.	0.3 ppm (C) S, A3	50 ppm ERPG-1: 2 ppm ERPG-2: 10 ppm ERPG-3: 50 ppm	4 3 2	Colorless to straw-colored liquid. Pungent, irritating odor occurs below the TLV and is an adequate warning property. A warning agent added to fuel gases. Vapor pressure is 30 mm Hg at 20°C (68°F). Flammable. Polymerizes when heated.
Crufomate (4-tert-butyl-2-chlorophenyl N-methyl O-methylphosphoramidate [CAS: 299-86-5]): An organophosphate cholinesterase inhibitor (see p 291).	5 mg/m ³			Crystals or yellow oil. Pungent odor. Flammable.

Cumene (isopropylbenzene [CAS: 98-82-8]): Mildly irritating upon direct contact. A CNS depressant at moderate levels. Well absorbed through skin. Adverse effects in fetal development in rats at high doses.	50 ppm	900 ppm [LEL]	2 3 1	Colorless liquid. Sharp, aromatic odor below the TLV is a good warning property. Vapor pressure is 8 mm Hg at 20°C (68°F). Flammable.
Cyanamide (carbodiimide [CAS: 420-04-2]): Causes transient vasomotor flushing. Highly irritating and caustic to eyes and skin. Has a disulfiram-like interaction with alcohol, producing flushing, headache, and dyspnea (see p 186).	2 mg/m ³		4 1 3	Combustible. Thermal-breakdown products include oxides of nitrogen.
Cyanide salts (sodium cyanide, potassium cyanide): Potent and rapidly fatal metabolic asphyxiants that inhibit cytochrome oxidase and stop cellular respiration. Well absorbed through skin; caustic action can promote dermal absorption. See also p 177.	5 mg/m ³ (C) (as cyanide), S	25 mg/m ³ (as cyanide)		Solids. Mild, almond-like odor. In presence of moisture or acids, hydrogen cyanide may be released. Odor is a poor indicator of exposure to hydrogen cyanide. May be generated in fires from the pyrolysis of such products as polyurethane and polyacrylonitrile.
Cyanogen (dicyan, oxalonitrile [CAS: 460-19-5]): Hydrolyzes to release hydrogen cyanide and cyanic acid. Toxicity similar to that of hydrogen cyanide (see p 177). Vapors irritating to eyes and respiratory tract.	10 ppm		4 4 2	Colorless gas. Pungent, almond-like odor. Breaks down on contact with water to yield hydrogen cyanide and cyanate. Flammable.
Cyanogen chloride (CAS: 506-77-4): Vapors extremely irritating to eyes and respiratory tract; pulmonary edema may result. Cyanide interferes with cellular respiration (see p 177).	0.3 ppm (C)	ERPG-2: 0.4 ppm ERPG-3: 4 ppm		Colorless liquid or gas with a pungent odor. Thermal-breakdown products include hydrogen cyanide and hydrogen chloride. Formed by a reaction with hypochlorite in the treatment of cyanide-containing wastewater.
Cyclohexane (CAS: 110-82-7): Mildly irritating upon direct contact. Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels. Chronically exposed test animals developed liver and kidney injury.	100 ppm	1300 ppm [LEL]	1 3 0	Colorless liquid with a sweet, chloroform-like odor. Vapor pressure is 95 mm Hg at 20°C (68°F). Highly flammable.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Cyclohexanol (CAS: 108-93-0): Irritating upon direct contact. Vapors irritating to eyes and respiratory tract. Well absorbed by skin. A CNS depressant at high levels. Based on animal tests, it may injure the liver and kidneys at high doses.	50 ppm, S	400 ppm	1 2 0	Colorless viscous liquid. Mild camphor-like odor. Irritation occurs near the TLV and is a good warning property. Vapor pressure is 1 mm Hg at 20°C (68°F). Combustible.
Cyclohexanone (CAS: 108-94-1): Irritating upon direct contact. Vapors irritate the eyes and respiratory tract. A CNS depressant at very high levels. Chronic, moderate doses caused slight liver injury in test animals.	25 ppm, S	700 ppm	1 2 0	Clear to pale yellow liquid with peppermint-like odor. Vapor pressure is 2 mm Hg at 20°C (68°F). Flammable.
Cyclohexene (1,2,3,4-tetrahydrobenzene (CAS: 110-83-8): By structural analogy to cyclohexane, may cause respiratory tract irritation. A CNS depressant.	300 ppm	2000 ppm	1 3 0	Colorless liquid with a sweet odor. Vapor pressure is 67 mm Hg at 20°C (68°F). Flammable. Readily forms peroxides and polymerizes.
Cyclohexylamine (aminocyclohexane (CAS: 108-91-8): Corrosive and highly irritating upon direct contact. Vapors highly irritating to eyes and respiratory tract. Pharmacologically active, possessing sympathomimetic activity. Weak methemoglobin-forming activity (see p 261). Very limited evidence for adverse effects on reproduction in test animals. Animal studies suggest brain, liver, and kidneys are target organs.	10 ppm		3 3 0	Liquid with an obnoxious, fishy odor. Flammable.
Cyclonite (RDX, trinitrotrimethylenetriamine (CAS: 121-82-4): Dermal and inhalation exposures affect the CNS with symptoms of confusion, headache, nausea, vomiting, convulsions, and coma. Does not have nitrate-like toxicity.	0.5 mg/m ³ , S			Crystalline solid. Vapor pressure is negligible at 20°C (68°F). Thermal-breakdown products include oxides of nitrogen. Explosive.
Cyclopentadiene (CAS: 542-92-7): Mildly irritating upon direct contact. Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels. Animal studies suggest some potential for kidney and liver injury at high doses.	75 ppm	750 ppm		Colorless liquid. Sweet, turpentine-like odor. Irritation occurs near the TLV and is a good warning property. Vapor pressure is high at 20°C (68°F). Flammable.

Cyclopentane (CAS: 287-92-31): Mildly irritating upon direct contact. Vapors irritating to eyes and respiratory tract. A CNS depressant at very high levels. Solvent mixtures containing cyclopentane have caused peripheral neuropathy although this may have been related to <i>n</i> -hexane in combination.	600 ppm		1 3 0	Colorless liquid with a faint hydrocarbon odor. Vapor pressure is about 400 mm Hg at 31°C (88°F). Flammable.
DDT (dichlorodiphenyltrichloroethane [CAS: 50-29-33]): Dusts irritating to eyes. Ingestion may cause tremor and convulsions. Chronic low-level exposure results in bioaccumulation. A carcinogen in test animals (IARC 2B). See also p 161.	1 mg/m ³ , A3 NIOSH CA	500 mg/m ³		Colorless, white, or yellow solid crystals with a faint aromatic odor. Vapor pressure is 0.0000002 mm Hg at 20°C (68°F). Combustible. Banned for use in US in 1973.
Decaborane (CAS: 17702-41-9): A potent CNS toxin. Symptoms include headache, dizziness, nausea, loss of coordination, and fatigue. Symptoms may be delayed in onset for 1–2 days; convulsions occur in more severe poisonings. Systemic poisonings can result from dermal absorption. Animal studies suggest a potential for liver and kidney injury.	0.05 ppm, S	15 mg/m ³	3 2 1	Colorless solid crystals with a pungent odor. Vapor pressure is 0.05 mm Hg at 25°C (77°F). Combustible. Reacts with water to produce flammable hydrogen gas. Used as a rocket fuel additive and as a rubber vulcanization agent.
Demeton (Systox, mercaptophos [CAS: 8065-48-31]): An organophosphate-type cholinesterase inhibitor (see p 291).	0.05 mg/m ³ , S	10 mg/m ³		A sulfur-like odor. A very low vapor pressure at 20°C (68°F). Thermal-breakdown products include oxides of sulfur.
Diacetone alcohol (4-hydroxy-4-methyl-2 pentanone [CAS: 123-42-21]): Irritating upon direct contact. Vapors very irritating to eyes and respiratory tract. A CNS depressant at high levels. Possibly some hemolytic activity.	50 ppm	1800 ppm [LEL]	1 2 0	Colorless liquid with an agreeable odor. Vapor pressure is 0.8 mm Hg at 20°C (68°F). Flammable.
Diazinon (0, O-diethyl O-2-isopropyl-4-methyl-6-pyrimidinylthio-phosphate [CAS: 333-41-51]): An organophosphate-type cholinesterase inhibitor (see p 291). Well absorbed dermally. Limited evidence for adverse effects on male reproduction and fetal development in test animals at high doses.	0.1 mg/m ³ , S			Commercial grades are yellow to brown liquids with a faint odor. Vapor pressure is 0.00014 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of nitrogen and sulfur.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Diazomethane (azimethylene, diazirine [CAS: 334-88-3]): Extremely irritating to eyes and respiratory tract; pulmonary edema has been reported. Immediate symptoms include cough, chest pain, and respiratory distress. A potent methylating agent and respiratory sensitizer.	0.2 ppm, A2	2 ppm		Yellow gas with a musty odor. Air mixtures and compressed liquids can be explosive when heated or shocked.
Diborane (boron hydride [CAS: 19287-45-7]): Extremely irritating to the respiratory tract; pulmonary edema may result. Repeated exposures have been associated with headache, fatigue, and dizziness; muscle weakness or tremors; and chills or fever. Animal studies suggest the liver and kidney are also target organs.	0.1 ppm	15 ppm ERPG-2: 1 ppm ERPG-3: 3 ppm	4 4 3 W	Colorless gas. Obnoxious, nauseatingly sweet odor. Highly flammable. Water-reactive; ignites spontaneously with moist air at room temperatures. A strong reducing agent. Breakdown products include boron oxide fumes. Used in microelectronic industry. Reacts violently with halogenated extinguishing agents.
1,2-Dibromo-3-chloropropane (DBCP [CAS: 96-12-8]): Irritant of eyes and respiratory tract. Has caused sterility (aspermia, oligospermia) in overexposed men. Well absorbed by skin contact and inhalation. A carcinogen in test animals (IARC 2B).	OSHA CA NIOSH CA			Brown liquid with a pungent odor. Combustible. Thermal-breakdown products include hydrogen bromide and hydrogen chloride. No longer used as a pesticide in the US.
1, 2-Dibromo-2,2-dichloroethyl dimethyl phosphate (Naled, Dibrom [CAS: 300-76-5]): An organophosphate anticholinesterase agent (see p 291). Highly irritating upon contact; eye injury is likely. Dermal sensitization can occur. Well absorbed dermally; localized muscular twitching results within minutes of contact.	0.1 mg/m ³ , S, SEN			Has a pungent odor. Vapor pressure is 0.002 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen bromide, hydrogen chloride, and phosphoric acid.
Dibutyl phosphate (di-<i>n</i>-butyl phosphate [CAS: 107-66-4]): A moderately strong acid likely to be irritating upon direct contact. Vapors and mists are irritating to the respiratory tract and have been associated with headache at low levels.	1 ppm	30 ppm		Colorless to brown liquid. Odorless. Vapor pressure is much less than 1 mm Hg at 20°C (68°F). Decomposes at 100°C (212°F) to produce phosphoric acid fumes.

Dibutyl phthalate (CAS: 84-74-2): Mildly irritating upon direct contact. Ingestion has produced nausea, dizziness, photophobia, and lacrimation but no permanent effects. Adverse effects on fetal development and male reproduction in test animals at very high doses.	5 mg/m ³	4000 mg/m ³	0 1 0	Colorless, oily liquid with a faint aromatic odor. Vapor pressure is less than 0.01 mm Hg at 20°C (68°F). Combustible.
1, 2-Dichloroacetylene (CAS: 7572-29-4): Vapors extremely irritating to eyes and respiratory tract; pulmonary edema may result. CNS toxicity includes nausea and vomiting, headache, involvement of trigeminal nerve and facial muscles, and outbreaks of facial herpes. Limited evidence for carcinogenicity in test animals.	0.1 ppm (C), A3			Colorless liquid.
<i>o</i>-Dichlorobenzene (1,2-dichlorobenzene [CAS: 95-50-1]): Irritating upon direct contact; skin blisters and hyperpigmentation may result from prolonged contact. Vapor also irritating to eyes and respiratory tract. Highly hepatotoxic in test animals. Evidence for adverse effects on male reproduction in test animals.	25 ppm	200 ppm	2 2 0	Colorless to pale yellow liquid. Aromatic odor and eye irritation occur well below the TLV and are adequate warning properties. Thermal-breakdown products include hydrogen chloride and chlorine gas.
<i>p</i>-Dichlorobenzene (1,4-dichlorobenzene [CAS: 106-46-7]): Irritating upon direct contact with the solid. Vapors irritating to eyes and respiratory tract. Systemic effects include headache, nausea, vomiting, and liver injury. The <i>ortho</i> isomer is more toxic to the liver. A carcinogen in test animals (IARC 2B).	10 ppm, A3	150 ppm	2 2 0	Colorless or white solid. Mothball odor and irritation occur near the TLV and are adequate warning properties. Vapor pressure is 0.4 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include hydrogen chloride. Used as a moth repellent.
3,3'-Dichlorobenzidine (CAS: 91-94-1): Well absorbed by the dermal route. Animal studies suggest that severe eye injury and respiratory tract irritation may occur. A potent carcinogen in test animals (IARC 2B).	S, A3 OSHA CA NIOSH CA			Crystalline needles with a faint odor.
Dichlorodifluoromethane (Freon 12, Fluorocarbon 12 [CAS: 75-71-8]): Mild eye and respiratory tract irritant. Extremely high exposures (eg, 100,000 ppm) can cause coma and cardiac arrhythmias. See also p 209.	1000 ppm	15,000 ppm		Colorless gas. Ether-like odor is a poor warning property. Vapor pressure is 5.7 mm Hg at 20°C (68°F). Not combustible. Decomposes slowly on contact with water or heat to produce hydrogen chloride, hydrogen fluoride, and phosgene.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <— 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
1,3-Dichloro-5,5-dimethylhydantoin (Halane, Dactin [CAS: 118-52-5]): Releases hypochlorous acid and chlorine gas (see p 162) on contact with moisture. Direct contact with the dust or concentrated solutions irritating to eyes, skin, and respiratory tract.	0.2 mg/m ³	5 mg/m ³		White solid with a chlorine-like odor. Odor and eye irritation occur below the TLV and are adequate warning properties. Not combustible. Thermal-breakdown products include hydrogen chloride, phosgene, oxides of nitrogen, and chlorine gas.
1,1-Dichloroethane (ethylidene chloride [CAS: 75-34-3]): Mild eye and skin irritant. Vapors irritating to the respiratory tract. A CNS depressant at high levels. By analogy with its 1,2-isomer, may cause arrhythmias. Animal studies suggest some potential for kidney and liver injury.	100 ppm	3000 ppm	2 3 0	Colorless, oily liquid. Chloroform-like odor occurs at the TLV. Vapor pressure is 182 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include vinyl chloride, hydrogen chloride, and phosgene.
1,2-Dichloroethane (ethylene dichloride [CAS: 107-06-2]): Irritating upon prolonged contact; burns may occur. Well absorbed dermally. Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels. May cause cardiac arrhythmias. Severe liver and kidney injury has been reported. A carcinogen in test animals (IARC 2B).	10 ppm NIOSH CA	50 ppm ERPG-1: 50 ppm ERPG-2: 200 ppm ERPG-3: 200 ppm	2 3 0	Flammable. Thermal-breakdown products include hydrogen chloride and phosgene.
1,1-Dichloroethylene (vinylidene chloride [CAS: 75-35-4]): Irritating upon direct contact. Vapors very irritating to eyes and respiratory tract. A CNS depressant. May cause cardiac arrhythmias. In test animals, damages the liver and kidneys. Limited evidence of carcinogenicity in test animals (IARC 3).	5 ppm, A4 NIOSH CA		4 4 2	Colorless liquid. Sweet, ether-like or chloroform-like odor occurs below the TLV and is a good warning property. Polymerizes readily.
1,2-Dichloroethylene (1,2-dichloroethene, acetylene dichloride [CAS: 540-59-0]): Vapors mildly irritating to respiratory tract. A CNS depressant at high levels; once used as an anesthetic agent. May cause cardiac arrhythmias. Low hepatotoxicity.	200 ppm	1000 ppm	2 3 2	Colorless liquid with a slightly acrid, ether-like or chloroform-like odor. Vapor pressure is about 220 mm Hg at 20°C (68°F). Thermal-breakdown products include hydrogen chloride and phosgene.

Dichloroethyl ether (bis[2-chloroethyl] ether, dichloroethyl oxide [CAS: 111-44-4]): Irritating upon direct contact; corneal injury may result. Vapors highly irritating to respiratory tract. A CNS depressant at high levels. Dermal absorption occurs. Animal studies suggest the liver and kidneys are also target organs at high exposures. Limited evidence for carcinogenicity in test animals.	5 ppm, S	100 ppm	3 2 1	Colorless liquid. Obnoxious, chlorinated solvent odor occurs at the TLV and is a good warning property. Flammable. Breaks down on contact with water. Thermal-breakdown products include hydrogen chloride.
Dichlorofluoromethane (fluorocarbon 21, Freon 21, Halon 112 [CAS: 75-43-4]): Animal studies suggest much greater hepatotoxicity than most common chlorofluorocarbons. Causes CNS depression, respiratory irritation, and cardiac arrhythmias at very high air levels (eg, 100,000 ppm). Evidence for adverse effects on fetal development (preimplantation losses) in test animals at high levels. See also p 209.	10 ppm	5000 ppm		Colorless liquid or gas with a faint ether-like odor. Thermal-breakdown products include hydrogen chloride, hydrogen fluoride, and phosgene.
1,1-Dichloro-1-nitroethane [CAS: 594-72-9]): Based on animal studies, highly irritating upon direct contact. Vapors highly irritating to eyes, skin, and respiratory tract; pulmonary edema may result. In test animals, lethal doses also injured the liver, heart, and kidneys.	2 ppm	25 ppm	2 2 3	Colorless liquid. Obnoxious odor and tearing occur only at dangerous levels and are poor warning properties. Vapor pressure is 15 mm Hg at 20°C (68°F).
2,4-Dichlorophenoxyacetic acid (2,4-D [CAS: 94-75-9]): Direct skin contact can produce a rash. Overexposed workers have rarely experienced peripheral neuropathy. Severe rhabdomyolysis and minor liver and kidney injury may occur. Adverse effects on fetal development at high doses in test animals. There are weak epidemiologic associations of phenoxy herbicides with soft-tissue sarcomas. See also p 184.	10 mg/m ³	100 mg/m ³		White to yellow crystals. Appearance and some hazardous properties vary with the formulation. Odorless. Vapor pressure is negligible at 20°C (68°F). Thermal-breakdown products include hydrogen chloride and phosgene.
1,3-Dichloropropene (1,3-dichloropropylene, Telone [CAS: 542-75-6]): Based on animal studies, irritating upon direct contact. Well absorbed dermally. Vapors irritating to eyes and respiratory tract. In test animals, moderate doses caused severe injuries to the liver, pancreas, and kidneys. A carcinogen in test animals (IARC 2B).	1 ppm, S		2 3 0	Colorless or straw-colored liquid. Sharp, chloroform-like odor. Polymerizes readily. Vapor pressure is 28 mm Hg at 25°C (77°F). Thermal-breakdown products include hydrogen chloride and phosgene.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
2,2-Dichloropropionic acid (CAS: 75-99-0): Corrosive upon direct contact with concentrate; severe burns may result. Vapors mildly irritating to eyes and respiratory tract.	5 mg/m ³			Colorless liquid. The sodium salt is a solid.
Dichlorotetrafluoroethane (fluorocarbon 114, Freon 114 [CAS: 76-14-2]): Vapors may sensitize the myocardium to arrhythmogenic effects of epinephrine at modestly high air levels (25,000 ppm). Other effects at higher levels (100,000–200,000 ppm) include respiratory irritation and CNS depression. See also p 209.	1000 ppm	15,000 ppm		Colorless gas with a mild ether-like odor. Thermal breakdown products include hydrogen chloride, hydrogen fluoride, and phosgene.
Dichlorvos (DDVP, 2,2-dichlorovinyl dimethyl phosphate [CAS: 62-73-7]): An organophosphate-type cholinesterase inhibitor (see p 291). Extremely well absorbed through skin. Evidence of carcinogenicity in test animals (IARC 2B).	0.1 mg/m ³ , S, SEN	100 mg/m ³		Colorless to amber liquid with a slight chemical odor. Vapor pressure is 0.032 mm Hg at 32°C (90°F).
Dicrotophos (dimethyl <i>cis</i>-2-dimethylcarbamoyl-1-methylvinyl phosphate, Bidrin [CAS: 141-66-2]): An organophosphate cholinesterase inhibitor (see p 291). Dermal absorption occurs.	0.05 mg/m ³ , S			Brown liquid with a mild ester odor.
Dieldrin (CAS: 60-57-1): Minor skin irritant. Potent convulsant and hepatotoxin. Dermal absorption is a major route of systemic poisoning. Overexposures produce headache, dizziness, twitching, and convulsions. Limited evidence for adverse effects on fetal development and carcinogenicity in test animals (IARC 3). See also p 161.	0.25 mg/m ³ , S NIOSH CA	50 mg/m ³		Light brown solid flakes with a mild chemical odor. Appearance and some hazardous properties vary with the formulation. Vapor pressure is 0.0000002 mm Hg at 32°C (90°F). Not combustible.
Diesel exhaust: A respiratory irritant. May act as an adjuvant to immunologic sensitization. Animal and epidemiological studies provide evidence of pulmonary carcinogenicity. (IARC 2A) See also carbon monoxide, p 151.	0.02 mg/m ³ , A2 (particulate) NIOSH CA 100 mg/m ³ , S (liquid fuel)			Diesel engines emit a complex mixture of gases, vapors, and respirable particles, including many polycyclic aromatic and nitroaromatic hydrocarbons and oxides of nitrogen, sulfur, and carbon including carbon monoxide.

Diethylamine (CAS: 109-89-7): Corrosive. Highly irritating upon direct contact; severe burns may result. Vapors highly irritating to eyes and respiratory tract; pulmonary edema may occur. Subacute animal studies suggest liver and heart may be target organs.	5 ppm, S	200 ppm	3 3 0	Colorless liquid. Fishy, ammonia-like odor occurs below the TLV and is a good warning property. Vapor pressure is 195 mm Hg at 20°C (68°F). Highly flammable. Thermal-breakdown products include oxides of nitrogen.
2-Diethylaminoethanol (N,N-diethylthanolamine, DEAE [CAS: 100-37-8]): Based on animal studies, highly irritating upon direct contact and a skin sensitizer. Vapors likely irritating to eyes, skin, and respiratory tract. Reports of nausea and vomiting after a momentary exposure to 100 ppm.	2 ppm, S	100 ppm	3 2 0	Colorless liquid. Weak to nauseating ammonia odor. Flammable. Thermal-breakdown products include oxides of nitrogen.
Diethylenetriamine (DETA [CAS: 111-40-0]): Corrosive; highly irritating upon direct contact; severe burns may result. Vapors highly irritating to eyes and respiratory tract. Dermal and respiratory sensitization can occur.	1 ppm, S		3 1 0	Viscous yellow liquid with an ammonia-like odor. Vapor pressure is 0.37 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include oxides of nitrogen.
Diethyl ketone (3-pentanone [CAS: 96-22-0]): Mildly irritating upon direct contact. Vapors mildly irritating to eyes and respiratory tract.	200 ppm		1 3 0	Colorless liquid with an acetone-like odor. Flammable.
Diethyl sulfate (CAS: 64-67-5): Strong eye and respiratory tract irritant. Sufficient evidence of carcinogenicity in test animals. Limited evidence (laryngeal cancers) in humans (IARC 2A).			3 1 1	An alkylating agent. Colorless oily liquid with a peppermint odor.
Difluorodibromomethane (dibromodifluoromethane, Freon 12B2 [CAS: 75-61-6]): Based on animal tests, vapors irritate the respiratory tract. A CNS depressant. By analogy to other freons, may cause cardiac arrhythmias. In test animals, high-level chronic exposures caused lung, liver, and CNS injury. See also p 209.	100 ppm	2000 ppm		Heavy, volatile, colorless liquid with an obnoxious, distinctive odor. Vapor pressure is 620 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen bromide and hydrogen fluoride.
Diglycidyl ether (di[2,3-epoxypropyl]-ether, DGE [CAS: 2238-07-5]): Extremely irritating upon direct contact; severe burns result. Vapors highly irritating to eyes and respiratory tract; pulmonary edema may result. Testicular atrophy and adverse effects on the hematopoietic system at low doses in test animals. CNS depression also noted. An alkylating agent and a carcinogen in test animals.	0.1 ppm NIOSH CA	10 ppm		Colorless liquid with a very irritating odor. Vapor pressure is 0.09 mm Hg at 25°C (77°F).

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Diisobutyl ketone (2,6-dimethyl-4-heptanone [CAS: 108-83-8]): Mildly irritating upon direct contact. Vapors mildly irritate eyes and respiratory tract. A CNS depressant at high levels.	25 ppm	500 ppm	1 2 0	Colorless liquid with a weak, ether-like odor. Vapor pressure is 1.7 mm Hg at 20°C (68°F).
Diisopropylamine (CAS: 108-18-9): Corrosive. Highly irritating upon direct contact; severe burns may result. Vapors very irritating to eyes and respiratory tract. Workers exposed to levels of 25–50 ppm have complained of hazy vision, nausea, and headache.	5 ppm, S	200 ppm	3 3 0	Colorless liquid with an ammonia-like odor. Vapor pressure is 60 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include oxides of nitrogen.
Dimethyl acetamide (DMAC [CAS: 127-19-5]): Potent hepatotoxin. Inhalation and skin contact are major routes of absorption. Limited evidence for adverse effects on fetal development in test animals at high doses.	10 ppm, S	300 ppm	2 2 0	Colorless liquid with a weak ammonia-like odor. Vapor pressure is 1.5 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include oxides of nitrogen.
Dimethylamine (DMA [CAS: 124-40-3]): Corrosive upon direct contact; severe burns may result. Vapors extremely irritating to eyes and respiratory tract. Animal studies suggest liver is a target organ.	5 ppm	500 ppm ERPG-1: 1 ppm ERPG-2: 100 ppm ERPG-3: 500 ppm	3 4 0	Colorless liquid or gas. Fishy or ammonia-like odor far below TLV is a good warning property. Flammable. Thermal-breakdown products include oxides of nitrogen.
<i>N,N</i>-Dimethylaniline (CAS: 121-69-7): Causes methemoglobinemia (see p 261). A CNS depressant. Well absorbed dermally. Limited evidence for carcinogenicity in test animals.	5 ppm, S	100 ppm	3 2 0	Straw- to brown-colored liquid with an amine-like odor. Vapor pressure is less than 1 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include oxides of nitrogen.
Dimethylcarbamoyl chloride (CAS: 79-44-7): Rapidly hydrolyzed by moisture to dimethylamine, carbon dioxide, and hydrochloric acid. Expected to be extremely irritating upon direct contact or by inhalation. A carcinogen in test animals (IARC 2A).	A2			Liquid. Rapidly reacts with moisture to yield dimethylamine and hydrogen chloride.

<i>N,N</i>-Dimethylformamide (DMF [CAS: 68-12-2]): Dermally well absorbed. Symptoms of overexposure include abdominal pain, nausea, and vomiting. This chemical is a potent hepatotoxin in humans. Interferes with ethanol to cause disulfiram-like reactions (see p 186). Limited epidemiologic association with an increased risk of testicular cancer (IARC 2B). Limited evidence for adverse effects on fetal development in animals.	10 ppm, S	500 ppm ERPG-1: 2 ppm ERPG-2: 100 ppm ERPG-3: 200 ppm	1 2 0	Colorless to pale yellow liquid. Faint ammonia-like odor is a poor warning property. Vapor pressure is 2.7 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include oxides of nitrogen.
1,1-Dimethylhydrazine (DMH, UDMH [CAS: 57-14-7]): Corrosive upon direct contact; severe burns may result. Vapors extremely irritating to eyes and respiratory tract; pulmonary edema may occur. Well absorbed through the skin. May cause methemoglobinemia (see p 261); may cause hemolysis. A potent hepatotoxin, and a carcinogen in test animals (IARC 2B).	0.01 ppm, S, NIOSH CA	15 ppm	4 3 1	Colorless liquid with yellow fumes. Amine odor. Vapor pressure is 1.3 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of nitrogen.
Dimethylmercury (mercury dimethyl, [CAS 593-74-8]): Extremely toxic liquid readily absorbed by inhalation or across intact skin; as little as 1–2 drops on a latex glove caused death in a research chemist. Neurotoxic effects include progressive ataxia, dysarthria, visual and auditory dysfunction, and coma.	OSHA PEL for alkyl mercury compounds in general: 0.01 mg/m ³			Colorless liquid with a weak, sweet odor. Density 3.2 g/mL. Vapor pressure 50–82 mm Hg at 20°C (68°F). Permeable through latex, neoprene, and butyl rubber gloves. (OSHA recommends Silver Shield laminate gloves under outer gloves.)
Dimethyl sulfate (CAS: 77-78-1): Powerful vesicant action; hydrolyzes to sulfuric acid and methanol. Extremely irritating upon direct contact; severe burns have resulted. Vapors irritating to eyes and respiratory tract; delayed pulmonary edema may result. Skin absorption is rapid. A carcinogen in test animals (IARC 2A).	0.1 ppm, S, A3	7 ppm	4 2 0	Colorless, oily liquid. Very mild onion odor is barely perceptible and is a poor warning property. Vapor pressure is 0.5 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include sulfur oxides.
Dinitrobenzene: May stain tissues yellow upon direct contact. Vapors are irritating to respiratory tract. Potent inducer of methemoglobinemia (see p 261). Chronic exposures may result in anemia and liver damage. Injuries testes in test animals. Very well absorbed through the skin.	0.15 ppm, S	50 mg/m ³	3 1 4	Pale yellow crystals. Explosive; detonated by heat or shock. Vapor pressure is much less than 1 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of nitrogen.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Dinitro-o-cresol (2-methyl-4,6-dinitrophenol [CAS: 534-52-1]): Highly toxic; uncouples oxidative phosphorylation in mitochondria, increasing metabolic rate and leading to fatigue, sweating, rapid breathing, tachycardia, and fever. Liver and kidney injury may occur. Symptoms may last for days, as it is very slowly excreted. May induce methemoglobinemia (see p 261). Poisonings may result from dermal exposure. Yellow-stained skin may mark exposure.	0.2 mg/m ³ , S	5 mg/m ³		Yellow solid crystals. Odorless. Dust is explosive. Vapor pressure is 0.00005 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of nitrogen.
2,4-Dinitrophenol (CAS: 25550-58-7): Potent uncoupler of oxidative phosphorylation. Initial findings include hypertension, fever, dyspnea, and tachypnea. May cause methemoglobinemia and harm liver and kidneys. May stain skin at point of contact. Limited evidence for adverse effects on fetal development. See also p 298.				
2,4-Dinitrotoluene (DNT [CAS: 25321-14-6]): May cause methemoglobinemia (see p 261). Uncouples oxidative phosphorylation, leading to increased metabolic rate and hyperthermia, tachycardia, and fatigue. A hepatotoxin. May cause vasodilation; headache and drop in blood pressure are common. Cessation of exposure may precipitate angina pectoris in pharmacologically dependent workers. Well absorbed by all routes. May stain skin yellow. Injures testes in test animals and possibly, exposed workers. A carcinogen in test animals.	0.2 mg/m ³ , A3, S NIOSH CA	50 mg/m ³	3 1 3	Orange-yellow solid (pure) or oily liquid with a characteristic odor. Explosive. Thermal-breakdown products include oxides of nitrogen. Vapor pressure is 1 mm Hg at 20°C (68°F).
1,4-Dioxane (1,4-diethylene dioxide [CAS: 123-91-1]): Vapors irritating to eyes and respiratory tract. Inhalation or dermal exposures may cause gastrointestinal upset and liver and kidney injury. A carcinogen in test animals (IARC 2B).	20 ppm, S, A3 NIOSH CA	500 ppm	2 3 1	Colorless liquid. Mild ether-like odor occurs only at dangerous levels and is a poor warning property. Vapor pressure is 29 mm Hg at 20°C (68°F). Flammable.
Dioxathion (2,3-<i>p</i>-dioxanedithiol <i>S,S</i>-bis [<i>O,O</i>-diethyl phosphorodithioate] [CAS: 78-34-2]): An organophosphate-type cholinesterase inhibitor (see p 291). Well absorbed dermally.	0.1 mg/m ³ , S			Amber liquid. Vapor pressure is negligible at 20°C (68°F). Thermal-breakdown products include oxides of sulfur.

Dipropylene glycol methyl ether (DPGME [CAS: 34590-94-8]): Mildly irritating to eyes upon direct contact. A CNS depressant at very high levels.	100 ppm, S	600 ppm	0 2 0	Colorless liquid with a mild ether-like odor. Nasal irritation is a good warning property. Vapor pressure is 0.3 mm Hg at 20°C (68°F). Combustible.
Diquat (1,1-ethylene-2,2'-dipyridinium dibromide, Reglone, Dextro [CAS: 85-00-7]): Corrosive in high concentrations. Acute renal failure and reversible liver injury may occur. Chronic feeding studies caused cataracts in test animals. Although pulmonary edema might occur, unlike paraquat, pulmonary fibrosis has not been shown with human diquat exposures. See also p 296.	0.5 mg/m ³ (total dust) 0.1 mg/m ³ (respirable dust), S			Yellow solid crystals. Appearance and some hazardous properties vary with the formulation.
Disulfiram (tetraethylthiuram disulfide, Antabuse [CAS: 97-77-8]): Inhibits aldehyde dehydrogenase, an enzyme involved in ethanol metabolism. Exposure to disulfiram and alcohol will produce flushing, headache, and hypotension. Disulfiram may also interact with other industrial solvents that share metabolic pathways with ethanol. Limited evidence for adverse effects on fetal development in test animals. See also p 186.	2 mg/m ³			Crystalline solid. Thermal-breakdown products include oxides of sulfur.
Disulfoton (O,O-diethyl-S-ethylmercapto-ethyl dithiophosphate [CAS: 298-04-4]): An organophosphate-type cholinesterase inhibitor (see p 291). Dermally well absorbed.	0.05 mg/m ³ , S			Vapor pressure is 0.00018 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of sulfur.
Divinylbenzene (DVB, vinylstyrene [CAS: 1321-74-0]): Mildly irritating upon direct contact. Vapors mildly irritating to eyes and respiratory tract.	10 ppm		1 2 2	Pale yellow liquid. Combustible. Must contain inhibitor to prevent explosive polymerization.
Emery (corundum, impure aluminum oxide [CAS: 112-62-9]): An abrasive, nuisance dust causing physical irritation to eyes, skin, and respiratory tract.	10 mg/m ³			Solid crystals of aluminum oxide. Often used for its abrasive properties (eg, emery cloth, emery wheel).

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Endosulfan (CAS: 115-29-7): Inhalation and skin absorption are major routes of exposure. Symptoms include nausea, confusion, excitement, twitching, and convulsions. Animal studies suggest liver and kidney injury from very high exposures. Limited evidence for adverse effects on male reproduction and fetal development in animal studies. See also p 161.	0.1 mg/m ³ , S			Chlorinated hydrocarbon insecticide. Tan, waxy solid with a mild sulfur dioxide odor. Thermal-breakdown products include oxides of sulfur and hydrogen chloride.
Endrin (CAS: 72-20-8): Endrin is the stereoisomer of dieldrin, and its toxicity is very similar. Well absorbed through skin. Overexposure may produce headache, dizziness, nausea, confusion, twitching, and convulsions. Adverse effects on fetal development in test animals. See also p 161.	0.1 mg/m ³ , S	2 mg/m ³		Colorless, white, or tan solid. A stereoisomer of dieldrin. A mild chemical odor and negligible vapor pressure of 0.0000002 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen chloride.
Environmental tobacco smoke: Passive smoking causes respiratory irritation and small reductions in lung function. It increases severity and frequency of asthmatic attacks in children. May cause coughing, phlegm production, chest discomfort, and reduced lung function in adults. Causes developmental toxicity in infants and children and reproductive toxicity in adult females. Epidemiological studies show passive smoking causes lung cancer (IARC 1).				
Epichlorohydrin (chloropropylene oxide [CAS: 106-89-8]): Extremely irritating upon direct contact; severe burns may result. Vapors highly irritating to eyes and respiratory tract; pulmonary edema has been reported. Other effects include nausea, vomiting, and abdominal pain. Sensitization has been occasionally reported. Animal studies suggest a potential for liver and kidney injury. High doses reduce fertility in test animals. A carcinogen in test animals (IARC 2A).	0.5 ppm, S, A3 NIOSH CA	75 ppm ERPG-1: 2 ppm ERPG-2: 20 ppm ERPG-3: 100 ppm	3 3 2	Colorless liquid. The irritating, chloroform-like odor is detectable only at extremely high exposures and is a poor warning property. Vapor pressure is 13 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include hydrogen chloride and and phosgene.
EPN (O-ethyl O-p-nitrophenyl phenylphosphonothioate [CAS: 2104-64-5]): An organophosphate-type cholinesterase inhibitor (see p 291).	0.1 mg/m ³ , S	5 mg/m ³		Yellow solid or brown liquid. Vapor pressure is 0.0003 mm Hg at 100°C (212°F).

Ethanolamine (2-aminoethanol [CAS: 141-43-5]): Highly irritating upon direct contact; severe burns may result. Prolonged contact with skin is irritating. Animal studies suggest that, at high levels, vapors are irritating to eyes and respiratory tract and liver and kidney injury may occur. Limited evidence for adverse effects on fetal development in animal studies.	3 ppm	30 ppm	3 2 0	Colorless liquid. A mild ammonia-like odor occurs at the TLV and is an adequate warning property. Vapor pressure is less than 1 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include oxides of nitrogen.
Ethion (phosphorodithioic acid [CAS: 563-12-2]): An organophosphate-type cholinesterase inhibitor (see p 291). Well absorbed dermally.	0.4 mg/m ³ , S			Colorless, odorless liquid when pure. Technical products have an objectionable odor. Vapor pressure is 0.000002 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of sulfur.
2-Ethoxyethanol (ethylene glycol monoethyl ether, EGEE, Cello-solve [CAS: 110-80-5]): Mildly irritating on direct contact. Skin contact is a major route of absorption. Overexposures may reduce sperm counts in men. A potent teratogen in both rats and rabbits. Large doses cause lung, liver, testes, kidney, and spleen injury in test animals. See also p 194.	5 ppm, S	500 ppm	2 2 0	Colorless liquid. Very mild, sweet odor occurs only at very high levels and is a poor warning property. Vapor pressure is 4 mm Hg at 20°C (68°F).
2-Ethoxyethyl acetate (ethylene glycol monoethyl ether acetate, Cellosolve acetate): Mildly irritating upon direct contact. May produce CNS depression and kidney injury. Skin contact is a major route of absorption. Metabolized to 2-ethoxyethanol. Adverse effects on fertility and fetal development in animals. See also p 194.	5 ppm, S	500 ppm	2 2 0	Colorless liquid. Mild ether-like odor occurs at the TLV and is a good warning property. Flammable.
Ethyl acetate (CAS: 141-78-6): Slightly irritating to eyes and skin. Vapors irritating to eyes and respiratory tract. A CNS depressant at very high levels. Metabolized to ethanol and acetic acid, so may have some of the fetotoxic potential of ethanol.	400 ppm	2000 ppm [LEL]	1 3 0	Colorless liquid. Fruity odor occurs at the TLV and is a good warning property. Vapor pressure is 76 mm Hg at 20°C (68°F). Flammable.
Ethyl acrylate (CAS: 140-88-5): Extremely irritating upon direct contact; severe burns may result. A skin sensitizer. Vapors highly irritating to eyes and respiratory tract. In animal tests, heart, liver, and kidney damage was observed at high doses. A carcinogen in test animals (IARC 2B).	5 ppm	300 ppm ERPG-1: 0.01 ppm ERPG-2: 30 ppm ERPG-3: 300 ppm	2 3 2	Colorless liquid. Acrid odor occurs below the TLV and is a good warning property. Vapor pressure is 29.5 mm Hg at 20°C (68°F). Flammable. Contains an inhibitor to prevent dangerous self-polymerization.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <— 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Ethyl alcohol (alcohol, grain alcohol, ethanol, EtOH [CAS: 64-17-5]): At high levels, vapors irritating to eyes and respiratory tract. A CNS depressant at high levels of exposure. Strong evidence for adverse effects on fetal development in test animals and humans with chronic ingestion (fetal alcohol syndrome). See also p 190.	1000 ppm	3300 ppm [LEL]	0 3 0	Colorless liquid with a mild, sweet odor. Vapor pressure is 43 mm Hg at 20°C (68°F). Flammable.
Ethylamine (CAS: 75-04-7): Corrosive upon direct contact; severe burns may result. Vapors highly irritating to eyes, skin, and respiratory tract; delayed pulmonary edema may result. Animal studies suggest potential for liver and kidney injury at moderate doses.	5 ppm, S	600 ppm	3 4 0	Colorless liquid or gas with an ammonia-like odor. Highly flammable. Thermal-breakdown products include oxides of nitrogen.
Ethyl amyl ketone (5-methyl-3-heptanone [CAS: 541-85-5]): Irritating to eyes upon direct contact. Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels.	25 ppm			Colorless liquid with a strong, distinctive odor. Flammable.
Ethylbenzene (CAS: 100-41-4): Mildly irritating to eyes upon direct contact. May cause skin burns upon prolonged contact. Dermally well absorbed. Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels of exposure.	100 ppm, A3	800 ppm [LEL]	2 3 0	Colorless liquid. Aromatic odor and irritation occur at levels close to the TLV and are adequate warning properties. Vapor pressure is 7.1 mm Hg at 20°C (68°F). Flammable.
Ethyl bromide (CAS: 74-96-4): Irritating to skin upon direct contact. Irritating to respiratory tract. A CNS depressant at high levels, and may cause cardiac arrhythmias. Former use as an anesthetic agent was discontinued because of fatal liver, kidney, and myocardial injury. Evidence for carcinogenicity in test animals.	5 ppm, S, A3	2000 ppm	2 1 0	Colorless to yellow liquid. Ether-like odor detectable only at high, dangerous levels. Vapor pressure is 375 mm Hg at 20°C (68°F). Highly flammable. Thermal-breakdown products include hydrogen bromide and bromine gas.
Ethyl butyl ketone (3-heptanone [CAS: 106-35-4]): Mildly irritating to eyes upon direct contact. Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels.	50 ppm	1000 ppm	1 2 0	Colorless liquid. Fruity odor is a good warning property. Vapor pressure is 4 mm Hg at 20°C (68°F). Flammable.

Ethyl chloride (CAS: 75-00-3): Mildly irritating to eyes and respiratory tract. A CNS depressant at high levels; has caused cardiac arrhythmias at anesthetic doses. Animal studies suggest the kidneys and liver are target organs at high doses. Structurally similar to the carcinogenic chloroethanes.	100 ppm, A3, S	3800 ppm [LEL]	1 4 0	Colorless liquid or gas with a pungent, ether-like odor. Highly flammable. Thermal-breakdown products include hydrogen chloride and phosgene.
Ethylene chlorohydrin (2-chloroethanol [CAS: 107-07-3]): Irritating to eyes upon direct contact. Skin contact is extremely hazardous because it is not irritating and absorption is rapid. Vapors irritating to eyes and respiratory tract; pulmonary edema has been reported. Systemic effects include CNS depression, myocardial pathology, shock, and liver and kidney damage.	1 ppm (C), S	7 ppm	4 2 0	Colorless liquid with a weak ether-like odor. Vapor pressure is 5 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include hydrogen chloride and phosgene.
Ethylenediamine (CAS: 107-15-3): Highly irritating upon direct contact; burns may result. Respiratory and dermal sensitization may occur. Vapors irritating to eyes and respiratory tract. Animal studies suggest potential for kidney injury at high doses.	10 ppm, S	1000 ppm	3 2 0	Colorless viscous liquid or solid. Ammonia-like odor occurs at the PEL and is an adequate warning property. Vapor pressure is 10 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include oxides of nitrogen.
Ethylene dibromide (1,2-dibromoethane, EDB [CAS: 106-93-4]): Highly irritating upon direct contact; severe burns result. Highly toxic by all routes. Vapors highly irritating to eyes and respiratory tract. Severe liver and kidney injury may occur. A CNS depressant. Adverse effects on the testes in test animals and, possibly, humans. A carcinogen in test animals (IARC 2A). See p 193.	S, A3 NIOSH CA	100 ppm	3 0 0	Colorless liquid or solid. Mild, sweet odor is a poor warning property. Vapor pressure is 11 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen bromide and bromine gas. Fumigant and chemical intermediate used in organic synthesis.
Ethylene glycol (antifreeze [CAS: 107-21-1]): A CNS depressant. Metabolized to oxalic and other acids; severe acidosis may result. Precipitation of calcium oxalate crystals in tissues can cause extensive injury. Adversely affects fetal development in animal studies at very high doses. Not well absorbed dermally. See also p 194.	100 mg/m ³ (C)		1 1 0	Colorless viscous liquid. Odorless with a very low vapor pressure.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Ethylene glycol dinitrate (EGDN [CAS: 628-96-6]): Causes vasodilation similar to other nitrite compounds. Headache, hypotension, flushing, palpitation, delirium, and CNS depression may occur. Well absorbed by all routes. Tolerance and dependence may develop to vasodilatory effects; cessation after repeated exposures may cause angina pectoris. Weak inducer of methemoglobinemia (see p 261).	0.05 ppm, S	75 mg/m ³		Yellow oily liquid. Vapor pressure is 0.05 mm Hg at 20°C (68°F). Explosive.
Ethyleneimine (CAS: 151-56-4): Strong caustic. Highly irritating upon direct contact; severe burns may result. Vapors irritating to eyes and respiratory tract; delayed-onset pulmonary edema may occur. Overexposures have resulted in nausea, vomiting, headache, and dizziness. Well absorbed dermally. A carcinogen in animals.	0.5 ppm, S, A3 OSHA CA NIOSH CA	100 ppm	4 3 3	Colorless liquid with an amine-like odor. Vapor pressure is 160 mm Hg at 20°C (68°F). Flammable. Contains inhibitor to prevent explosive self-polymerization.
Ethylene oxide (CAS: 75-21-8): Highly irritating upon direct contact. Vapors irritating to eyes and respiratory tract; delayed pulmonary edema has been reported. A CNS depressant at very high levels. Chronic overexposures can cause peripheral neuropathy and possible permanent CNS impairment. Adverse effects on fetal development and fertility in test animals and limited evidence in humans. A carcinogen in animal studies. Limited evidence of carcinogenicity in humans (IARC 2A). See also p 199.	1 ppm, A2 OSHA CA NIOSH CA	800 ppm ERPG-2: 50 ppm ERPG-3: 500 ppm	3 4 3	Colorless. Highly flammable. Ether-like odor is a poor warning property. Important source of exposures is sterilization operations in health care industry.
Ethyl ether (diethyl ether [CAS: 60-29-7]): Vapors irritating to eyes and respiratory tract. A CNS depressant and anesthetic agent; tolerance may develop to this effect. Overexposure produces nausea, headache, dizziness, anesthesia, and respiratory arrest. Evidence for adverse effects on fetal development in test animals.	400 ppm	1900 ppm [LEL]	1 4 1	Colorless liquid. Ether-like odor occurs at low levels and is a good warning property. Vapor pressure is 439 mm Hg at 20°C (68°F). Highly flammable.

Ethyl formate (CAS: 109-94-4): Slightly irritating to the skin upon direct contact. Vapors mildly irritating to eyes and upper respiratory tract. In test animals, very high levels caused rapid narcosis and pulmonary edema.	100 ppm	1500 ppm	2 3 0	Colorless liquid. Fruity odor and irritation occur near the TLV and are good warning properties. Vapor pressure is 194 mm Hg at 20°C (68°F). Highly flammable.
Ethyl mercaptan (ethanethiol [CAS: 75-08-1]): Vapors mildly irritating to eyes and respiratory tract. Respiratory paralysis and CNS depression at very high levels. Headache, nausea, and vomiting likely owing to strong odor.	0.5 ppm	500 ppm	2 4 0	Colorless liquid. Penetrating, offensive, mercaptan-like odor. Vapor pressure is 442 mm Hg at 20°C (68°F).
N-Ethylmorpholine (CAS: 100-74-3): Irritating to eyes upon direct contact. Vapors irritating to eyes and respiratory tract. Workers exposed to levels near the TLV reported drowsiness and temporary visual disturbances, including corneal edema. Animal testing suggests potential for skin absorption.	5 ppm, S	100 ppm	2 3 0	Colorless liquid with ammonia-like odor. Vapor pressure is 5 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include oxides of nitrogen.
Ethyl silicate (tetraethyl orthosilicate, tetraethoxysilane [CAS: 78-10-4]): Irritating upon direct contact. Vapors irritating to eyes and respiratory tract. All human effects noted at vapor exposures above the odor threshold. In subchronic animal testing, high vapor levels produced liver, lung, and kidney damage, and delayed-onset pulmonary edema.	10 ppm	700 ppm ERPG-1: 25 ppm ERPG-2: 100 ppm ERPG-3: 300 ppm	2 2 0	Colorless liquid. Faint alcohol-like odor and irritation are good warning properties. Vapor pressure is 2 mm Hg at 20°C (68°F). Flammable.
Fenamiphos (ethyl 3-methyl-4-[methylthio]-phenyl[1-methylethyl]phosphoramidate [CAS: 22224-92-6]): An organophosphate-type cholinesterase inhibitor (see p 291). Well absorbed dermally.	0.1 mg/m ³ , S			Tan, waxy solid. Vapor pressure is 0.000001 mm Hg at 30°C (86°F).
Fensulfothion (O,O-diethyl O-[4-(methyl-sulfinyl)phenyl]phosphorothioate [CAS: 115-90-2]): An organophosphate-type cholinesterase inhibitor (see p 291).	0.1 mg/m ³			Brown liquid.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Fenthion (<i>O,O</i>-dimethyl <i>O</i>-[3-methyl-4-(methylthio)phenyl]phosphorothioate [CAS: 55-38-9]): An organophosphate-type cholinesterase inhibitor (see p 291). Highly lipid soluble; toxicity may be prolonged. Dermal absorption is rapid.	0.2 mg/m ³ , S			Yellow to tan viscous liquid with a mild garlic-like odor. Vapor pressure is 0.00003 mm Hg at 20°C (68°F).
Ferbam (ferric dimethyldithiocarbamate [CAS: 14484-64-1]): Thiocarbamates do not act through cholinesterase inhibition. Dusts irritating upon direct contact; causes dermatitis in persons sensitized to sulfur. Dusts are mild respiratory tract irritants. Limited evidence for adverse effects on fetal development in test animals.	10 mg/m ³	800 mg/m ³		Odorless, black solid. Vapor pressure is negligible at 20°C (68°F). Thermal-breakdown products include oxides of nitrogen and sulfur. Used as a fungicide.
Ferrovandium dust (CAS: 12604-58-9): Mild irritant of eyes and respiratory tract.	1 mg/m ³	500 mg/m ³		Odorless, dark-colored powders.
Fluoride dust (as fluoride): Irritating to eyes and respiratory tract. Workers exposed to levels 10 mg/m ³ suffered nasal irritation and bleeding. Lower-level exposures have produced nausea and eye and respiratory tract irritation. Chronic overexposures may result in skin rashes. Fluorosis, a bone disease with chronic high-level fluoride ingestion, is not associated with occupational dust inhalation. See also p 200.	2.5 mg/m ³ (as F)	250 mg/m ³ (as F)		Appearance varies with the compound. Sodium fluoride is a colorless to blue solid.
Fluorine (CAS: 7782-41-4): Rapidly reacts with moisture to form ozone and hydrofluoric acid. The gas is a severe eye, skin, and respiratory tract irritant; severe penetrating burns and pulmonary edema have resulted. Systemic hypocalcemia can occur with fluorine or hydrogen fluoride exposure. See also p 221.	1 ppm	25 ppm ERPG-1: 0.5 ppm ERPG-2: 5.0 ppm ERPG-3: 20 ppm	4 0 4 W	Pale yellow gas. Sharp odor is a poor warning property. Highly reactive; will ignite many oxidizable materials. Uses include rocket fuel oxidizer.

Fonofos (O-ethyl S-phenyl ethylphosphono-thiolothionate, Dyfonate [CAS: 944-22-9]): An organophosphate-type cholinesterase inhibitor (see p 291). Highly toxic; oral toxicity in test animals ranged from 3 to 13 mg/kg for rats, and rabbits died after eye instillation.	0.1 mg/m ³ , S				Vapor pressure is 0.00021 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of sulfur.
Formaldehyde (formic aldehyde, methanal, HCHO, formalin [CAS: 50-00-0]): Highly irritating to eyes upon direct contact; severe burns result. Irritating to skin; may cause a sensitization dermatitis. Vapors highly irritating to eyes and respiratory tract. Sensitization may occur. A carcinogen in test animals (IARC 2A). See also p 207.	0.3 ppm (C), SEN, A2 OSHA CA NIOSH CA	20 ppm ERPG-1: 1 ppm ERPG-2: 10 ppm ERPG-3: 25 ppm	3 4 0 (gas) 3 2 0 (formalin)		Colorless gas with a suffocating odor. Combustible. Formalin (15% methanol) solutions are flammable.
Formamide (methanamide [CAS: 75-12-7]): In animal tests, mildly irritating upon direct contact. Adverse effects on fetal development in test animals at very high doses.	10 ppm, S		2 1 –		Clear, viscous liquid. Odorless. Vapor pressure is 2 mm Hg at 70°C (158°F). Combustible. Thermal-breakdown products include oxides of nitrogen.
Formic acid (CAS: 64-18-6): Acid is corrosive; severe burns may result from contact of eyes and skin with concentrated acid. Vapors highly irritating to eyes and respiratory tract. Ingestion may produce severe metabolic acidosis (see methanol, p 260).	5 ppm	30 ppm	3 2 0		Colorless liquid. Pungent odor and irritation occur near the TLV and are adequate warning properties. Vapor pressure is 30 mm Hg at 20°C (68°F). Combustible.
Furfural (bran oil [CAS: 98-01-1]): Highly irritating upon direct contact; burns may result. Vapors highly irritating to eyes and respiratory tract; pulmonary edema may result. Animal studies indicate the liver is a target organ. Hyperreflexia and convulsions occur at large doses in test animals.	2 ppm, S, A3	100 ppm ERPG-1: 2 ppm ERPG-2: 10 ppm ERPG-3: 100 ppm	3 2 0		Colorless to light brown liquid. Almond-like odor occurs below the TLV and is a good warning property. Vapor pressure is 2 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include oxides of nitrogen.
Furfuryl alcohol (CAS: 98-00-0): Dermal absorption occurs. Vapors irritating to eyes and respiratory tract. A CNS depressant at high air levels.	10 ppm, S	75 ppm	1 2 1		Clear, colorless liquid. Upon exposure to light and air, changes color to red or brown. Vapor pressure is 0.53 mm Hg at 20°C (68°F). Combustible.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Gasoline (CAS: 8006-61-9): Although exact composition varies, the acute toxicity of all gasolines is similar. Vapors irritating to eyes and respiratory tract at high levels. A CNS depressant; symptoms include incoordination, dizziness, headaches, and nausea. Benzene (generally < 1%) is one significant chronic health hazard. Other additives such as ethylene dibromide and tetraethyl and tetramethyl lead are present in low amounts and may be absorbed through the skin. Very limited evidence for carcinogenicity in test animals. See also p 219.	300 ppm, A3		1 3 0	Clear to amber liquid with a characteristic odor. Highly flammable. Gasoline is sometimes inappropriately used as a solvent. Substance abuse via inhalation has been reported.
Germanium tetrahydride (CAS: 7782-65-2): A hemolytic agent with effects similar to but less potent than arsine in animals. Symptoms include abdominal pain, hematuria, anemia, and jaundice.	0.2 ppm			Colorless gas. Highly flammable.
Glutaraldehyde (1,5-pentandial (CAS: 111-30-8)): The purity and therefore the toxicity of glutaraldehyde varies widely. Allergic dermatitis may occur. Highly irritating on contact; severe burns may result. Vapors highly irritating to eyes and respiratory tract; respiratory sensitization may occur. In animal studies, the liver is a target organ at high doses.	0.05 ppm (C), SEN			Colorless solid crystals. Vapor pressure is 0.0152 mm Hg at 20°C (68°F). Can undergo hazardous self-polymerization. Commonly used as a sterilizing agent in medical settings.
Glycidol (2,3-epoxy-1-propanol (CAS: 556-52-5)): Highly irritating to eyes on contact; burns may result. Moderately irritating to skin and respiratory tract. Evidence for carcinogenicity and testicular toxicity in test animals.	2 ppm, A3	150 ppm		Colorless liquid. Vapor pressure is 0.9 mm Hg at 25°C (77°F). Combustible.
Hafnium (CAS: 7440-58-6): Based on animal studies, dusts are mildly irritating to eyes and skin. Liver injury may occur at very high doses.	0.5 mg/m ³	50 mg/m ³		The metal is a gray solid. Other compounds vary in appearance.

Heptachlor (CAS: 76-44-8): CNS convulsant. Skin absorption is rapid and has caused convulsions and death. Hepatotoxic. Stored in fatty tissues. Limited evidence for adverse effects on fetal development in test animals at high doses. A carcinogen in test animals. See also p 161.	0.05 mg/m ³ , S, A3	35 mg/m ³		White or light tan, waxy solid with a camphor-like odor. Vapor pressure is 0.0003 mm Hg at 20°C (68°F). Thermal-breakdown products include hydrogen chloride. Not combustible. Pesticide use banned by EPA in 1988.
n-Heptane (CAS: 142-82-5): Vapors only slightly irritating to eyes and respiratory tract. May cause euphoria, vertigo, CNS depression, and cardiac arrhythmias at high levels.	400 ppm	750 ppm	1 3 0	Colorless clear liquid. Mild gasoline-like odor occurs below the TLV and is a good warning property. Vapor pressure is 40 mm Hg at 20°C (68°F). Flammable.
Hexachlorobutadiene (CAS: 87-68-3): Based on animal studies, rapid dermal absorption is expected. The kidney is the major target organ. A carcinogen in test animals (IARC 3).	0.02 ppm, S, A3	ERPG-1: 3 ppm ERPG-2: 10 ppm ERPG-3: 30 ppm	2 1 1	Heavy, colorless liquid. Thermal-breakdown products include hydrogen chloride and phosgene.
Hexachlorocyclopentadiene (CAS: 77-47-4): Vapors extremely irritating to eyes and respiratory tract; lacrimation, salivation. In animal studies, a potent kidney and liver toxin. At higher levels the brain, heart, and adrenal glands were affected. Tremors occurred at high doses.	0.01 ppm			Yellow to amber liquid with a pungent odor. Vapor pressure is 0.08 mm Hg at 20°C (68°F). Not combustible.
Hexachloroethane (perchloroethane [CAS: 67-72-1]): Hot fumes irritating to eyes, skin, and mucous membranes. Based on animal studies, causes CNS depression and kidney and liver injury at high doses. Limited evidence of carcinogenicity in test animals (IARC 3).	1 ppm, S, A3 NIOSH CA	300 ppm		White solid with a camphor-like odor. Vapor pressure is 0.22 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include phosgene, chlorine gas, and hydrogen chloride.
Hexachloronaphthalene (Halowax 1014 [CAS: 1335-87-1]): Based on workplace experience, a potent toxin causing severe chloracne and severe, occasionally fatal, liver injury. Skin absorption can occur.	0.2 mg/m ³ , S	2 mg/m ³		Light yellow solid with an aromatic odor. Vapor pressure is less than 1 mm Hg at 20°C (68°F). Not combustible.
Hexamethylphosphoramide (CAS: 680-31-9): Low-level exposures produced nasal cavity cancer in rats (IARC 2B). Adverse effects on the testes in test animals.	S, A3			Colorless liquid with an aromatic odor. Vapor pressure is 0.07 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of nitrogen.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <— 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
<i>n</i>-Hexane (normal hexane [CAS: 110-54-3]): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant at high levels, producing headache, dizziness, and gastrointestinal upset. Occupational overexposures have resulted in peripheral neuropathies. Methyl ethyl ketone potentiates this toxicity. Testicular toxicity in animal studies.	50 ppm, S	1100 ppm [LEL]	1 3 0	Colorless, clear liquid with a mild gasoline odor. Vapor pressure is 124 mm Hg at 20°C (68°F). Highly flammable.
Hexane isomers (other than <i>n</i>-hexane, isohexane, 2,3-dimethylbutane): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant at high levels, producing headache, dizziness, and gastrointestinal upset.	500 ppm			Colorless liquids with a mild petroleum odor. Vapor pressures are high at 20°C (68°F). Highly flammable.
<i>sec</i>-Hexyl acetate (1,3-dimethylbutyl acetate [CAS: 108-84-9]): At low levels, vapors irritating to eyes and respiratory tract. Based on animal studies, a CNS depressant at high levels.	50 ppm	500 ppm	1 2 0	Colorless liquid. Unpleasant fruity odor and irritation are both good warning properties. Vapor pressure is 4 mm Hg at 20°C (68°F). Flammable.
Hexylene glycol (2-methyl-2,4-pentanediol [CAS: 107-41-5]): Irritating upon direct contact; vapors irritating to eyes and respiratory tract. A CNS depressant at very high doses in animal studies.	25 ppm (C)		1 1 0	Liquid with a faint sweet odor. Vapor pressure is 0.05 mm Hg at 20°C (68°F). Combustible.
Hydrazine (diamine [CAS: 302-01-2]): Corrosive upon direct contact; severe burns result. Vapors extremely irritating to eyes and respiratory tract; pulmonary edema may occur. Highly hepatotoxic. A convulsant and hemolytic agent. Kidneys are also target organs. Well absorbed by all routes. A carcinogen in test animals (IARC 2B).	0.01 ppm, S, A3 NIOSH CA	50 ppm ERPG-1: 0.5 ppm ERPG-2: 5 ppm ERPG-3: 30 ppm	3 3 3 (vapors explosive)	Colorless, fuming, viscous liquid with an amine odor. Vapor pressure is 10 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include oxides of nitrogen. Used as a rocket fuel and in some military jet systems.
Hydrogen bromide (HBr [CAS: 10035-10-6]): Direct contact with concentrated solutions may cause corrosive acid burns. Vapors highly irritating to eyes and respiratory tract; pulmonary edema may result.	3 ppm (C)	30 ppm	3 0 0	Colorless gas or pressurized liquid. Acrid odor and irritation occur near the TLV and are adequate warning properties. Not combustible.

Hydrogen chloride (muriatic acid, HCl [CAS: 7647-01-0]): Direct contact with concentrated solutions may cause corrosive acid burns. Vapors highly irritating to eyes and respiratory tract; pulmonary edema has resulted.	5 ppm (C)	50 ppm ERPG-1: 3 ppm ERPG-2: 20 ppm ERPG-3: 150 ppm	3 0 1	Colorless gas with a pungent, choking odor. Irritation occurs near the TLV and is a good warning property. Not combustible.
Hydrogen cyanide (hydrocyanic acid, prussic acid, HCN [CAS: 74-90-8]): A rapidly acting, potent metabolic asphyxiant that inhibits cytochrome oxidase and stops cellular respiration. See also p 177.	4.7 ppm (C), S	50 ppm ERPG-1: 10 ppm ERPG-3: 25 ppm	4 4 2 (vapors extremely toxic)	Colorless to pale blue liquid or colorless gas with a sweet, bitter almond smell that is an inadequate warning property even for those sensitive to it. Vapor pressure is 620 mm Hg at 20°C (68°F). Cyanide salts will release HCN gas with exposure to acids or heat.
Hydrogen fluoride (hydrofluoric acid, HF [CAS: 7664-39-3]): Produces severe, penetrating burns to eyes, skin, and deeper tissues upon direct contact with solutions. Onset of pain and erythema may be delayed as much as 12–16 hours. As a gas, highly irritating to the eyes and respiratory tract; pulmonary edema has resulted. Severe hypocalcemia may occur with overexposure. See p 221.	3 ppm (C) (as F)	30 ppm ERPG-1: 2 ppm ERPG-2: 20 ppm ERPG-3: 50 ppm	4 0 1	Colorless fuming liquid or gas. Irritation occurs at levels below the TLV and is an adequate warning property. Vapor pressure is 760 mm Hg at 20°C (68°F). Not combustible. Commercial rust-removing products may contain HF, but generally at lower concentrations (< 10%).
Hydrogen peroxide (CAS: 7722-84-1): A strong oxidizing agent. Direct contact with concentrated solutions can produce severe eye damage and skin irritation, including erythema and vesicle formation. Vapors irritating to eyes, skin, mucous membranes, and respiratory tract. See also p 109.	1 ppm, A3	75 ppm ERPG-1: 10 ppm ERPG-2: 50 ppm ERPG-3: 100 ppm	2 0 3 Ox (60% or greater) 2 0 1 Ox (40–60%)	Colorless liquid with a slightly sharp, distinctive odor. Vapor pressure is 5 mm Hg at 30°C (86°F). Because of instability, usually found in aqueous solutions (3% for home use, higher in some “health food” products and in industry). Not combustible but a very powerful oxidizing agent.
Hydrogen selenide (CAS: 7783-07-5): Vapors extremely irritating to eyes and respiratory tract. Systemic symptoms from low-level exposure include nausea and vomiting, fatigue, metallic taste in mouth, and a garlicky breath odor. Animal studies indicate hepatotoxicity.	0.05 ppm	1 ppm ERPG-1: 0.2 ppm ERPG-3: 2 ppm		Colorless gas. The strongly offensive odor and irritation occur only at levels far above the TLV and are poor warning properties. Flammable. Water-reactive.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <— 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Hydrogen sulfide (sewer gas [CAS: 7783-06-4]): Vapors irritating to eyes and respiratory tract. At higher levels, a potent, rapid systemic toxin causing cellular asphyxia and death. Systemic effects of low-level exposure include headache, cough, nausea, and vomiting. See also p 224.	10 ppm	100 ppm ERPG-1: 0.1 ppm ERPG-2: 30 ppm ERPG-3: 100 ppm	4 4 0	Colorless gas. Although the strong rotten egg odor can be detected at very low levels, olfactory fatigue occurs. Odor is therefore a poor warning property. Flammable. Produced by the decay of organic material as may occur in sewers, manure pits, and fish processing. Fossil fuel production also may generate the gas.
Hydroquinone (1,4-dihydroxybenzene [CAS: 123-31-9]): Highly irritating to eyes upon direct contact. Chronic occupational exposures may cause partial discoloration and opacification of the cornea. Systemic effects reported result from ingestion and include tinnitus, headache, dizziness, gastrointestinal upset, CNS excitation, and skin depigmentation. May cause methemoglobinemia (see p 261). Limited evidence of carcinogenicity in test animals.	2 mg/m ³ , A3	50 mg/m ³	2 1 0	White solid crystals. Vapor pressure is less than 0.001 mm Hg at 20°C (68°F). Combustible.
2-Hydroxypropyl acrylate (HPA [CAS: 999-61-1]): Highly irritating upon direct contact; severe burns may result. Vapors highly irritating to eyes and respiratory tract. Based on structural analogies, compounds containing the acrylate moiety may be carcinogens.	0.5 ppm, S, SEN		3 1 2	Combustible liquid.
Indene (CAS: 95-13-6): Repeated direct contact with the skin produced a dry dermatitis but no systemic effects. Vapors likely irritating to eyes and respiratory tract. Based on animal studies, high air levels may cause liver and kidney damage.	10 ppm			Colorless liquid.
Indium (CAS: 7440-74-6): Based on animal studies, the soluble salts are extremely irritating to eyes upon direct contact. Dusts irritating to eyes and respiratory tract. In animal studies, indium compounds are highly toxic parenterally but much less toxic orally.	0.1 mg/m ³			Appearance varies with the compound. The elemental metal is a silver-white lustrous solid.

Iodine (CAS: 7553-56-2): Extremely irritating upon direct contact; severe burns result. Vapors extremely irritating and corrosive to eyes and respiratory tract. Rarely, a skin sensitizer. Medicinal use of iodine-containing drugs has been associated with fetal goiter, a potentially life-threatening condition for the fetus or infant. Iodine causes adverse effects on fetal development in test animals. See also p 226.	0.1 ppm (C)	2 ppm ERPG-1: 0.1 ppm ERPG-2: 0.5 ppm ERPG-3: 5 ppm		Violet-colored solid crystals. Sharp, characteristic odor is a poor warning property. Vapor pressure is 0.3 mm Hg at 20°C (68°F). Not combustible.
Iron oxide fume (CAS: 1309-37-1): Fumes and dusts can produce a benign pneumoconiosis (siderosis) with shadows on chest radiographs.	5 mg/m ³ (as Fe)	2500 mg/m ³ (as Fe)		Red-brown fume with a metallic taste. Vapor pressure is negligible at 20°C (68°F).
Iron pentacarbonyl (iron carbonyl [CAS: 13463-40-6]): Acute toxicity resembles that of nickel carbonyl. Inhalation of vapors can cause lung and systemic injury without warning signs. Symptoms of overexposure include headache, nausea and vomiting, and dizziness. Symptoms of severe poisoning are fever, extreme weakness, and pulmonary edema; effects may be delayed for up to 36 hours.	0.1 ppm			Colorless to yellow viscous liquid. Vapor pressure is 40 mm Hg at 30.3°C (86.5°F). Highly flammable.
Isoamyl acetate (banana oil, 3-methyl butyl acetate [CAS: 123-92-2]): May be irritating to skin upon prolonged contact. Vapors mildly irritating to eyes and respiratory tract. Symptoms in men exposed to 950 ppm for 0.5 hour included headache, weakness, dyspnea, and irritation of the nose and throat. A CNS depressant at high doses in test animals.	100 ppm	1000 ppm	1 3 0	Colorless liquid. Banana-like odor and irritation occur at low levels and are good warning properties. Vapor pressure is 4 mm Hg at 20°C (68°F). Flammable.
Isoamyl alcohol (3-methyl-1-butanol [CAS: 123-51-3]): Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels.	100 ppm	500 ppm	1 2 0	Colorless liquid. Irritating alcohol-like odor and irritation are good warning properties. Vapor pressure is 2 mm Hg at 20°C (68°F). Flammable.
Isobutyl acetate (2-methylpropyl acetate [CAS: 110-19-0]): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant at high levels.	150 ppm	1300 ppm [LEL]	1 3 0	Colorless liquid. Pleasant fruity odor is a good warning property. Vapor pressure is 13 mm Hg at 20°C (68°F). Flammable.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Isobutyl alcohol (2-methyl-1 propanol [CAS: 78-83-1]): A CNS depressant at high levels.	50 ppm	1600 ppm	1 3 0	Colorless liquid. Mild characteristic odor is a good warning property. Vapor pressure is 9 mm Hg at 20°C (68°F). Flammable.
Isophorone (trimethylcyclohexenone [CAS: 78-59-1]): Vapors irritating to eyes and respiratory tract. Workers exposed to 5–8 ppm complained of fatigue and malaise after 1 month. Higher exposures result in nausea, headache, dizziness, and a feeling of suffocation at 200–400 ppm. Limited evidence for adverse effects on fetal development in test animals.	5 ppm (C), A3	200 ppm	2 2 0 W	Colorless liquid with a camphor-like odor. Vapor pressure is 0.2 mm Hg at 20°C (68°F). Flammable.
Isophorone diisocyanate (CAS: 4098-71-9): Based on animal studies, extremely irritating upon direct contact; severe burns may result. By analogy with other isocyanates, vapors or mists likely to be potent respiratory sensitizers, causing asthma. See also p 232.	0.005 ppm		2 2 1 W	Colorless to pale yellow liquid. Vapor pressure is 0.0003 mm Hg at 20°C (68°F). Possible thermal-breakdown products include oxides of nitrogen and hydrogen cyanide.
2-Isopropoxyethanol (isopropyl Cellosolve, ethylene glycol mono-isopropyl ether [CAS: 109-59-1]): Defatting agent causing dermatitis. May cause hemolysis.	25 ppm, S			Clear colorless liquid with a characteristic odor.
Isopropyl acetate (CAS: 108-21-4): Vapors irritating to the eyes and respiratory tract. A weak CNS depressant.	250 ppm	1800 ppm	1 3 0	Colorless liquid. Fruity odor and irritation are good warning properties. Vapor pressure is 43 mm Hg at 20°C (68°F). Flammable.
Isopropyl alcohol (isopropanol, 2-propanol [CAS: 67-63-0]): Vapors produce mild eye and respiratory tract irritation. High exposures can produce CNS depression. See also p 234.	400 ppm	2000 ppm [LEL]	1 3 0	Rubbing alcohol. Sharp odor and irritation are adequate warning properties. Vapor pressure is 33 mm Hg at 20°C (68°F). Flammable.

Isopropylamine (2-aminopropane [CAS: 75-31-0]): Corrosive upon direct contact; severe burns may result. Vapors highly irritating to the eyes and respiratory tract. Exposure to vapors can cause transient corneal edema.	5 ppm	750 ppm	3 4 0	Colorless liquid. Strong ammonia odor and irritation are good warning properties. Vapor pressure is 478 mm Hg at 20°C (68°F). Highly flammable. Thermal-breakdown products include oxides of nitrogen.
Isopropyl ether (diisopropyl ether [CAS: 108-20-3]): A skin irritant upon prolonged contact with liquid. Vapors mildly irritating to the eyes and respiratory tract. A CNS depressant.	250 ppm	1400 ppm [LEL]	1 3 1	Colorless liquid. Offensive and sharp ether-like odor and irritation are good warning properties. Vapor pressure is 119 mm Hg at 20°C (68°F). Highly flammable. Contact with air causes formation of explosive peroxides.
Isopropyl glycidyl ether (CAS: 4016-14-2): Irritating upon direct contact. Allergic dermatitis may occur. Vapors irritating to eyes and respiratory tract. In animals, A CNS depressant at high oral doses; chronic exposures produced liver injury. Some glycidyl ethers possess hemato-poietic and testicular toxicity.	50 ppm	400 ppm		Flammable. Vapor pressure is 9.4 mm Hg at 25°C (77°F).
Kepone (chlordecone [CAS: 143-50-0]): Neurotoxin; overexposure causes slurred speech, memory impairment, incoordination, weakness, tremor, and convulsions. Causes infertility in males. Hepato-toxic. Well absorbed by all routes. A carcinogen in test animals. See also p 161.	NIOSH CA			A solid. Not manufactured in the US since 1978.
Ketene (ethenone [CAS: 463-51-4]): Vapors extremely irritating to the eyes and respiratory tract; pulmonary edema may result and can be delayed for up to 72 hours. Toxicity similar to that of phosgene (see p 305), of which it is the nonchlorinated analog, in both magnitude and time course.	0.5 ppm	5 ppm		Colorless gas with a sharp odor. Polymerizes readily. Acetylating agent. Water-reactive.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Lead (inorganic compounds, dusts, and fumes): Toxic to CNS and peripheral nerves, kidneys, and hematopoietic system. Toxicity may result from acute or chronic exposures. Inhalation and ingestion are the major routes of absorption. Symptoms and signs include abdominal pain, anemia, mood or personality changes, and peripheral neuropathy. Encephalopathy may develop with high blood levels. Adversely affects reproductive functions in men and women. Adverse effects on fetal development in test animals. Such inorganic lead compounds are carcinogenic in animal studies (IARC 2B). See also p 238.	0.05 mg/m ³ , A3	100 mg/m ³ (as Pb)		The elemental metal is dark gray. Vapor pressure is low, about 2 mm Hg at 1000°C (1832°F). Major industrial sources include smelting, battery manufacture, radiator repair, and glass and ceramic processing.
Lead arsenate (CAS: 10102-48-4): Most common acute poisoning symptoms are caused by arsenic, with lead being responsible for chronic toxicity. Symptoms include abdominal pain, headache, vomiting, diarrhea, nausea, itching, and lethargy. Liver and kidney damage may also occur. See both lead and arsenic, pp 238 and 115.	0.15 mg/m ³			White powder often dyed pink. Not combustible.
Lead chromate (chrome yellow [CAS: 7758-97-6]): Toxicity may result from both the chromium and the lead components. Lead chromate is a suspect human carcinogen owing to the carcinogenicity of hexavalent chromium and inorganic lead compounds. See both lead and hexavalent chromium, pp 238 and 167.	0.05 mg/m ³ (as Pb) 0.012 mg/m ³ (as Cr), A2			Yellow pigment in powder or crystal form.
Lindane (gamma-hexachlorocyclohexane [CAS: 58-89-9]): A CNS stimulant and convulsant. Vapors irritating to the eyes and mucous membranes and produce severe headaches and nausea. Well absorbed by all routes. Animal feeding studies have resulted in lung, liver, and kidney damage. May injure bone marrow. Equivocal evidence of carcinogenicity in test animals. See also p 161.	0.5 mg/m ³ , S, A3	50 mg/m ³		White crystalline substance with a musty odor if impure. Not combustible. Vapor pressure is 0.0000094 mm Hg at 20°C (68°F). Use as a pesticide restricted by EPA to certified applicators. Still available (1% lotion or shampoo) as a scabicide, although safer alternatives exist.

Lithium hydride (CAS: 7580-67-8): Strong vesicant and alkaline corrosive. Extremely irritating upon direct contact; severe burns result. Dusts extremely irritating to eyes and respiratory tract; pulmonary edema may develop. Symptoms of systemic toxicity include nausea, tremors, confusion, blurring of vision, and coma.	0.025 mg/m ³	0.5 mg/m ³ ERPG-1: 0.025 mg/m ³ ERPG-2: 0.1 mg/m ³ ERPG-3: 0.5 mg/m ³	3 2 2 W	Off-white, translucent solid powder that darkens on exposure. Odorless. Very water-reactive, yielding highly flammable hydrogen gas and caustic lithium hydroxide. Finely dispersed powder may ignite spontaneously.
LPG (liquefied petroleum gas [CAS: 68476-85-7]): A simple asphyxiant and possible CNS depressant. Flammability dangers greatly outweigh toxicity concerns. See also hydrocarbons, p 219.	1000 ppm	2000 ppm [LEL]		Colorless gas. An odorant is usually added as the pure product is odorless. Highly flammable.
Magnesium oxide fume (CAS: 1309-48-4): Slightly irritating to eyes and upper respiratory tract.	10 mg/m ³	750 mg/m ³		White fume.
Malathion (O,O-dimethyl dithiophosphate of diethyl mercaptosuccinate [CAS: 121-75-5]): An organophosphate-type cholinesterase inhibitor (see p 291). May cause skin sensitization. Absorbed dermally.	10 mg/m ³ , S	250 mg/m ³		Colorless to brown liquid with mild skunk-like odor. Vapor pressure is 0.00004 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of sulfur and phosphorus.
Maleic anhydride (2,5-furandione [CAS: 108-31-6]): Extremely irritating upon direct contact; severe burns may result. Vapors and mists extremely irritating to eyes, skin, and respiratory tract. A skin and respiratory tract sensitizer (asthma).	0.1 ppm	10 mg/m ³	3 1 1	Colorless to white solid. Strong, penetrating odor. Eye irritation occurs at the TLV and is an adequate warning property. Vapor pressure is 0.16 mm Hg at 20°C (68°F). Combustible.
Manganese (CAS: 7439-96-5): Chronic overexposure results in a CNS toxicity manifested as psychosis, which may be followed by a progressive toxicity similar to parkinsonism (manganism). See also p 251.	0.2 mg/m ³ (elemental and inorganic compounds, as Mn)	500 mg/m ³ (Mn compounds, as Mn)		Elemental metal is a gray, hard, brittle solid. Other compounds vary in appearance. Exposure occurs in mining and milling of the metal, in ferromanganese steel production, and through electric arc welding.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Mercury (quicksilver [CAS: 7439-97-6]): Acute exposures to high vapor levels reported to cause toxic pneumonitis and pulmonary edema. Well absorbed by inhalation. Skin contact can produce irritation and sensitization dermatitis. Mercury salts but not metallic mercury are primarily toxic to the kidneys by acute ingestion. High acute or chronic overexposures can result in CNS toxicity (erythrism), chronic renal disease, brain injury, and peripheral neuropathies. Some inorganic mercury compounds have adverse effects on fetal development in test animals. See also p 254.	0.025 mg/m ³ (inorganic and elemental), S	10 mg/m ³ ERPG-2: 0.2 ppm ERPG-3: 2 ppm		Elemental metal is a dense, silvery liquid. Odorless. Vapor pressure is 0.0012 mm Hg at 20°C (68°F). Sources of exposure include small-scale gold refining operations by hobbyists and mercury-containing instruments.
Mercury, alkyl compounds (dimethylmercury, diethyl mercury, ethylmercuric chloride, phenylmercuric acetate): Well absorbed by all routes. Slow excretion may allow accumulation to occur. Readily crosses blood-brain barrier and placenta. Can cause kidney damage, organic brain disease, and peripheral neuropathy. Some compounds are extremely toxic. Methylmercury is teratogenic in humans. See also p 254.	0.01 mg/m ³ (alkyl compounds, as Hg), S	2 mg/m ³ (as Hg)		Colorless liquids or solids. Many alkyl compounds have a disagreeable odor. Inorganic mercury can be converted to alkyl mercury compounds in the environment. Can accumulate in food chain. Phenylmercuric acetate use as a fungicide was banned from indoor paints in 1990.
Mesityl oxide (4-methyl-3-penten-2-one [CAS: 141-79-7]): Causes dermatitis upon prolonged contact. Vapors very irritating to eyes and respiratory tract. Based on animal tests, a CNS depressant and injures kidney and liver at high levels.	15 ppm	1400 ppm [LEL]	2 3 1	Colorless viscous liquid with a peppermint-like odor. Irritation is an adequate warning property. Vapor pressure is 8 mm Hg at 20°C (68°F). Flammable. Readily forms peroxides.
Methacrylic acid (2-methylpropenoic acid [CAS: 79-41-4]): Corrosive upon direct contact; severe burns result. Vapors highly irritating to eyes and, possibly, respiratory tract. Based on structural analogies, compounds containing the acrylate moiety may be carcinogens.	20 ppm		3 2 2	Liquid with an acrid, disagreeable odor. Vapor pressure is less than 0.1 mm Hg at 20°C (68°F). Combustible. Polymerizes above 15°C (59°F), emitting toxic gases.

Methomyl (S-methyl N[(methylcarbamoyl)oxy] thioacetimidate, Lannate, Nudrin [CAS: 16752-77-5]): A carbamate-type cholinesterase inhibitor (see p 291).	2.5 mg/m ³			A slight sulfur odor. Vapor pressure is 0.00005 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of nitrogen and sulfur.
Methoxychlor (dimethoxy-DDT, 2,2-bis(p-methoxyphenol)-1,1,1-trichloroethane [CAS: 72-43-5]): A convulsant at very high doses in test animals. Limited evidence for adverse effects on male reproduction and fetal development in test animals at high doses. See also p 161.	10 mg/m ³	5000 mg/m ³		Colorless to tan solid with a mild fruity odor. Appearance and some hazardous properties vary with the formulation. Vapor pressure is very low at 20°C (68°F).
2-Methoxyethanol (ethylene glycol monomethyl ether, methyl cellosolve [CAS: 109-86-4]): Workplace overexposures have resulted in depression of the hematopoietic system and encephalopathy. Symptoms include disorientation, lethargy, and anorexia. Well absorbed dermally. Animal testing revealed testicular atrophy and teratogenicity at low doses. Overexposure associated with reduced sperm counts in workers. See also p 194.	5 ppm, S	200 ppm	2 2 0	Clear, colorless liquid with a faint odor. Vapor pressure is 6 mm Hg at 20°C (68°F). Flammable.
2-Methoxyethyl acetate (ethylene glycol monomethyl ether acetate, methyl cellosolve acetate [CAS: 110-49-6]): Mildly irritating to eyes upon direct contact. Dermally well absorbed. Vapors slightly irritating to the respiratory tract. A CNS depressant at high levels. Based on animal studies, may cause kidney damage, leukopenia, testicular atrophy, and birth defects. See also p 194.	5 ppm, S	200 ppm	1 2 -	Colorless liquid with a mild, pleasant odor. Flammable.
Methyl acetate (CAS: 79-20-9): Vapors moderately irritating to the eyes and respiratory tract. A CNS depressant at high levels. Hydrolyzed to methanol in the body with possible consequent toxicity similar to that of methanol (see p 260).	200 ppm	3100 ppm [LEL]	1 3 0	Colorless liquid with a pleasant, fruity odor that is a good warning property. Vapor pressure is 173 mm Hg at 20°C (68°F). Flammable.
Methyl acetylene (propyne [CAS: 74-99-7]): A CNS depressant and respiratory irritant at very high air concentrations in test animals.	1000 ppm	1700 ppm [LEL]	2 4 2	Colorless gas with sweet odor. Flammable.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Methyl acrylate (2-propenoic acid methyl ester [CAS: 96-33-3]): Highly irritating upon direct contact; severe burns may result. A possible skin sensitizer. Vapors highly irritating to the eyes and respiratory tract. Based on structural analogies, compounds containing the acrylate moiety may be carcinogens.	2 ppm, S, SEN	250 ppm	3 3 2	Colorless liquid with a sharp, fruity odor. Vapor pressure is 68.2 mm Hg at 20°C (68°F). Inhibitor included to prevent violent polymerization.
Methylal (dimethoxymethane [CAS: 109-87-5]): Mildly irritating to eyes and respiratory tract. A CNS depressant at very high levels. Animal studies suggest a potential to injure heart, liver, kidneys, and lungs at very high air levels.	1000 ppm	2200 ppm [LEL]	2 3 2	Colorless liquid with pungent, chloroform-like odor. Highly flammable.
Methylacrylonitrile (2-methyl-2-pro-penenitrile, methacrylonitrile [CAS: 126-98-7]): Mildly irritating upon direct contact. Well absorbed dermally. Metabolized to cyanide (see p 177). In animal tests, acute inhalation at high levels caused death without signs of irritation, probably by a mechanism similar to that of acrylonitrile. Lower levels produced convulsions and loss of motor control in hind limbs.	1 ppm, S			Liquid. Vapor pressure is 40 mm Hg at 13°C (55°F).
Methyl alcohol (methanol, wood alcohol [CAS: 67-56-1]): Mildly irritating to eyes and skin. Systemic toxicity may result from absorption by all routes. Toxic metabolites are formate and formaldehyde. A CNS depressant. Signs and symptoms include headache, nausea, abdominal pain, dizziness, shortness of breath, metabolic acidosis, and coma. Visual disturbances (optic neuropathy) range from blurred vision to blindness. See also p 260.	200 ppm, S	6000 ppm ERPG-1: 200 ppm ERPG-2: 1000 ppm ERPG-3: 5000 ppm	1 3 0	Colorless liquid with a distinctive, sharp odor that is a poor warning property. Flammable. Found in windshield fluids and antifreezes.
Methylamine (CAS: 74-89-5): Corrosive. Vapors highly irritating to eyes, skin, and respiratory tract; severe burns and pulmonary edema may result.	5 ppm	100 ppm ERPG-1: 10 ppm ERPG-2: 100 ppm ERPG-3: 500 ppm	3 4 0	Colorless gas with a fishy or ammonia-like odor. Odor is a poor warning property owing to olfactory fatigue. Flammable.
Methyl-<i>n</i>-amyl ketone (2-heptanone [CAS: 110-43-0]): Vapors are irritating to eyes and respiratory tract. A CNS depressant.	50 ppm	800 ppm	1 2 0	Colorless or white liquid with a fruity odor. Vapor pressure is 2.6 mm Hg at 20°C (68°F).

***N*-methylaniline (CAS: 100-61-8):** A potent inducer of methemoglobinemia (see p 261). Well absorbed by all routes. Animal studies suggest potential for liver and kidney injury.

0.5 ppm,
S

Yellow to light brown liquid with a weak ammonia-like odor. Vapor pressure is less than 1 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of nitrogen.

Methyl bromide (bromomethane [CAS: 74-83-9]): Causes severe irritation and burns upon direct contact. Vapors irritating to the lung; pulmonary edema may result. The CNS, liver, and kidneys are major target organs; acute poisoning causes nausea, vomiting, delirium, and convulsions. Both inhalation and skin exposure may cause systemic toxicity. Chronic exposures associated with peripheral neuropathy in humans. Evidence for adverse effects on fetal development in test animals. Limited evidence of carcinogenicity in test animals (IARC 3). See also p 263, and chloropicrin in this table.

1 ppm,
S
NIOSH CA

250 ppm
ERPG-2: 50 ppm
ERPG-3: 200 ppm

3 1 0

Colorless liquid or gas with a mild chloroform-like odor that is a poor warning property. Chloropicrin, a lacrimator, is often added as a warning agent. Methyl bromide is a widely used fumigant in agriculture and in structural pesticide control.

Methyl *n*-butyl ketone (MBK, 2-hexanone [CAS: 591-78-6]): Vapors irritating to eyes and respiratory tract at high levels. A CNS depressant at high doses. Causes peripheral neuropathy by a mechanism thought to be the same as that of *n*-hexane. Well absorbed by all routes. Causes testicular toxicity in animal studies.

5 ppm,
S

1600 ppm

2 3 0

Colorless liquid with an acetone-like odor. Vapor pressure is 3.8 mm Hg at 20°C (68°F). Flammable. NIOSH recommended exposure limit is 1.0 ppm.

Methyl chloride (CAS: 74-87-3): Once used as an anesthetic. Symptoms include headache, confusion, ataxia, convulsions, and coma. Liver, kidney, and bone marrow are other target organs. Evidence for adverse effects on both the testes and fetal development in test animals at high doses.

50 ppm,
S
NIOSH CA

2000 ppm
ERPG-2: 400 ppm
ERPG-3: 1000 ppm

1 4 0

Colorless gas with a mild, sweet odor that is a poor warning property. Highly flammable.

Methyl-2-cyanoacrylate (CAS: 137-05-3): Vapors irritating to the eyes and upper respiratory tract. May act as a sensitizer. A strong and fast-acting glue that can fasten body parts to each other or surfaces. Direct contact with the eye may result in mechanical injury if the immediate bonding of the eyelids is followed by forced separation.

0.2 ppm

Colorless viscous liquid. Commonly, this compound and related ones are known as “super glues.”

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Methylcyclohexane (CAS: 108-87-2): Irritating upon direct contact. Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels. Based on animal studies, some liver and kidney injury may occur at chronic high doses.	400 ppm	1200 ppm [LEL]	2 3 0	Colorless liquid with a faint benzene-like odor. Vapor pressure is 37 mm Hg at 20°C (68°F). Highly flammable.
<i>o</i>-Methylcyclohexanone (CAS: 583-60-8): Based on animal studies, irritating upon direct contact. Dermal absorption occurs. Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels.	50 ppm, S	600 ppm	– 2 0	Colorless liquid with mild peppermint odor. Irritation is a good warning property. Vapor pressure is about 1 mm Hg at 20°C (68°F). Flammable.
Methyl demeton (<i>O,O</i>-dimethyl 2-ethylmercaptoethyl thiophosphate [CAS: 8022-00-2]): An organophosphate-type cholinesterase inhibitor (see p 291).	0.5 mg/m ³ , S			Colorless to pale yellow liquid with an unpleasant odor. Vapor pressure is 0.00036 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of sulfur and phosphorus.
4,4'-Methylene-bis(2-chloroaniline) (MOCA [CAS: 101-14-4]): A carcinogen in test animals (IARC 2A). Dermal absorption occurs.	0.01 ppm, S, A2 NIOSH CA			Tan solid. Thermal-breakdown products include oxides of nitrogen and hydrogen chloride.
Methylene bis(4-cyclohexylisocyanate) (CAS: 5124-30-1): A strong irritant and skin sensitizer. Based on analogy to other isocyanates, vapors are likely to be potent respiratory tract irritants and sensitizers. See also p 232.	0.005 ppm			White to pale yellow solid flakes. Odorless. Possible thermal-breakdown products include oxides of nitrogen and hydrogen cyanide.
Methylene bisphenyl isocyanate (4,4-di-phenylmethane diisocyanate, MDI [CAS: 101-68-8]): Irritating upon direct contact. Vapors and dusts highly irritating to eyes and respiratory tract. Potent respiratory tract sensitizer (asthma). See also p 232.	0.005 ppm	75 mg/m ³ ERPG-1: 0.2 ppm ERPG-2: 2 ppm ERPG-3: 25 ppm		White to pale yellow flakes. Odorless. Vapor pressure is 0.05 mm Hg at 20°C (68°F). Possible thermal-breakdown products include oxides of nitrogen and hydrogen cyanide. Component of urethanes.

Methylene chloride (methylene dichloride, dichloromethane [CAS: 75-09-2]): Irritating upon prolonged direct contact. Dermal absorption occurs. Vapors irritating to eyes and respiratory tract. A CNS depressant. May cause cardiac arrhythmias. Liver and kidney injury at high concentrations. Converted to carbon monoxide in the body with resultant carboxyhemoglobin formation. A carcinogen in test animals (IARC 2B). See also p 265.	50 ppm, A3 OSHA CA NIOSH CA	2300 ppm ERPG-1: 200 ppm ERPG-2: 750 ppm ERPG-3: 4000 ppm	2 1 0	Heavy colorless liquid with a chloroform-like odor that is a poor warning property. Vapor pressure is 350 mm Hg at 20°C (68°F). Possible thermal-breakdown products include phosgene and hydrogen chloride. Methylene chloride is a solvent with many industrial and commercial uses (eg, furniture strippers, carburetor cleaners).
4,4'-Methylene dianiline (4,4'-diaminodiphenylmethane [CAS: 101-77-9]): Vapors highly irritating to eyes and respiratory tract. Hepatotoxicity (cholestatic jaundice) observed in overexposed workers. Systemic toxicity may result from inhalation, ingestion, or skin contact. Methemoglobinemia (see p 261), kidney injury, retinal injury, and evidence of carcinogenicity in animals (IARC 2B).	0.1 ppm, S, A3 NIOSH CA		3 1 0	Light brown solid crystals with a faint amine odor. Combustible. Thermal-breakdown products include oxides of nitrogen.
Methyl ethyl ketone (2-butanone, MEK [CAS: 78-93-3]): Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels. Limited evidence for adverse effects on fetal development in test animals. Potentiates neurotoxicity of methyl butyl ketone and <i>n</i> -hexane.	200 ppm	3000 ppm	1 3 0	Colorless liquid with a mild acetone odor. Vapor pressure is 77 mm Hg at 20°C (68°F). Flammable.
Methyl ethyl ketone peroxide (CAS: 1338-23-4): Based on chemical reactivity, highly irritating upon direct contact; severe burns may result. Vapors or mists likely to be highly irritating to the eyes and respiratory tract. In animal tests, overexposure resulted in liver, kidney, and lung damage.	0.2 ppm (C)			Colorless liquid with a characteristic odor. Shock sensitive. Breaks down above 50°C (122°F). Explodes upon rapid heating. May contain additives such as dimethyl phthalate, cyclohexanone peroxide, or diallylphthalate to add stability.
Methyl formate (CAS: 107-31-3): Vapors highly irritating to eyes and respiratory tract. A CNS depressant at high levels. Exposure has been associated with visual disturbances, including temporary blindness.	100 ppm	4500 ppm	2 4 0	Colorless liquid with a pleasant odor at high levels. Odor is a poor warning property. Vapor pressure is 476 mm Hg at 20°C (68°F). Highly flammable.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <— 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Methylhydrazine (monomethylhydrazine [CAS: 60-34-4]): Similar to hydrazine in toxic actions. Vapors likely to be highly irritating to the eyes and respiratory tract. Causes methemoglobinemia (see p 261). Potent hemolysin. Highly hepatotoxic. Causes kidney injury. A convulsant. A carcinogen in test animals.	0.01 ppm, S, A3 NIOSH CA	20 ppm	4 3 2	Colorless clear liquid. Vapor pressure is 36 mm Hg at 20°C (68°F). Flammable. In addition to potential industrial uses, exposure to methylhydrazine can occur from ingestion of false morel mushrooms.
Methyl iodide: (iodomethane [CAS: 74-88-4]): An alkylating agent. Based on chemical properties, likely to be highly irritating upon direct contact; severe burns may result. Dermal absorption is likely. Vapors highly irritating to respiratory tract; pulmonary edema has resulted. Neurotoxic; signs and symptoms include nausea, vomiting, dizziness, slurred speech, visual disturbances, ataxia, tremor, irritability, convulsions, and coma. Delusions and hallucinations may last for weeks during recovery. Severe hepatic injury may also occur. Limited evidence of carcinogenicity in test animals (IARC 3).	2 ppm, S, NIOSH CA	100 ppm ERPG-1: 25 ppm ERPG-2: 50 ppm ERPG-3: 125 ppm		Colorless, yellow, red, or brown liquid. Not combustible. Vapor pressure is 375 mm Hg at 20°C (68°F). Thermal-breakdown products include iodine and hydrogen iodide.
Methyl isoamyl ketone (5-methyl-2-hexanone [CAS: 110-12-3]): By analogy to other aliphatic-ketones, vapors are likely to be irritating to eyes and respiratory tract. Likely to be a CNS depressant.	50 ppm		1 2 0	Colorless liquid with a pleasant odor. Vapor pressure is 4.5 mm Hg at 20°C (68°F). Flammable.
Methyl isobutyl ketone (4-methyl-2-pentanone, hexone [CAS: 108-10-1]): Irritating to eyes upon direct contact. Vapors irritating to eyes and respiratory tract. Reported systemic symptoms in humans are weakness, dizziness, ataxia, nausea, vomiting, and headache. High-dose studies in animals suggest a potential for liver and kidney injury.	50 ppm	500 ppm	2 3 1	Colorless liquid with a mild odor. Vapor pressure is 7.5 mm Hg at 25°C (77°F). Flammable.

Methyl isocyanate (MIC [CAS: 624-83-9]): Highly reactive; highly corrosive upon direct contact. Vapors extremely irritating to eyes, skin, and respiratory tract; severe burns and pulmonary edema have resulted. A sensitizing agent. Toxicity is not related to cyanide. Evidence that severe poisonings have adverse effects on fetal development. See also p 232.	0.02 ppm, S	3 ppm ERPG-1: 0.025 ppm ERPG-2: 0.5 ppm ERPG-3: 5 ppm	4 3 2 W	Colorless liquid with a sharp, disagreeable odor that is a poor warning property. Vapor pressure is 348 mm Hg at 20°C (68°F). Flammable. Reacts with water to release methylamine. Polymerizes upon heating. Thermal-breakdown products include hydrogen cyanide and oxides of nitrogen. Used as a chemical intermediate in pesticide synthesis. MIC is not in urethanes.
Methyl mercaptan (CAS: 74-93-1): Causes delayed-onset pulmonary edema. CNS effects include narcosis and convulsions. Reported to have caused methemoglobinemia and hemolysis in a patient with G6PD deficiency (see p 261).	0.5 ppm	150 ppm ERPG-1: 0.005 ppm ERPG-2: 25 ppm ERPG-3: 100 ppm	4 4 0	Colorless liquid with an offensive rotten egg odor. Odor and irritation are good warning properties.
Methyl methacrylate (CAS: 80-62-6): Irritating upon direct contact. Vapors irritating to the eyes, skin, and respiratory tract. A sensitizer (asthma). At very high levels may produce headache, nausea, vomiting, dizziness. Limited evidence for adverse effects on fetal development in animal tests at very high doses.	50 ppm, SEN	1000 ppm	2 3 2	Colorless liquid with a pungent, acrid, fruity odor. Vapor pressure is 35 mm Hg at 20°C (68°F). Flammable. Contains inhibitors to prevent self-polymerization. Used in resin polymers, including medical applications.
Methyl parathion (O,O-dimethyl O-p-nitro-phenylphosphorothioate [CAS: 298-00-0]): A highly potent organophosphate cholinesterase inhibitor (see p 291).	0.2 mg/m ³ , S			Tan liquid with a strong garlic-like odor. Vapor pressure is 0.5 mm Hg at 20°C (68°F). Appearance may vary with formulation.
Methyl propyl ketone (2-pentanone [CAS: 107-87-9]): Vapors irritating to eyes and respiratory tract. Based on animal studies, a CNS depressant at high levels.	200 ppm	1500 ppm	2 3 0	Colorless liquid with a characteristic odor. Vapor pressure is 27 mm Hg at 20°C (68°F). Flammable.
Methyl silicate (tetramethoxy silane [CAS: 681-84-5]): Highly reactive; corrosive upon direct contact; severe burns and loss of vision may result. Vapors extremely irritating to eyes and respiratory tract; severe eye burns and pulmonary edema may result.	1 ppm	ERPG-2: 10 ppm ERPG-3: 20 ppm		Colorless crystals. Reacts with water, forming silicic acid and methanol.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
α-Methylstyrene (CAS: 98-83-9): Slightly irritating upon direct contact. Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels.	50 ppm	700 ppm	1 2 1	Colorless liquid with a characteristic odor. Irritation is an adequate warning property. Vapor pressure is 1.9 mm Hg at 20°C (68°F). Flammable.
Methyl tert butyl ether (MTBE [CAS: 1634-04-4]): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant; acute exposure at high levels can cause nausea, vomiting, dizziness, and sleepiness. Adverse effects on liver and kidney in test animals at high levels. Evidence for adverse effects on reproduction and carcinogenicity in test animals exposed to very high concentrations.				A volatile colorless liquid at room temperature. Gasoline additive. Vapor pressure is 248 mm Hg at 25°C.
Metribuzin (4-amino-6-[1,1-dimethylethyl]-3-[methylthio]-1,2,4-triazin-5 [4H]-one [CAS: 21087-64-9]): Human data available reveal no irritation or sensitization after dermal exposure. In animal testing, was poorly absorbed through the skin and produced no direct skin or eye irritation. Repeated high doses caused CNS depression and liver and thyroid effects.	5 mg/m ³			Vapor pressure is 0.00001 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of sulfur and nitrogen.
Mevinphos (2-carbomethoxy-1-methylvinyl dimethyl phosphate, phosdrin [CAS: 7786-34-7]): An organophosphate cholinesterase inhibitor (see p 291). Well absorbed by all routes. Repeated exposures to low levels can accumulate to produce symptoms.	0.09 mg/m ³ , S	4 ppm		Colorless or yellow liquid with a faint odor. Vapor pressure is 0.0022 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include phosphoric acid mist.
Mica (CAS: 12001-25-2): Dusts may cause pneumoconiosis upon chronic inhalation.	3 mg/m ³ (respirable dust)	1500 mg/m ³		Colorless solid flakes or sheets. Odorless. Vapor pressure is negligible at 20°C (68°F). Noncombustible.

Monocrotophos (dimethyl 2-methylcarbamoyl-1-methylvinyl phosphate [CAS: 6923-22-4]): An organophosphate-type cholinesterase inhibitor (see p 291). Limited human data indicate it is well absorbed through the skin but is rapidly metabolized and excreted.	0.05 mg/m ³ , S				Reddish-brown solid with a mild odor.	
Morpholine (tetrahydro-1,4-oxazine [CAS: 110-91-8]): Corrosive; extremely irritating upon direct contact; severe burns may result. Well absorbed dermally. Vapors irritating to eyes and respiratory tract. Exposure to vapors has caused transient corneal edema. May cause severe liver and kidney injury.	20 ppm, S	1400 ppm [LEL]	3	3	0	Colorless liquid with mild ammonia-like odor. Vapor pressure is 7 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include oxides of nitrogen. Found in some consumer polish and wax products.
Naphthalene (CAS: 91-20-3): Highly irritating to eyes upon direct contact. Vapors are irritating to eyes and may cause cataracts upon chronic exposure. Dermally well absorbed. May induce methemoglobinemia (see p 261). Symptoms of overexposure include headache and nausea. See also p 275.	10 ppm	250 ppm	2	2	0	White to brown solid. The mothball odor and respiratory tract irritation are good warning properties. Current mothball formulations in the US do not contain naphthalene. Vapor pressure is 0.05 mm Hg at 20°C (68°F). Combustible.
β-Naphthylamine (2-aminonaphthalene [CAS: 91-59-8]): Acute overexposures can cause methemoglobinemia (see p 261) or acute hemorrhagic cystitis. Well absorbed through skin. Known human bladder carcinogen.	A1 OSHA CA NIOSH CA					White to reddish crystals. Vapor pressure is 1 mm Hg at 108°C (226°F). Combustible.
Nickel carbonyl (nickel tetracarbonyl [CAS: 13463-39-3]): Inhalation of vapors can cause severe lung and systemic injury without irritant warning signs. Symptoms include headache, nausea, vomiting, fever, and extreme weakness. Based on animal studies, liver and brain damage may occur. Adverse effects on fetal development in test animals. A carcinogen in test animals.	0.05 ppm (as Ni) NIOSH CA	2 ppm (as Ni)	4	3	3	Colorless liquid or gas. The musty odor is a poor warning property. Vapor pressure is 321 mm Hg at 20°C (68°F). Highly flammable. Exposures largely limited to nickel refining.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Nickel metal and soluble inorganic salts (nickel chloride, nickel sulfate, nickel nitrate, nickel oxide): May cause a severe sensitization dermatitis, "nickel itch," upon repeated contact. Fumes highly irritating to the respiratory tract. Some compounds have adverse effects on fetal development in test animals. Some compounds are human nasal and lung carcinogens (IARC 1).	1.5 mg/m ³ (elemental) 0.1 mg/m ³ (soluble compounds), as Ni 0.2 mg/m ³ , A1 (insoluble compounds), as Ni	10 mg/m ³ (as Ni)		Gray metallic powder or green solids. All forms are odorless.
Nicotine (CAS: 54-11-5): A potent nicotinic cholinergic receptor agonist. Well absorbed by all routes of exposure. Symptoms include dizziness, confusion, weakness, nausea and vomiting, tachycardia and hypertension, tremors, convulsions, and muscle paralysis. Death from respiratory paralysis can be very rapid. Adverse effects on fetal development in animal studies. See also p 277.	0.5 mg/m ³ , S	5 mg/m ³	4 1 0	Pale yellow to dark brown viscous liquid with a fishy or amine-like odor. Vapor pressure is 0.0425 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include oxides of nitrogen. Although generally thought of in context of tobacco use and abstinence products, nicotine is a widely used pesticide.
Nitric acid (aqua fortis, engraver's acid [CAS: 7697-37-2]): Concentrated solutions corrosive to eyes and skin; very severe penetrating burns result. Vapors highly irritating to eyes and respiratory tract; pulmonary edema has resulted. Chronic inhalation exposure can produce bronchitis and erosion of the teeth.	2 ppm	25 ppm ERPG-1: 1 ppm ERPG-2: 6 ppm ERPG-3: 78 ppm	3 0 0 Ox (≤ 40%) 4 0 1 Ox (fuming)	Colorless, yellow, or red fuming liquid with an acrid, suffocating odor. Vapor pressure is approximately 62 mm Hg at 25°C (77°F). Not combustible.
Nitric oxide (NO, nitrogen monoxide [CAS: 10102-43-9]): Nitric oxide slowly converts to nitrogen dioxide in air; eye and mucous membrane irritation and pulmonary edema are likely from nitrogen dioxide. Overexposures have been reported to result in acute and chronic obstructive airway disease. Based on animal studies, may cause methemoglobinemia (see p 261). Binds to hemoglobin at the same site as oxygen and this may contribute to the toxicity. See also p 280.	25 ppm	100 ppm		Colorless or brown gas. The sharp, sweet odor occurs below the TLV and is a good warning property.

p-Nitroaniline (CAS: 100-01-6): Irritating to eyes upon direct contact; may injure cornea. Well absorbed by all routes. Overexposure results in headache, weakness, respiratory distress, and methemoglobinemia (see p 261). Liver damage may also occur.	3 mg/m ³ , S	300 mg/m ³	3 1 2	Yellow solid with an ammonia-like odor that is a poor warning property. Vapor pressure is much less than 1 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include oxides of nitrogen.
Nitrobenzene (CAS: 98-95-3): Irritating upon direct contact; sensitization dermatitis may occur. Well absorbed by all routes. Causes methemoglobinemia (see p 261). Symptoms include headache, cyanosis, weakness, and gastrointestinal upset. May injure liver. Injures testes in animals. Limited evidence for adverse effects on fetal development in animals.	1 ppm, S, A3	200 ppm	3 2 1	Pale yellow to dark brown viscous liquid. Shoe polish-like odor is a good warning property. Vapor pressure is much less than 1 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include oxides of nitrogen.
p-Nitrochlorobenzene (CAS: 100-00-5): Irritating upon direct contact; sensitization dermatitis may occur upon repeated exposures. Well absorbed by all routes. Causes methemoglobinemia (see p 261). Symptoms include headache, cyanosis, weakness, and gastrointestinal upset. May cause liver and kidney injury.	0.1 ppm, S, A3	100 mg/m ³	3 1 1	Yellow solid with a sweet odor. Vapor pressure is 0.009 mm Hg at 25°C (77°F). Combustible. Thermal-breakdown products include oxides of nitrogen and hydrogen chloride.
4-Nitrodiphenyl (4-nitrobiphenyl [CAS: 92-93-3]): Extremely well absorbed through skin. Produces bladder cancer in dogs and rabbits. Metabolized to 4-aminodiphenyl which is a potent carcinogen in humans.	S, A2 OSHA CA NIOSH CA			White solid with a sweet odor. Thermal-breakdown products include oxides of nitrogen.
Nitroethane (CAS: 79-24-3): Based on high-exposure studies in animals, vapors are irritating to the respiratory tract. A CNS depressant. Can cause methemoglobinemia (see p 261). Causes liver injury at high levels of exposure in test animals. A structurally similar compound, 2-nitropropane, is a carcinogen.	100 ppm	1000 ppm	1 3 3 (explodes on heating)	Colorless viscous liquid with a fruity odor that is a poor warning property. Vapor pressure is 15.6 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include oxides of nitrogen.
Nitrogen dioxide (CAS: 10102-44-0): Gases and vapors irritating to eyes and respiratory tract; fatal pulmonary edema has resulted. Initial symptoms include cough and dyspnea. Pulmonary edema may appear after a delay of several hours. The acute phase may be followed by a fatal secondary stage, with fever and chills, dyspnea, cyanosis, and delayed-onset pulmonary edema. See p 280.	3 ppm	20 ppm	3 0 0 Ox	Dark brown fuming liquid or gas. Pungent odor and irritation occur only slightly above the TLV and are adequate warning properties. Vapor pressure is 720 mm Hg at 20°C (68°F). Important exposures include structural fires, silage (silo-filling), and gas-shielded (MIG or TIG) welding.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Nitrogen trifluoride (nitrogen fluoride [CAS: 7783-54-2]): Vapors may cause eye irritation. Based on animal studies, may cause methemoglobinemia (see p 261) and liver and kidney damage.	10 ppm	1000 ppm		Colorless gas with a moldy odor that is a poor warning property. Not combustible. Highly reactive and explosive under a number of conditions.
Nitroglycerin (glycerol trinitrate [CAS: 55-63-0]): Causes vasodilation, including coronary arteries. Headache and drop in blood pressure are common. Well absorbed by all routes. Tolerance to vasodilation can occur; cessation of exposure may precipitate angina pectoris in pharmacologically dependent workers. See also p 279.	0.05 ppm, S	75 mg/m ³	2 2 4	Pale yellow viscous liquid. Vapor pressure is 0.00026 mm Hg at 20°C (68°F). Highly explosive.
Nitromethane (CAS: 75-52-5): Based on high-dose animal studies, causes respiratory tract irritation, liver and kidney injury, and CNS depression with ataxia, weakness, convulsions, and, possibly, methemoglobinemia (see p 261).	20 ppm, A3	750 ppm	1 3 4	Colorless liquid with a faint fruity odor that is a poor warning property. Vapor pressure is 27.8 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of nitrogen.
1-Nitropropane (CAS: 108-03-2): Vapors mildly irritating to eyes and respiratory tract. Liver and kidney injury may occur.	25 ppm	1000 ppm	1 3 2 (may explode on heating)	Colorless liquid with a faint fruity odor that is a poor warning property. Vapor pressure is 7.5 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include oxides of nitrogen.
2-Nitropropane (CAS: 79-46-9): Mildly irritating; CNS depressant at high exposures. Highly hepatotoxic; fatalities have resulted. Renal toxicity also occurs. Well absorbed by all routes. Limited evidence for adverse effects on fetal development in test animals. A carcinogen in test animals (IARC 2B).	10 ppm, A3 NIOSH CA	100 ppm	1 3 2 (may explode on heating)	Colorless liquid. Vapor pressure is 12.9 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include oxides of nitrogen.
N-Nitrosodimethylamine (dimethylnitrosamine [CAS: 62-75-9]): Overexposed workers suffered severe liver damage. Based on animal studies, well absorbed by all routes. A potent animal carcinogen producing liver, kidney, and lung cancers (IARC 2A).	A3, S OSHA CA NIOSH CA			Yellow viscous liquid. Combustible.

Nitrotoluene (<i>o</i>-, <i>m</i>-, <i>p</i>-nitrotoluene [CAS: 99-08-1]): Weak inducer of methemoglobinemia (see p 261). By analogy to structurally similar compounds, dermal absorption is likely.	2 ppm, S	200 ppm	3 1 1	<i>Ortho</i> and <i>meta</i> , yellow liquid or solid. <i>Para</i> , yellow solid. All isomers have a weak, aromatic odor. Vapor pressure is approximately 0.15 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of nitrogen. Intermediate in synthesis of dye-stuffs and explosives.
Nitrous oxide (CAS: 10024-97-2): A CNS depressant. Hematopoietic effects from chronic exposure include megaloblastic anemia. Substance abuse has resulted in neuropathies. May have an adverse effect on human fertility and fetal development. See also p 282.	50 ppm			Colorless gas. Sweet odor. Not combustible. Widely used as an anesthetic gas in dentistry, and a popular drug of abuse.
Octachloronaphthalene (Halowax 1051 [CAS: 2234-13-1]): By analogy to other chlorinated naphthalenes, workers overexposed by inhalation or skin contact may experience chloracne and liver damage.	0.1 mg/m ³ , S			Pale yellow solid with an aromatic odor. Vapor pressure is less than 1 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen chloride.
Octane (CAS: 111-65-9): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant at very high concentrations.	300 ppm	1000 ppm [LEL]	0 3 0	Colorless liquid. Gasoline-like odor and irritation are good warning properties. Vapor pressure is 11 mm Hg at 20°C (68°F). Flammable.
Osmium tetroxide (osmic acid [CAS: 20816-12-0]): Corrosive upon direct contact; severe burns may result. Fumes are highly irritating to eyes and respiratory tract. Based on high-dose animal studies, bone marrow injury and kidney damage may occur.	0.0002 ppm (as Os)	1 mg/m ³ (as Os)		Colorless to pale yellow solid with a sharp and irritating odor like chlorine. Vapor pressure is 7 mm Hg at 20°C (68°F). Not combustible. Catalyst and laboratory reagent.
Oxalic acid (ethanedioic acid [CAS: 144-62-7]): A strong acid; corrosive to eyes and to skin upon direct contact (see p 157). Fumes irritating to respiratory tract. Highly toxic upon ingestion; precipitation of calcium oxalate crystals can cause hypocalcemia and renal damage. See also p 295.	1 mg/m ³	500 mg/m ³	3 1 0	Colorless or white solid. Odorless. Vapor pressure is less than 0.001 mm Hg at 20°C (68°F).

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Oxygen difluoride (oxygen fluoride, fluorine monoxide [CAS: 7783-41-7]): Extremely irritating to the eyes, skin, and respiratory tract. Effects similar to hydrofluoric acid (see p 221.) Based on animal studies, may also injure kidney, internal genitalia, and other organs. Workers have complained of severe headaches after low-level exposures.	0.05 ppm (C)	0.5 ppm		Colorless gas with a strong and foul odor. Olfactory fatigue is common, so odor is a poor warning property. A strong oxidizing agent.
Ozone (triatomic oxygen [CAS: 10028-15-6]): Irritating to eyes and respiratory tract. Pulmonary edema has been reported. See also p 213.	0.05 ppm (heavy work); 0.08 ppm (moderate work); 0.1 ppm (light work); 0.2 ppm (≤ 2 hours)	5 ppm		Colorless or bluish gas. Sharp, distinctive odor is an adequate warning property. A strong oxidizing agent. Gas-shielded and specialty welding are potential sources of exposure, in addition to water purification and industrial bleaching operations.
Paraquat (1,1'-dimethyl-4,4'-bipyridinium dichloride [CAS: 4687-14-7]): Extremely irritating upon direct contact; severe corrosive burns may result. Well absorbed through skin. A potent toxin causing acute multiorgan failure as well as progressive fatal pulmonary fibrosis after ingestion. See also p 296.	0.5 mg/m ³	1 mg/m ³		Odorless white to yellow solid. Vapor pressure is negligible at 20°C (68°F). Not combustible. Thermal-breakdown products include oxides of nitrogen and sulfur and hydrogen chloride. While widely used as a herbicide, most deaths occur as a result of ingestion.
Parathion (O,O-diethyl O-p-nitrophenyl phosphorothioate [CAS: 56-38-2]): Highly potent organophosphate cholinesterase inhibitor (see p 291). Systemic toxicity has resulted from inhalation, ingestion, and dermal exposures. Evidence for adverse effects on fetal development in test animals at high doses.	0.1 mg/m ³ , S	10 mg/m ³		Yellow to dark brown liquid with garlic-like odor. Odor threshold of 0.04 ppm suggests it has good warning properties. Vapor pressure is 0.0004 mm Hg at 20°C (68°F). Thermal-breakdown products include oxides of sulfur, nitrogen, and phosphorus. In the field, weathering/oxidation can convert parathion to the even more toxic organophosphate, paraoxon.

Pentaborane [CAS: 19624-22-7]: Highly irritating upon direct contact; severe burns may result. Vapors irritating to the respiratory tract. A potent CNS toxin; symptoms include headache, nausea, weakness, confusion, hyperexcitability, tremors, seizures, and coma. CNS effects may persist. Liver and kidney injury may also occur.	0.005 ppm	1 ppm	4 4 2	Colorless liquid. Vapor pressure is 171 mm Hg at 20°C (68°F). The pungent sour-milk odor occurring only at air levels well above the TLV is a poor warning property. May ignite spontaneously. Reacts violently with halogenated extinguishing media. Thermal-breakdown products include boron acids.
Pentachloronaphthalene (Halowax 1013 [CAS: 1321-64-8]): Chloracne results from prolonged skin contact or inhalation. May cause severe, potentially fatal liver injury or necrosis by all routes of exposure.	0.5 mg/m ³ , S			Pale yellow waxy solid with a pleasant aromatic odor. Odor threshold not known. Vapor pressure is less than 1 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen chloride fumes.
Pentachlorophenol (Penta, PCP [CAS: 87-86-5]): Irritating upon direct contact; burns may result. Vapors irritating to eyes and respiratory tract. A potent metabolic poison; uncouples oxidative phosphorylation. Well absorbed by all routes. Evidence for adverse effects on fetal development and carcinogenicity in test animals (IARC 2B). See also p 298.	0.5 mg/m ³ , S, A3	2.5 mg/m ³	3 0 0	Eye and nose irritation occur slightly above the TLV and are good warning properties. Vapor pressure is 0.0002 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen chloride, chlorinated phenols, and octachlorodibenzodioxin. Widely used as a wood preservative.
Pentane (<i>n</i>-pentane [CAS: 109-66-0]): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant at high levels.	600 ppm	1500 ppm [LEL]	1 4 0	Colorless liquid with a gasoline-like odor that is an adequate warning property. Vapor pressure is 426 mm Hg at 20°C (68°F). Flammable.
Petroleum distillates (petroleum naphtha, petroleum ether): Vapors irritating to eyes and respiratory tract. A CNS depressant. If <i>n</i> -hexane, benzene, or other toxic contaminants are present, those hazards should be addressed. See also p 219.		1100 ppm [LEL]	1 4 0 (petroleum ether)	Colorless liquid. Kerosene-like odor at levels below the TLV serves as a warning property. Highly flammable. Vapor pressure is about 40 mm Hg at 20°C (68°F).

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Phenol (carbolic acid, hydroxybenzene [CAS: 108-95-2]): Corrosive acid and protein denaturant. Direct eye or skin contact causes severe tissue damage or blindness. Deep skin burns can occur without warning pain. Systemic toxicity by all routes; percutaneous absorption of vapor occurs. Vapors highly irritating to eyes and respiratory tract. Symptoms include nausea, vomiting, cardiac arrhythmias, circulatory collapse, convulsions, and coma. Toxic to liver and kidney. A tumor promoter. See also p 302.	5 ppm, S	250 ppm ERPG-1: 10 ppm ERPG-2: 50 ppm ERPG-3: 200 ppm	4 2 0	Colorless to pink crystalline solid, or viscous liquid. Its odor has been described as being distinct, acrid, and aromatic or as being sweet and tarry. As the odor is detected at or below the TLV, it is a good warning property. Vapor pressure is 0.36 mm Hg at 20°C (68°F). Combustible.
Phenylenediamine (<i>p</i>-diaminobenzene, <i>p</i>-aminoaniline [CAS: 106-50-3]): Irritating upon direct contact. May cause skin and respiratory tract sensitization (asthma). Inflammatory reactions of larynx and pharynx have often been noted in exposed workers.	0.1 mg/m ³ , A3	25 mg/m ³	– 1 0	White to light purple or brown solid, depending on degree of oxidation. Combustible. Thermal-breakdown products include oxides of nitrogen.
Phenyl ether (diphenyl ether [CAS: 101-84-8]): Mildly irritating upon prolonged direct contact. Vapors irritating to eyes and respiratory tract. Based on high-dose experiments in animals, liver and kidney damage may occur after ingestion.	1 ppm	100 ppm		Colorless liquid or solid. Mildly disagreeable odor detected below the TLV serves as a good warning property. Vapor pressure is 0.02 mm Hg at 25°C (77°F). Combustible.
Phenyl glycidyl ether (PGE, 1,2-epoxy-3-phenoxypropane [CAS: 122-60-1]): Irritating upon direct contact. A skin sensitizer. Based on animal studies, vapors are very irritating to eyes and respiratory tract. In high-dose animal studies, a CNS depressant producing liver, kidney, spleen, testes, thymus, and hematopoietic system injury. A carcinogen in test animals (IARC 2B).	0.1 ppm, S	100 ppm		Colorless liquid with an unpleasant, sweet odor. Vapor pressure is 0.01 mm Hg at 20°C (68°F). Combustible. Readily forms peroxides.
Phenyldiazine (CAS: 100-63-0): A strong base and corrosive upon direct contact. A potent skin sensitizer. Dermal absorption occurs. Vapors very irritating to eyes and respiratory tract. May cause hemolytic anemia with secondary kidney damage. Limited evidence of carcinogenicity in test animals.	0.1 ppm, S, A3 NIOSH CA	15 ppm	3 2 0	Pale yellow crystals or oily liquid with a weakly aromatic odor. Darkens upon exposure to air and light. Vapor pressure is less than 0.1 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include oxides of nitrogen.

Phenylphosphine (CAS: 638-21-1): In animals, subchronic inhalation at 2 ppm caused loss of appetite, diarrhea, tremor, hemolytic anemia, dermatitis, and irreversible testicular degeneration.	0.05 ppm (C)				Crystalline solid. Spontaneously combustible at high air concentrations.
Phorate (O,O-diethyl S-(ethylthio)methyl phosphorodithioate, Thimet, Timet [CAS: 298-02-2]): An organophosphate-type cholinesterase inhibitor (see p 291). Well absorbed by all routes.	0.05 mg/m ³ , S				Clear liquid. Vapor pressure is 0.002 mm Hg at 20°C (68°F).
Phosgene (carbonyl chloride, COCl₂ [CAS: 75-44-5]): Extremely irritating to the lower respiratory tract. Exposure can be insidious because irritation and smell are inadequate as warning properties for pulmonary injury. Higher levels cause irritation of the eyes, skin, and mucous membranes. See also p 305.	0.1 ppm	2 ppm ERPG-2: 0.2 ppm ERPG-3: 1 ppm	4	0 1	Colorless gas. Sweet hay-like odor at low concentrations; sharp and pungent odor at high concentrations. Dangerous concentrations may not be detected by odor.
Phosphine (hydrogen phosphide [CAS: 7803-51-2]): Extremely irritating to the respiratory tract; fatal pulmonary edema has resulted. A multisystem poison. Symptoms in moderately overexposed workers included diarrhea, nausea, vomiting, cough, headache, and dizziness. See also p 306.	0.3 ppm	50 ppm ERPG-2: 0.5 ppm ERPG-3: 5 ppm	4	4 2	Colorless gas. A fishy or garlic-like odor detected well below the TLV is considered to be a good warning property. May ignite spontaneously on contact with air. A common fumigant, generated on-site by aluminum or zinc phosphide and moisture.
Phosphoric acid (CAS: 7664-38-2): A strong corrosive acid; severe burns may result from direct contact. Mist or vapors irritating to eyes and respiratory tract.	1 mg/m ³	1000 mg/m ³	3	0 0	Colorless, syrupy, odorless liquid. Solidifies at temperatures below 20°C (68°F). Vapor pressure is 0.03 mm Hg at 20°C (68°F). Not combustible.
Phosphorus (yellow phosphorus, white phosphorus, P [CAS: 7723-14-0]): Severe, penetrating burns may result upon direct contact. Material may ignite upon contact with skin. Fumes irritating to eyes and respiratory tract; pulmonary edema may occur. Potent hepatotoxin. Systemic symptoms include abdominal pain, jaundice, and garlic odor on the breath. Historically, chronic poisoning caused jaw bone necrosis (phossy jaw). See also p 307.	0.1 mg/m ³ (yellow phosphorus)	5 mg/m ³	4	4 2	White to yellow, waxy or crystalline solid with acrid fumes. Flammable. Vapor pressure is 0.026 mm Hg at 20°C (68°F). Ignites spontaneously on contact with air. Thermal-breakdown products include phosphoric acid fume. Historical exposures involved the match industry, which has long since substituted other forms of phosphorus. Current uses include munitions and pesticides.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Phosphorus oxychloride (CAS: 10025-87-3): Reacts with moisture to release phosphoric and hydrochloric acids; highly corrosive upon direct contact. Fumes extremely irritating to eyes and respiratory tract. Systemic effects include headache, dizziness, and dyspnea. Kidney toxicity may occur.	0.1 ppm		4 0 2 W	Clear colorless to pale yellow, fuming liquid possessing a pungent odor. Vapor pressure is 40 mm Hg at 27.3°C (81°F). Not combustible.
Phosphorus pentachloride (CAS: 10026-13-8): Reacts with moisture to release phosphoric and hydrochloric acids; highly corrosive upon direct contact. Fumes extremely irritating to eyes and respiratory tract.	0.1 ppm	70 mg/m ³	3 0 2 W	Pale yellow solid with a hydrochloric acid-like odor. Not combustible.
Phosphorus pentasulfide (CAS: 1314-80-3): Rapidly reacts with moisture and moist tissues to form hydrogen sulfide (see p 224) and phosphoric acid. Severe burns may result from prolonged contact with tissues. Dusts or fumes extremely irritating to eyes and respiratory tract. Systemic toxicology is predominantly caused by hydrogen sulfide.	1 mg/m ³	250 mg/m ³	2 1 2 W	Greenish-yellow solid with odor of rotten eggs. Olfactory fatigue reduces value of smell as a warning property. Thermal-breakdown products include sulfur dioxide, hydrogen sulfide, phosphorus pentoxide, and phosphoric acid fumes. Ignites spontaneously in the presence of moisture.
Phosphorus trichloride (CAS: 7719-12-2): Reacts with moisture to release phosphoric and hydrochloric acids; highly corrosive upon direct contact. Fumes extremely irritating to eyes and respiratory tract.	0.2 ppm	25 ppm	4 0 2 W	Fuming colorless to yellow liquid. Irritation provides a good warning property. Vapor pressure is 100 mm Hg at 20°C (68°F). Not combustible.
Phthalic anhydride (phthalic acid anhydride [CAS: 85-44-9]): Extremely irritating upon direct contact; chemical burns occur after prolonged contact. Dusts and vapors extremely irritating to respiratory tract. A potent skin and respiratory tract sensitizer (asthma).	1 ppm	60 mg/m ³	3 1 0	White crystalline solid with choking odor at very high air concentrations. Vapor pressure is 0.05 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include phthalic acid fumes.

Picloram (4-amino-3,5,6-trichloropicolinic acid [CAS: 1918-02-1]): Dusts mildly irritating to skin, eyes, and respiratory tract. Has low oral toxicity in test animals. Limited evidence of carcinogenicity in animals.	10 mg/m ³				White powder possessing a bleach-like odor. Vapor pressure is 0.000006 mm Hg at 35°C (95°F). Thermal-breakdown products include oxides of nitrogen and hydrogen chloride.
Picric acid (2,4,6-trinitrophenol [CAS: 88-89-1]): Irritating upon direct contact. Dust stains skin yellow and can cause a sensitization dermatitis. Symptoms of low-level exposure are headache, dizziness, and gastrointestinal upset. May induce methemoglobinemia (see p 261). Ingestion can cause hemolysis, nephritis, and hepatitis. Staining of the conjunctiva and aqueous humor can give vision a yellow hue. A weak uncoupler of oxidative phosphorylation.	0.1 mg/m ³	75 mg/m ³	3	4 4	Pale yellow crystalline solid or paste. Odorless. Vapor pressure is much less than 1 mm Hg at 20°C (68°F). Decomposes explosively above 120°C (248°F). May detonate when shocked. Contact with metals, ammonia, or calcium compounds can form salts that are much more sensitive to shock detonation.
Pindone (Pival, 2-pivaloyl-1,3-indanedione [CAS: 83-26-1]): A vitamin K antagonist anticoagulant (see p 378).	0.1 mg/m ³	100 mg/m ³			Bright yellow crystalline substance.
Piperazine dihydrochloride (CAS: 142-64-3): Irritating upon direct contact; burns may result. A moderate skin and respiratory sensitizer. Nausea, vomiting, and diarrhea are side effects of medicinal use. Overdosage has caused confusion, lethargy, coma, and seizures.	5 mg/m ³				White crystalline solid with a mild fishy odor.
Piperidine (CAS: 110-89-4): Highly irritating upon direct contact; severe burns may result. Vapors irritating to eyes and respiratory tract. Small doses initially stimulate autonomic ganglia; larger doses depress them. A 30–60 mg/kg dose may produce symptoms in humans.			3	3 0	Flammable.
Platinum—soluble salts (sodium chloroplatinate; ammonium chloroplatinate, platinum tetrachloride): Sensitizers causing asthma and dermatitis. Metallic platinum does not share these effects. Soluble platinum compounds are also highly irritating to eyes, mucous membranes, and respiratory tract.	0.002 mg/m ³ (as Pt)	4 mg/m ³ (as Pt)			Appearance varies with the compound. Thermal-breakdown products of some chloride salts include chlorine gas. Used as industrial catalysts and in specialized photographic applications.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Polychlorinated biphenyls (chlorodiphenyls, Aroclor 1242, PCBs): Exposure to high concentrations is irritating to eyes, nose, and throat. Chronically overexposed workers suffer from chloracne and liver injury. Reported symptoms are anorexia, gastrointestinal upset, and peripheral neuropathies. Some health effects may be caused by contaminants or thermal decomposition products. Adverse effects on fetal development and fertility in test animals. A carcinogen in test animals (IARC 2A). See also p 319.	1 mg/m ³ (42% chlorine), S, NIOSH CA 0.5 mg/m ³ (54% chlorine), S, A3 NIOSH CA	5 mg/m ³ (42% or 54% chlorine)	2 1 0	42% chlorinated: a colorless to dark brown liquid with a slight hydrocarbon odor and a vapor pressure of 0.001 mm Hg at 20°C (68°F). 54% chlorinated: light yellow oily liquid with a slight hydrocarbon odor and a vapor pressure of 0.0006 mm Hg at 20°C (68°F). Thermal-breakdown products include chlorinated dibenzofurans and chlorodibenzodioxins. Although no longer used, old transformers may still contain PCBs.
Polytetrafluoroethylene decomposition products: Overexposures result in polymer fume fever, a disease with flu-like symptoms including chills, fever, and cough. See also p 259.				Produced by pyrolysis of Teflon and related materials. Perfluorobutylene and carbonyl fluoride are among the pyrolysis products.
Polyvinyl chloride decomposition products: Fumes are irritating to the respiratory tract and may cause “meat wrapper’s” asthma.				Produced by the high-temperature partial breakdown of polyvinyl chloride plastics.
Portland cement (a mixture of mostly tricalcium silicate and dicalcium silicate with some alumina, calcium aluminate, and iron oxide): Irritant of the eyes, nose, and skin; corrosive burns may occur. Long-term heavy exposure has been associated with dermatitis and bronchitis.	10 mg/m ³ (< 1% quartz)	5000 mg/m ³		Gray powder. Odorless. Portland cement manufacture is typically associated with sulfur dioxide exposure.
Potassium hydroxide (KOH [CAS: 1310-58-3]): A caustic alkali causing severe burns to tissues upon direct contact. Exposure to dust or mist causes eye, nose, and respiratory tract irritation.	2 mg/m ³ (C)		3 0 1	White solid that absorbs moisture. Vapor pressure is negligible at 20°C (68°F). Gives off heat and a corrosive mist when in contact with water.
Propane (CAS: 74-98-6): Simple asphyxiant. See also hydrocarbons, p 219.	2500 ppm	2100 ppm [LEL]	1 4 0	

Propargyl alcohol (2-propyn-1-ol [CAS: 107-19-7]): Irritating to skin upon direct contact. Dermal well absorbed. A CNS depressant. Causes liver and kidney injury in test animals.	1 ppm, S		4 3 3	Light to straw-colored liquid with a geranium-like odor. Vapor pressure is 11.6 mm Hg at 20°C (68°F). Flammable.
Propionic acid (CAS: 79-09-4): Irritating to eyes and skin upon direct contact with concentrated solutions; burns may result. Vapors irritating to eyes, skin, and respiratory tract. A food additive of low systemic toxicity.	10 ppm		3 2 0	Colorless oily liquid with a pungent, somewhat rancid odor. Vapor pressure is 10 mm Hg at 39.7°C (103.5°F). Flammable.
Propoxur (<i>o</i>-isopropoxyphenyl <i>N</i>-methylcarbamate, DDVP, Baygon [CAS: 114-26-1]): A carbamate anticholinesterase insecticide (see p 291). Limited evidence for adverse effects on fetal development in test animals.	0.5 mg/m ³ , A3			White crystalline solid with a faint characteristic odor. Vapor pressure is 0.01 mm Hg at 120°C (248°F). Common insecticide found in many OTC formulations.
<i>n</i>-Propyl acetate (CAS: 109-60-4): Vapors irritating to eyes and respiratory tract. Excessive inhalation may cause weakness, nausea, and chest tightness. Based on high-exposure studies in test animals, a CNS depressant.	200 ppm	1700 ppm	1 3 0	Colorless liquid. Mild fruity odor and irritant properties provide good warning properties. Vapor pressure is 25 mm Hg at 20°C (68°F). Flammable.
Propyl alcohol (1-propanol [CAS: 71-23-8]): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant. See also isopropyl alcohol, p 234.	200 ppm, S	800 ppm	1 3 0	Colorless volatile liquid. Vapor pressure is 15 mm Hg at 20°C (68°F). Mild alcohol-like odor is an adequate warning property.
Propylene dichloride (1,2-dichloropropane [CAS: 78-87-5]): Vapors very irritating to eyes and respiratory tract. Causes CNS depression and severe liver and kidney damage at modest doses in animal studies. Testicular toxicity at high doses in test animals.	75 ppm	400 ppm	2 3 0	Colorless liquid. Chloroform-like odor is considered to be an adequate warning property. Vapor pressure is 40 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include hydrogen chloride. An agricultural nematocide.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Propylene glycol dinitrate (1,2-propylene glycol dinitrate, PGDN [CAS: 6423-43-4]): Mildly irritating upon direct contact. Dermal absorption occurs. May cause methemoglobinemia (see p 261). Causes vasodilation, including coronary arteries. Headache and drop in blood pressure are common. Well absorbed by all routes. Tolerance to vasodilation can occur; cessation of exposure may precipitate angina pectoris in pharmacologically dependent workers. See also nitrates, p 279.	0.05 ppm, S			Colorless liquid with an unpleasant odor. Thermal-breakdown products include oxides of nitrogen.
Propylene glycol monomethyl ether (1-methoxy-2-propanol [CAS: 107-98-2]): Vapors very irritating to the eyes and possibly the respiratory tract. A mild CNS depressant.	100 ppm		0 3 0	Colorless, flammable liquid.
Propylene imine (2-methylaziridine [CAS: 75-55-8]): Very irritating upon direct contact; severe burns may result. Vapors highly irritating to eyes and respiratory tract. May also injure liver and kidneys. Well absorbed dermally. A carcinogen in test animals.	2 ppm, S, A3	100 ppm		A fuming colorless liquid with a strong ammonialike odor. Flammable. Thermal-breakdown products include oxides of nitrogen.
Propylene oxide (2-epoxypropane [CAS: 75-56-9]): Highly irritating upon direct contact; severe burns result. Vapors highly irritating to eyes and respiratory tract. Based on high-dose animal studies, may cause CNS depression and peripheral neuropathy. A carcinogen in test animals (IARC 2A).	2 ppm, SEN, A3	400 ppm ERPG-1: 50 ppm ERPG-2: 250 ppm ERPG-3: 750 ppm	3 4 2	Colorless liquid. Its sweet, ether-like odor is considered to be an adequate warning property. Vapor pressure is 442 mm Hg at 20°C (68°F). Highly flammable. Polymerizes violently.
<i>n</i>-Propyl nitrate (nitric acid <i>n</i>-propyl ester [CAS: 627-13-4]): Vaso-dilator causing headaches and hypotension. Causes methemoglobine-mia (see p 261). See also nitrates, p 279.	25 ppm	500 ppm	2 3 3 Ox (may explode on heating)	Pale yellow liquid with an unpleasant sweet odor. Vapor pressure is 18 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include oxides of nitrogen.

Pyrethrum (pyrethrin I or II; cinerin I or II; jasmolin I or II): Dusts cause primary contact dermatitis and skin and respiratory tract sensitization (asthma). Of very low systemic toxicity. See also p 322.	5 mg/m ³	5000 mg/m ³		Vapor pressure is negligible at 20°C (68°F). Combustible. Widely used insecticide.
Pyridine (CAS: 110-86-1): Irritating upon prolonged direct contact; occasional reports of skin sensitization. Vapors irritating to eyes and respiratory tract. A CNS depressant. Induces methemoglobinemia. Chronic ingestion of small amounts has caused fatal liver and kidney injury. Workers exposed to 6–12 ppm have complained of headache, dizziness, and gastrointestinal upset. Dermally well absorbed.	5 ppm	1000 ppm	3 3 0	Colorless or yellow liquid with a nauseating odor and a definite “taste” that serves as a good warning property. Vapor pressure is 18 mm Hg at 20°C (68°F). Flammable. Thermal-breakdown products include oxides of nitrogen and cyanide.
Pyrogallol (1,2,3-trihydroxybenzene; pyrogalllic acid [CAS: 87-66-1]): Highly irritating upon direct contact; severe burns may result. Potent reducing agent and general cellular poison. Causes methemoglobinemia (see p 261). Attacks heart, lungs, liver, kidneys, red blood cells, bone marrow, and muscle. Causes sensitization dermatitis. Deaths have resulted from the topical application of salves containing pyrogallol.				White to gray odorless solid.
Quinone (1,4-cyclohexadienedione, <i>p</i>-benzoquinone [CAS: 106-51-4]): A severe irritant of the eyes and respiratory tract. May induce methemoglobinemia (see p 261). Acute overexposure to dust or vapors can cause conjunctival irritation and discoloration, corneal edema, ulceration, and scarring. Chronic exposures can permanently reduce visual acuity. Skin contact can cause irritation, ulceration, and pigmentation changes.	0.1 ppm	100 mg/m ³		Pale yellow crystalline solid. The acrid odor is not a reliable warning property. Vapor pressure is 0.1 mm Hg at 20°C (68°F). Sublimes when heated.
Resorcinol (1,3-dihydroxybenzene [CAS: 108-46-3]): Corrosive acid and protein denaturant; extremely irritating upon direct contact; severe burns result. May cause methemoglobinemia (see p 261). A sensitizer. Dermally well absorbed. See also phenol, p 302.	10 ppm		– 1 0	White crystalline solid with a faint odor. May turn pink on contact with air. Vapor pressure is 1 mm Hg at 108°C (226°F). Combustible.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Ronnel (<i>O,O</i>-dimethyl-<i>O</i>-(2,4,5-trichlorophenyl)phosphorothioate, Fenchlorphos [CAS: 299-84-3]): One of the least toxic organophosphate anticholinesterase insecticides (see p 291).	10 mg/m ³	300 mg/m ³		Vapor pressure is 0.0008 mm Hg at 20°C (68°F). Not combustible. Unstable above 149°C (300°F); harmful gases such as sulfur dioxide, dimethyl sulfide, and trichlorophenol may be released.
Rotenone (tubatoxin, cube root, derris root, derrin [CAS: 83-79-4]): Irritating upon direct contact. Dusts irritate the respiratory tract. A metabolic poison; depresses cellular respiration and inhibits mitotic spindle formation. Ingestion of large doses numbs oral mucosa and causes nausea and vomiting, muscle tremors, and convulsions. Chronic exposure caused liver and kidney damage in animal studies. Limited evidence for adverse effects on fetal development in animals at high doses.	5 mg/m ³	2500 mg/m ³		White to red crystalline solid. Vapor pressure is negligible at 20°C (68°F). A natural pesticide extracted from such plants as cube, derris, and timbo. Odorless. Decomposes upon contact with air or light. Unstable to alkali.
Selenium and inorganic compounds (as selenium): Fumes, dusts, and vapors irritating to eyes, skin, and respiratory tract; pulmonary edema may occur. Many compounds are well absorbed dermally. A general cellular poison. Chronic intoxication causes depression, nervousness, dermatitis, gastrointestinal upset, metallic taste in mouth and garlicky odor of breath, excess caries, and loss of fingernails or hair. The liver and kidneys are also target organs. Some selenium compounds have been found to cause birth defects and cancers in test animals. See also p 337.	0.2 mg/m ³ (as Se)	1 mg/m ³ (as Se)		Elemental selenium is a black, gray, or red crystalline or amorphous solid and is odorless.
Selenium dioxide (selenium oxide [CAS: 7446-08-4]): Strong vesicant; severe burns result from direct contact. Converted to selenious acid in the presence of moisture. Well absorbed dermally. Fumes and dusts very irritating to eyes and respiratory tract. See also p 337.				White solid. Reacts with water to form selenious acid.

Selenium hexafluoride (CAS: 7783-79-1): Vesicant. Reacts with moisture to form selenium acids and hydrofluoric acid; severe HF burns may result from direct contact (see p 221). Fumes highly irritating to eyes and respiratory tract; pulmonary edema may result.	0.05 ppm	2 ppm	Colorless gas. Not combustible.
Selenium oxychloride (CAS: 7791-23-3): Strong vesicant. Direct contact can cause severe burns. Dermally well absorbed. Fumes extremely irritating to eyes and respiratory tract; delayed pulmonary edema may result.			Colorless to yellow liquid. Hydrogen chloride and selenious acid fumes produced on contact with moisture.
Silica, amorphous (diatomaceous earth, precipitated and gel silica): Possesses little or no potential to cause silicosis. Most sources of amorphous silica contain quartz (see crystalline silica, below). If greater than 1% quartz is present, the quartz hazard must be addressed. When strongly heated (calcined) with limestone, diatomaceous earth becomes crystalline and can cause silicosis. Amorphous silica has been associated with lung fibrosis, but the role of crystalline silica contamination remains controversial.	10 mg/m ³ (precipitated silica, diatomaceous earth, silica gel) 3 mg/m ³ (respirable dust) 2 mg/m ³ (silica fume)	3000 mg/m ³	White to gray powders. Odorless with a negligible vapor pressure. The TLV for dusts is 10 mg/m ³ if no asbestos and less than 1% quartz are present.
Silica, crystalline (quartz, fused amorphous silica, cristobolite, tridymite, tripoli [CAS: 14464-46-1]): Inhalation of dusts causes silicosis, a progressive, fibrotic scarring of the lung. Individuals with silicosis are much more susceptible to tuberculosis. Some forms of crystalline silica are carcinogenic (IARC 2A).	0.1 mg/m ³ (respirable dust; quartz, fused silica, tripoli) 0.05 mg/m ³ (respirable dust; cristobolite, tridymite)	25 mg/m ³ (cristobolite, tridymite) 50 mg/m ³ (quartz, tripoli)	Colorless, odorless solid with a negligible vapor pressure. A component of many mineral dusts.
Silicon (CAS: 7440-21-3): A nuisance dust that does not cause pulmonary fibrosis. Parenteral exposure has been associated with systemic toxicity.	10 mg/m ³		Gray to black, lustrous needle-like crystals. Vapor pressure is negligible at 20°C (68°F).

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Silicon tetrachloride (tetrachlorosilane [CAS: 10026-04-7]): Generates hydrochloric acid vapor upon contact with moisture; severe burns may result. Extremely irritating to eyes and respiratory tract; pulmonary edema may result.		ERPG-1: 0.75 ppm ERPG-2: 5 ppm ERPG-3: 37 ppm	3 0 2 W	Not combustible.
Silver (CAS: 7440-22-4): Silver compounds cause argyria, a blue-gray discoloration of tissues, which may be generalized throughout the viscera or localized to the conjunctiva, nasal septum, and gums. Some silver salts are corrosive upon direct contact with tissues.	0.01 mg/m ³ (soluble compounds, as Ag) 0.1 mg/m ³ (metal)	10 mg/m ³ (Ag compounds, as Ag)		Compounds vary in appearance. Silver nitrate is a strong oxidizer.
Sodium azide (hydrazoic acid, sodium salt; NaN₃ [CAS: 26628-22-8]): Potent cellular toxin; inhibits cytochrome oxidase. Eye irritation, bronchitis, headache, hypotension, and collapse have been reported in overexposed workers. See also p 122.	0.29 mg/m ³ (C) (as sodium azide) 0.11 ppm (C) (as hydrazoic acid vapor)			White, odorless, crystalline solid.
Sodium bisulfide (NaSH [CAS: 16721-80-5]): Decomposes in the presence of water to form hydrogen sulfide (see p 224) and sodium hydroxide (see p 157). Highly corrosive and irritating to eyes, skin, and respiratory tract.				White crystalline substance with a slight odor of sulfur dioxide.
Sodium bisulfite (sodium hydrogen sulfite, NaHSO₃ [CAS: 7631-90-5]): Irritating to eyes, skin, and respiratory tract. Hypersensitivity reactions (angioedema, bronchospasm, or anaphylaxis) may occur.	5 mg/m ³			White crystalline solid with a slight sulfur dioxide odor and disagreeable taste. Widely used as a food and chemical preservative.
Sodium fluoroacetate (compound 1080 [CAS: 62-74-8]): A highly toxic metabolic poison. Metabolized to fluorocitrate, which prevents the oxidation of acetate in the Krebs cycle. Human lethal oral dose ranges from 2 to 10 mg/kg. See also p 201.	0.05 mg/m ³ , S	2.5 mg/m ³		Fluffy white solid or a fine white powder. Sometimes dyed black. Hygroscopic. Odorless. Vapor pressure is negligible at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen fluoride. Has been used as a rodenticide.

Sodium hydroxide (NaOH [CAS: 1310-73-2]): A caustic alkali; may cause severe burns. Fumes or mists are highly irritating to eyes, skin, and respiratory tract. See also p 157.	2 mg/m ³ (C)	10 mg/m ³ ERPG-1: 0.5 mg/m ³ ERPG-2: 5 mg/m ³ ERPG-3: 50 mg/m ³	3 0 1 W	White solid that absorbs moisture. Odorless. Evolves great heat upon solution in water. Soda lye is an aqueous solution.
Sodium metabisulfite (sodium pyrosulfite [CAS: 7681-57-4]): Very irritating to eyes and skin upon direct contact. Dusts irritating to eyes and respiratory tract; pulmonary edema may result. Hypersensitivity reactions may occur.	5 mg/m ³			White powder or crystalline material with a slight odor of sulfur dioxide. Reacts to form sulfur dioxide in the presence of moisture.
Stibine (antimony hydride [CAS: 7803-52-3]): A potent hemolytic agent similar to arsine. Gases irritating to the lung; pulmonary edema may occur. Liver and kidney are secondary target organs. See also p 98.	0.1 ppm	5 ppm ERPG-2: 0.5 ppm ERPG-3: 1.5 ppm	4 4 2	Colorless gas. Odor similar to that of hydrogen sulfide but may not be a reliable warning property. Formed when acid solutions of antimony are treated with zinc or strong reducing agents.
Stoddard solvent (mineral spirits, a mixture of aliphatic and aromatic hydrocarbons [CAS: 8052-41-3]): Dermal absorption can occur. Vapors irritating to eyes and respiratory tract. A CNS depressant. Chronic overexposures associated with headache, fatigue, bone marrow hypoplasia, and jaundice. May contain a small amount of benzene. See also hydrocarbons, p 219.	100 ppm	20,000 mg/m ³	0 2 0	Colorless liquid. Kerosene-like odor and irritation are good warning properties. Vapor pressure is approximately 2 mm Hg at 20°C (68°F). Flammable.
Strychnine (CAS: 57-24-9): Neurotoxin binds to inhibitory, postsynaptic glycine receptors, which results in excessive motor neuron activity associated with convulsions and muscular hyperrigidity leading to respiratory impairment or paralysis. See also p 348.	0.15 mg/m ³	3 mg/m ³		White solid. Odorless. Vapor pressure is negligible at 20°C (68°F). Thermal-breakdown products include oxides of nitrogen. Commonly used as a rodenticide (gopher bait).
Styrene monomer (vinylbenzene [CAS: 100-42-5]): Irritating upon direct contact. Dermal absorption occurs. Vapors irritating to respiratory tract. A CNS depressant. Symptoms include headache, nausea, dizziness, and fatigue. Cases of peripheral neuropathy have been reported. Limited evidence for adverse effects on fetal development and cancer in test animals (IARC 2B).	20 ppm	700 ppm ERPG-1: 50 ppm ERPG-2: 250 ppm ERPG-3: 1000 ppm	2 3 2	Colorless viscous liquid. Sweet aromatic odor at low concentrations is an adequate warning property. Odor at high levels is acrid. Vapor pressure is 4.5 mm Hg at 20°C (68°F). Flammable. Inhibitor must be included to avoid explosive polymerization. Used in SBR, ABS, and SAN polymers.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <— 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Subtilisins (proteolytic enzymes of <i>Bacillus subtilis</i> [CAS: 1395-21-7]): Primary skin and respiratory tract irritants. Potent sensitizers causing primary bronchoconstriction and asthma.	0.06 µg/m ³ (C)			Light-colored powder. Occupational asthma associated with their introduction into detergent in a powder formulation.
Sulfur dioxide (CAS: 7446-09-5): Forms sulfurous acid upon contact with moisture. Strongly irritating to eyes and skin; burns may result. Extremely irritating to the respiratory tract; irritation of the upper airways has caused obstruction of the upper airways and pulmonary edema. Asthmatics are of documented increased sensitivity to the bronchoconstrictive effects of sulfur dioxide air pollution. See also p 350.	2 ppm	100 ppm ERPG-1: 0.3 ppm ERPG-2: 3 ppm ERPG-3: 15 ppm	3 0 0 (liquified)	Colorless gas. Pungent, suffocating odor with a "taste" and irritative effects that are good warning properties.
Sulfur hexafluoride (CAS: 2551-62-4): Considered to be essentially a nontoxic gas. Asphyxiation by the displacement of air is suggested as the greatest hazard.	1000 ppm			Odorless, colorless dense gas. May be contaminated with other fluorides of sulfur, including the highly toxic sulfur pentafluoride, which release HF or oxyfluorides on contact with moisture.
Sulfuric acid (oil of vitriol, H₂SO₄ [CAS: 7664-93-9]): Highly corrosive upon direct contact; severe burns may result. Breakdown may release sulfur dioxide (see p 350). Exposure to the mist can irritate the eyes, skin, and respiratory tract.	1 mg/m ³ , A2 (strong acid mists)	15 mg/m ³ ERPG-1: 2 mg/m ³ ERPG-2: 10 mg/m ³ ERPG-3: 30 mg/m ³	3 0 2 W	Colorless to dark brown heavy, oily liquid. Odorless. Eye irritation may be an adequate warning property. A strong oxidizer. Addition of water creates strong exothermic reaction. Vapor pressure is less than 0.001 mm Hg at 20°C (68°F).
Sulfur monochloride (CAS: 10025-67-9): Forms hydrochloric acid and sulfur dioxide (see p 350) upon contact with water; direct contact can cause burns. Vapors highly irritating to the eyes, skin, and the respiratory tract.	1 ppm (C)	5 ppm	3 1 1	Fuming, amber to red, oily liquid with a pungent, irritating, sickening odor. Eye irritation is a good warning property. Vapor pressure is 6.8 mm Hg at 20°C (68°F). Combustible. Breakdown products include hydrogen sulfide, hydrogen chloride, and sulfur dioxide.

Sulfur pentafluoride (disulfur decafluoride [CAS: 5714-22-7]): Vapors are extremely irritating to the lungs; causes pulmonary edema at low levels (0.5 ppm) in test animals.	0.01 ppm (C)	1 ppm	Colorless liquid or vapor with a sulfur dioxide-like odor. Vapor pressure is 561 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include sulfur dioxide and hydrogen fluoride.
Sulfur tetrafluoride (SF₄ [CAS: 7783-60-0]): Readily hydrolyzed by moisture to form sulfur dioxide (see p 350) and hydrogen fluoride (see p 221). Extremely irritating to the respiratory tract; pulmonary edema may occur. Vapors also highly irritating to eyes and skin.	0.1 ppm (C)		Colorless gas. Reacts with moisture to form sulfur dioxide and hydrogen fluoride.
Sulfuryl fluoride (Vikane, SO₂F₂ [CAS: 2699-79-8]): Irritating to eyes and respiratory tract; fatal pulmonary edema has resulted. Acute high exposure causes tremors and convulsions in test animals. Chronic exposures may cause kidney and liver injury and elevated fluoride. See also p 221.	5 ppm	200 ppm	Colorless, odorless gas with no warning properties. Chloropicrin, a lacrimator, is often added to provide a warning property. Thermal-breakdown products include sulfur dioxide and hydrogen fluoride. A widely used fumigant.
Sulprofos (O-ethyl O-[4-(methylthio)phenyl] S-propylphosphorodithioate [CAS: 35400-43-2]): An organophosphate anticholinesterase insecticide (see p 291).	1 mg/m ³		Tan-colored liquid with a characteristic sulfide odor.
Talc, containing no asbestos fibers or crystalline silica (CAS: 14807-96-6): A tissue irritant. Pulmonary aspiration may cause serious pneumonitis.	2 mg/m ³ (respirable dust; if talc contains asbestos fibers, see asbestos TLV)	1000 mg/m ³	
Tantalum compounds (as Ta): Of low acute toxicity. Dusts mildly irritating to the lungs.	5 mg/m ³ (metal and oxide dusts, as Ta)	2500 mg/m ³ (metal and oxide dusts, as Ta)	Metal is a gray-black solid, platinum-white if polished. Odorless. Tantalum pentoxide is a colorless solid. Used in aerospace and other specialty alloys.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <— 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Tellurium and compounds (as Te): Complaints of sleepiness, nausea, metallic taste, and garlicky odor on breath and perspiration associated with workplace exposures. Neuropathies have been noted in high-dose studies. Hydrogen telluride causes pulmonary irritation and hemolysis; however, its ready decomposition reduces likelihood of a toxic exposure. Some tellurium compounds are fetotoxic or teratogenic in test animals.	0.1 mg/m ³ (as Te)	25 mg/m ³ (as Te)		Metallic tellurium is a solid with a silvery-white or grayish luster.
Tellurium hexafluoride (CAS: 7783-80-4): Slowly hydrolyzes to release hydrofluoric acid (see p 221) and telluric acid. Extremely irritating to the eyes and respiratory tract; pulmonary edema may occur. Has caused headaches, dyspnea, and garlicky odor on the breath of overexposed workers.	0.02 ppm	1 ppm		Colorless gas. Offensive odor. Not combustible. Thermal-breakdown products include hydrogen fluoride.
Temephos (Abate, <i>O,O,O',O'</i>-tetramethyl <i>O,O</i>-thiodi-<i>p</i>-phenylene phosphorothioate [CAS: 3383-96-8]): Primary irritant of eyes, skin, and respiratory tract; a moderately toxic organophosphate-type cholinesterase inhibitor (see p 291). Well absorbed by all routes.	10 mg/m ³			
Terphenyls (diphenyl benzenes, triphenyls [CAS: 26140-60-3]): Irritating upon direct contact. Vapors and mists irritating to respiratory tract; pulmonary edema has occurred at very high levels in test animals. Animal studies also suggest a slight potential for liver and kidney injury.	5 mg/m ³ (C)	500 mg/m ³	0 1 0	White to light yellow crystalline solids. Irritation is a possible warning property. Vapor pressure is very low at 20°C (68°F). Combustible. Commercial grades are mixtures of <i>o</i> -, <i>m</i> -, and <i>p</i> -isomers.
1,1,1,2-Tetrachloro-2,2-difluoroethane (halocarbon 112a; refrigerant 112a [CAS: 76-11-9]): Of low acute toxicity. Very high air levels irritating to the eyes and respiratory tract. A CNS depressant at high levels. By analogy to other freons, may cause cardiac arrhythmias. High-dose studies in animals suggest possible kidney and liver injury. See also p 209.	500 ppm	2000 ppm		Colorless liquid or solid with a slight ether-like odor. Vapor pressure is 40 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen chloride and hydrogen fluoride.

1,1,2,2-Tetrachloro-1,2-difluoroethane (halocarbon 112; refrigerant 112 [CAS: 76-12-0]): Of low acute toxicity. Once used as an antihelminthic. Very high air levels cause CNS depression. Vapors mildly irritating. By analogy to other freons, may cause cardiac arrhythmias. See also p 209.	500 ppm	2000 ppm		Colorless liquid or solid with a slight ether-like odor. Odor is of unknown value as a warning property. Vapor pressure is 40 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen chloride and hydrogen fluoride.
1,1,2,2-Tetrachloroethane (acetylene tetrachloride [CAS: 79-34-5]): Dermal absorption may cause systemic toxicity. Vapors irritating to the eyes and respiratory tract. A CNS depressant. By analogy to other chlorinated ethane derivatives, may cause cardiac arrhythmias. May cause hepatic or renal injury. Limited evidence of carcinogenicity in test animals (IARC 3).	1 ppm, A3 S NIOSH CA	100 ppm		Colorless to light yellow liquid. Sweet, suffocating, chloroform-like odor is a good warning property. Vapor pressure is 8 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen chloride and phosgene.
Tetrachloroethylene (perchloroethylene [CAS: 127-18-4]): Irritating upon prolonged contact; mild burns may result. Vapors irritating to eyes and respiratory tract. A CNS depressant. By analogy to other trichloroethylene and other chlorinated solvents, may cause arrhythmias. May cause liver and kidney injury. Chronic overexposure may cause short-term memory loss and personality changes. Limited evidence of adverse effects on reproductive function in males and fetal development in test animals. Evidence for carcinogenicity in test animals (IARC 2B). See also p 359.	25 ppm, A3 NIOSH CA	150 ppm ERPG-1: 100 ppm ERPG-2: 200 ppm ERPG-3: 1000 ppm	2 0 0	Colorless liquid. Chloroform-like or ether-like odor and eye irritation are adequate warning properties. Vapor pressure is 14 mm Hg at 20°C (68°F). Not combustible. Thermal breakdown products include phosgene and hydrochloric acid. Used in the dry cleaning industry.
Tetrachloronaphthalene (Halowax [CAS: 1335-88-2]): Causes chloracne and jaundice. Stored in body fat. Dermal absorption occurs.	2 mg/m ³			White to light yellow solid. Aromatic odor of unknown value as a warning property. Vapor pressure is less than 1 mm Hg at 20°C (68°F). Thermal-breakdown products include hydrogen chloride and phosgene.
Tetraethyl-di-thionopyrophosphate (TEDP, sulfotepp [CAS: 3689-24-5]): An organophosphate anticholinesterase insecticide (see p 291). Well absorbed dermally.	0.2 mg/m ³ , S	10 mg/m ³		Yellow liquid with garlic odor. Not combustible. Thermal-breakdown products include sulfur dioxide and phosphoric acid mist.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Tetraethyl lead (CAS: 78-00-2): A potent CNS toxin. Dermally well absorbed. Can cause psychosis, mania, convulsions, and coma. Reports of reduced sperm counts and impotence in overexposed workers. See also p 238.	0.1 mg/m ³ (as Pb), S	40 mg/m ³ (as Pb)	3 2 3	Colorless liquid. May be dyed blue, red, or orange. Slight musty odor of unknown value as a warning property. Vapor pressure is 0.2 mm Hg at 20°C (68°F). Combustible. Decomposes in light. As a gasoline additive, heavy exposure can occur through inappropriate use of gasoline as a solvent and in substance abuse.
Tetraethyl pyrophosphate (TEPP [CAS: 107-49-3]): A potent organophosphate cholinesterase inhibitor (see p 291). Rapidly absorbed through skin.	0.05 mg/m ³ , S	5 mg/m ³		Colorless to amber liquid with a faint fruity odor. Slowly hydrolyzed in water. Vapor pressure is 1 mm Hg at 140°C (284°F). Not combustible. Thermal-breakdown products include phosphoric acid mist.
Tetrahydrofuran (THF, diethylene oxide [CAS: 109-99-9]): Mildly irritating upon direct contact. Vapors mildly irritating to eyes and respiratory tract. A CNS depressant at high levels. A liver and kidney toxin at high doses in test animals.	200 ppm	2000 ppm [LEL]	2 3 1	Colorless liquid. The ether-like odor is detectable well below the TLV and provides a good warning property. Flammable. Vapor pressure is 145 mm Hg at 20°C (68°F).
Tetramethyl lead (CAS: 75-74-1): A potent CNS toxin thought to be similar to tetraethyl lead. See also p 238.	0.15 mg/m ³ (as Pb), S	40 mg/m ³ (as Pb)	3 3 3	Colorless liquid. May be dyed red, orange, or blue. Slight musty odor is of unknown value as a warning property. Vapor pressure is 22 mm Hg at 20°C (68°F).
Tetramethyl succinonitrile (TMSN [CAS: 3333-52-6]): A potent neurotoxin. Headaches, nausea, dizziness, convulsions, and coma have occurred in overexposed workers.	0.5 ppm, S	5 ppm		Colorless, odorless solid. Thermal-breakdown products include oxides of nitrogen.

Tetranitromethane (CAS: 509-14-8): Highly irritating upon direct contact; mild burns may result. Vapors extremely irritating to eyes and respiratory tract; pulmonary edema has been reported. May cause methemoglobinemia (see p 261). Liver, kidney, and CNS injury in test animals at high doses. Overexposure associated with headaches, fatigue, dyspnea. See also nitrates, p 279.	0.005 ppm, A3	4 ppm	Colorless to light yellow liquid or solid with a pungent, acrid odor. Irritative effects are a good warning property. Vapor pressure is 8.4 mm Hg at 20°C (68°F). Not combustible. A weak explosive and oxidizer. Highly explosive in the presence of impurities.
Tetrasodium pyrophosphate (CAS: 7722-88-5): Alkaline; dusts are mild irritants of eyes, skin, and respiratory tract.	5 mg/m ³		White powder. Alkaline in aqueous solution.
Tetryl (nitramine, 2,4,6-trinitrophenylmethylnitramine [CAS: 479-45-8]): Causes severe sensitization dermatitis. Dusts extremely irritating to the eyes and respiratory tract. Stains tissues bright yellow. May injure the liver and kidneys. Overexposures also associated with malaise, headache, nausea, and vomiting.	1.5 mg/m ³	750 mg/m ³	White to yellow solid. Odorless. A strong oxidizer. Vapor pressure is much less than 1 mm Hg at 20°C (68°F). Explosive used in detonators and primers.
Thallium (CAS: 7440-28-0) and soluble compounds (thallium sulfate, thallium acetate, thallium nitrate): A potent toxin causing diverse chronic effects including psychosis, peripheral neuropathy, optic neuritis, alopecia, abdominal pain, irritability, and weight loss. Liver and kidney injury may occur. Ingestion causes severe hemorrhagic gastroenteritis. Absorption possible by all routes. See also p 352.	0.1 mg/m ³ (as TI), S	15 mg/m ³ (as TI)	Appearance varies with the compound. The elemental form is a bluish-white, ductile heavy metal with a negligible vapor pressure. Thallium has been used as a rodenticide.
Thioglycolic acid (mercaptoacetic acid [CAS: 68-11-1]): Skin or eye contact with concentrated acid causes severe burns. Vapors irritating to eyes and respiratory tract.	1 ppm, S		Colorless liquid. Unpleasant mercaptan-like odor. Vapor pressure is 10 mm Hg at 18°C (64°F). Found in some coldwave and depilatory formulations.
Thiram (tetramethylthiuram disulfide [CAS: 137-26-8]): Dusts mildly irritating to eyes, skin, and respiratory tract. A moderate allergen and a potent skin sensitizer. Has disulfiram-like effects in exposed persons who consume alcohol (see p 186). Experimentally a goitrogen. Adverse effects on fetal development in test animals at very high doses.	1 mg/m ³	100 mg/m ³	White to yellow powder with a characteristic odor. May be dyed blue. Vapor pressure is negligible at 20°C (68°F). Thermal-breakdown products include sulfur dioxide and carbon disulfide. Used in rubber manufacture and as a fungicide.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <— 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Tin, metal, and inorganic compounds: Dusts irritating to the eyes, nose, throat, and skin. Prolonged inhalation may cause chest x-ray abnormalities. Some compounds react with water to form acids (tin tetrachloride, stannous chloride, and stannous sulfate) or bases (sodium and potassium stannate).	2 mg/m ³ (as Sn)	100 mg/m ³ (as Sn)		Metallic tin is odorless with a dull, silvery color.
Tin, organic compounds: Highly irritating upon direct contact; burns may result. Dusts, fumes, or vapors highly irritating to the eyes and respiratory tract. Triethyltin is a potent neurotoxin; triphenyltin acetate is highly hepatotoxic. Trialkyltins are the most toxic, followed in order by the dialkyltins and monoalkyltins. Within each of these classes, the ethyltin compounds are the most toxic. All are well absorbed dermally.	0.1 mg/m ³ (as Sn)	25 mg/m ³ (as Sn)		There are many kinds of organotin compounds: mono-, di-, tri-, and tetra-alkyltin and -aryltin compounds exist. Combustible. Organic tin compounds are used in some polymers and paints.
Titanium dioxide (CAS: 13463-67-7): A mild pulmonary irritant.	10 mg/m ³	5000 mg/m ³		White odorless powder. Rutile is a common crystalline form. Vapor pressure is negligible.
Tolidine (o-tolidine, 3,3'-dimethylbenzidine [CAS: 119-93-7]): A carcinogen in test animals (IARC 2B).	S, A3 NIOSH CA			White to reddish solid. Oxides of nitrogen are among thermal-breakdown products.
Toluene (toluol, methylbenzene [CAS: 108-88-3]): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant; may cause brain, kidney, and muscle damage with frequent intentional abuse. May cause cardiac arrhythmias. Liver and kidney injury with heavy exposures. Abusive sniffing during pregnancy associated with birth defects. See also p 357.	50 ppm, S	500 ppm ERPG-1: 50 ppm ERPG-2: 300 ppm ERPG-3: 1000 ppm	2 3 0	Colorless liquid. Aromatic, benzene-like odor detectable at very low levels. Irritation serves as a good warning property. Vapor pressure is 22 mm Hg at 20°C (68°F). Flammable.

Toluene 2,4-diisocyanate (CAS: 584-84-9) : A potent respiratory tract sensitizer (asthma) and potent irritant of the eyes, skin, and respiratory tract. Pulmonary edema has resulted with higher exposures. A carcinogen in test animals (IARC 2B). See also p 232.	0.005 ppm	2.5 ppm ERPG-1: 0.01 ppm ERPG-2: 0.15 ppm ERPG-3: 0.6 ppm	3 1 3 W	Colorless needles or a liquid with a sharp, pungent odor. Vapor pressure is approximately 0.04 mm Hg at 20°C (68°F). Combustible.
o-Toluidine (2-methylaniline [CAS: 95-53-4]) : A corrosive alkali; can cause severe burns. May cause methemoglobinemia (see p 261). Dermal absorption occurs. A carcinogen in test animals. (IARC 2A).	2 ppm, S, A3	50 ppm	3 2 0	Colorless to pale yellow liquid. The weak aromatic odor is thought to be a good warning property. Vapor pressure is less than 1 mm Hg at 20°C (68°F).
m-Toluidine (3-methylaniline [CAS: 108-44-1]) : A corrosive alkali; can cause severe burns. May cause methemoglobinemia (see p 261). Dermal absorption occurs.	2 ppm, S			Pale yellow liquid. Vapor pressure is less than 1 mm Hg at 20°C (68°F).
p-Toluidine (4-methylaniline [CAS: 106-49-0]) : A corrosive alkali; can cause severe burns. May cause methemoglobinemia (see p 261). Dermal absorption occurs. A carcinogen in test animals.	2 ppm, S, A3		3 2 0	White solid. Vapor pressure is 1 mm Hg at 20°C (68°F).
Tributyl phosphate (CAS: 126-73-8) : Highly irritating upon direct contact; causes severe eye injury and skin irritation. Vapors or mists irritating to the eyes and respiratory tract; high exposure in test animals caused pulmonary edema. Weak anticholinesterase activity. Headache and nausea are reported.	0.2 ppm	30 ppm	2 1 0	Colorless to pale yellow liquid. Odorless. Vapor pressure is very low at 20°C (68°F). Combustible. Thermal-breakdown products include phosphoric acid fume.
Trichloroacetic acid (CAS: 76-03-9) : A strong acid. A protein denaturant. Corrosive to eyes and skin upon direct contact.	1 ppm, A3			Deliquescent crystalline solid. Vapor pressure is 1 mm Hg at 51°C (123.3°F). Thermal-breakdown products include hydrochloric acid and phosgene.
1,2,4-Trichlorobenzene (CAS: 120-82-1) : Prolonged or repeated contact can cause skin and eye irritation. Vapors irritating to the eyes, skin, and respiratory tract. High-dose animal exposures injure the liver, kidneys, lungs, and CNS. Does not cause chloracne.	5 ppm (C)		2 1 0	A colorless liquid with an unpleasant, mothball-like odor. Vapor pressure is 1 mm Hg at 38.4°C (101.1°F). Combustible. Thermal-breakdown products include hydrogen chloride and phosgene.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
1,1,1-Trichloroethane (methyl chloroform, TCA [CAS: 71-55-6]): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant. May cause cardiac arrhythmias. Some dermal absorption occurs. Liver and kidney injury may occur. See also p 359.	350 ppm	700 ppm ERPG-1: 350 ppm ERPG-2: 700 ppm ERPG-3: 3500 ppm	2 1 0	Colorless liquid. Vapor pressure is 100 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen chloride and phosgene. Widely used chlorinated solvent.
1,1,2-Trichloroethane (CAS: 79-00-5): Dermal absorption may occur. Vapors mildly irritating to eyes and respiratory tract. A CNS depressant. May cause cardiac arrhythmias. Causes liver and kidney injury in test animals. Limited evidence for carcinogenicity in test animals (IARC 3). See also p 359.	10 ppm, S NIOSH CA	100 ppm	2 1 0	Colorless liquid. Sweet, chloroform-like odor is of unknown value as a warning property. Vapor pressure is 19 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include phosgene and hydrochloric acid.
Trichloroethylene (trichloroethene, TCE [CAS: 79-01-6]): Dermal absorption may occur. Vapors mildly irritating to eyes and respiratory tract. A CNS depressant. May cause cardiac arrhythmias. May cause cranial and peripheral neuropathies and liver damage. Has a disulfiram-like effect, "degreasers' flush" (see p 186). Reported to cause liver and lung cancers in mice (IARC 3). See also p 359.	50 ppm NIOSH CA	1000 ppm ERPG-1: 100 ppm ERPG-2: 500 ppm ERPG-3: 5000 ppm	2 1 0	Colorless liquid. Sweet chloroform-like odor. Vapor pressure is 58 mm Hg at 20°C (68°F). Not combustible at room temperatures. Decomposition products include hydrogen chloride and phosgene.
Trichlorofluoromethane (Freon 11 [CAS: 75-69-4]): Vapors mildly irritating to eyes and respiratory tract. A CNS depressant. May cause cardiac arrhythmias. See also p 209.	1000 ppm (C)			Colorless liquid or gas at room temperature. Vapor pressure is 690 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen chloride and hydrogen fluoride.
Trichloronaphthalene (Halowax [CAS: 1321-65-9]): Causes chloracne. A hepatotoxin at low doses, causing jaundice. Stored in body fat. Systemic toxicity may occur following dermal exposure.	5 mg/m ³ , S			Colorless to pale yellow solid with an aromatic odor of uncertain value as a warning property. Vapor pressure is less than 1 mm Hg at 20°C (68°F). Flammable. Decomposition products include phosgene and hydrogen chloride.

2,4,5-Trichlorophenoxyacetic acid (2,4,5-T [CAS: 93-76-5]): Moderately irritating to eyes, skin, and respiratory tract. Ingestion can cause gastroenteritis and injury to the CNS, muscle, kidney, and liver. A weak uncoupler of oxidative phosphorylation. Polychlorinated dibenzodioxin compounds are contaminants (see p 184). There are reports of sarcomas occurring in applicators. Adverse effects on fetal development in test animals.	10 mg/m ³	250 mg/m ³		Colorless to tan solid. Appearance and some hazardous properties vary with the formulation. Odorless. Vapor pressure is negligible at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen chloride and dioxins. A herbicide once widely used as a defoliant and in Vietnam, “Agent Orange.”
1,1,2-Trichloro-1,2,2-trifluoroethane (Freon 113): Vapors mildly irritating to eyes and mucous membranes. Very high air levels cause CNS depression and may injure the liver. May cause cardiac arrhythmias at air concentrations as low as 2000 ppm in test animals. See also p 209.	1000 ppm	2000 ppm		Colorless liquid. Sweetish, chloroform-like odor occurs only at very high concentrations and is a poor warning property. Vapor pressure is 284 mm Hg at 20°C (68°F). Not combustible. Thermal-breakdown products include hydrogen chloride, hydrogen fluoride, and phosgene.
Triethylamine (CAS: 121-44-8): An alkaline corrosive; highly irritating to eyes and skin; severe burns may occur. Vapors very irritating to eyes and respiratory tract; pulmonary edema may occur. High doses in animals cause heart, liver, and kidney injury. CNS stimulation possibly resulting from inhibition of monoamine oxidase.	1 ppm, S	200 ppm	3 3 0	Colorless liquid with a fishy, ammonia-like odor of unknown value as a warning property. Vapor pressure is 54 mm Hg at 20°C (68°F). Flammable.
Trifluorobromomethane (Halon 1301; Freon 13B1 [CAS: 75-63-8]): Extremely high air levels (150,000–200,000) can cause CNS depression and cardiac arrhythmias. See also p 209.	1000 ppm	40,000 ppm		Colorless gas with a weak ether-like odor at high levels and poor warning properties. Not combustible.
Trifluoromethane (Freon 23 [CAS: 75-46-7]): Vapors mildly irritating to the eyes and mucous membranes. Very high air levels cause CNS depression and cardiac arrhythmias. See also p 209.				Not combustible.
Trimellitic anhydride (TMAN [CAS: 552-30-7]): Dusts and vapors extremely irritating to eyes, nose, throat, skin, and respiratory tract. Potent respiratory sensitizer (asthma). Can also cause diffuse lung hemorrhage (pulmonary hemosiderosis).	0.04 mg/m ³ (C)			Colorless solid. Hydrolyzes to trimellitic acid in aqueous solutions. Vapor pressure is 0.000004 mm Hg at 25°C (77°F). TMAN is an important component of certain epoxy coatings.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <— 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Trimethylamine (CAS: 75-50-3): An alkaline corrosive; highly irritating upon direct contact; severe burns may occur. Vapors very irritating to respiratory tract.	5 ppm	ERPG-1: 0.1 ppm ERPG-2: 100 ppm ERPG-3: 500 ppm	3 4 0	Highly flammable gas with a pungent, fishy, ammonia-like odor. May be used as a warning agent in natural gas.
Trimethyl phosphite (phosphorous acid trimethylester [CAS: 121-45-9]): Very irritating upon direct contact; severe burns may result. Vapors highly irritating to respiratory tract. Cataracts have developed in test animals exposed to high air levels. Evidence for adverse effects on fetal development in test animals.	2 ppm		0 2 0	Colorless liquid with a characteristic, strong, fishy, or ammonia-like odor. Hydrolyzed in water. Vapor pressure is 24 mm Hg at 25°C (77°F). Combustible.
Trinitrotoluene (2,4,6-trinitrotoluene, TNT [CAS: 118-96-7]): Irritating upon direct contact. Stains tissues yellow. Causes sensitization dermatitis. Vapors irritating to the respiratory tract. May cause liver injury, methemoglobinemia (see p 261). Occupational overexposure associated with cataracts. Causes vasodilation, including coronary arteries. Headache and drop in blood pressure are common. Well absorbed by all routes. Tolerance to vasodilation can occur; cessation of exposure may precipitate angina pectoris in pharmacologically dependent workers. See also nitrates, p 279.	0.1 mg/m ³ , S	500 mg/m ³		White to light yellow crystalline solid. Odorless. Vapor pressure is 0.05 mm Hg at 85°C (185°F). Explosive upon heating or shock.
Triorthocresyl phosphate (TOCP [CAS: 78-30-8]): Inhibits acetylcholinesterase (see p 291). Potent neurotoxin causing delayed, partially reversible peripheral neuropathy by all routes.	0.1 mg/m ³ , S	40 mg/m ³		Colorless viscous liquid. Odorless. Not combustible. Although an anticholinesterase inhibitor, it is widely used as a chemical additive and in chemical synthesis.
Triphenyl phosphate (CAS: 115-86-6): Weak anticholinesterase activity in humans (see p 291). Delayed neuropathy reported in test animals.	3 mg/m ³	1000 mg/m ³	2 1 0	Colorless solid. Faint phenolic odor. Not combustible. Thermal-breakdown products include phosphoric acid fumes.

Tungsten and compounds: Few reports of human toxicity. Some salts may release acid upon contact with moisture. Chronic exposure to tungsten carbide cobalt amalgams in the hard-metals industry may be associated with fibrotic lung disease. See cobalt.	5 mg/m ³ (insoluble compounds) 1 mg/m ³ (soluble compounds)				Elemental tungsten is a gray, hard, brittle metal. Finely divided powders are flammable.	
Turpentine (CAS: 8006-64-2): Irritating to eyes upon direct contact. Dermal sensitizer. Dermal absorption occurs. Vapors irritating to respiratory tract. A CNS depressant at high air levels. See also hydrocarbons, p 219.	100 ppm	800 ppm	1	3	0	Colorless to pale yellow liquid with a characteristic paint-like odor that serves as a good warning property. Vapor pressure is 5 mm Hg at 20°C (68°F). Flammable.
Uranium compounds: Many salts are irritating to the respiratory tract; soluble salts are potent kidney toxins. Uranium is a weakly radioactive element (alpha emitter); decays to the radionuclide, thorium 230. Uranium has the potential to cause radiation injury to the lungs, tracheobronchial lymph nodes, bone marrow, and skin.	0.2 mg/m ³ (soluble and insoluble compounds, as U), A1	10 mg/m ³				Dense, silvery-white, lustrous metal. Finely divided powders are pyrophoric. Radioactive.
Valeraldehyde (pentanal [CAS: 110-62-3]): Very irritating to eyes and skin; severe burns may result. Vapors highly irritating to the eyes and respiratory tract.	50 ppm		1	3	0	Colorless liquid with a fruity odor. Flammable.
Vanadium pentoxide (CAS: 1314-62-1): Dusts or fumes highly irritating to eyes, skin, and respiratory tract. Acute overexposures have been associated with a persistent bronchitis and asthma-like responses, “boilermakers’ asthma.” Sensitization dermatitis reported. Low-level exposure may cause a greenish discoloration of the tongue, metallic taste, and cough.	0.05 mg/m ³	35 mg/m ³ (as V)				Yellow-orange to rust-brown crystalline powder or dark gray flakes. Odorless. Not combustible.
Vinyl acetate (CAS: 108-05-4): Highly irritating upon direct contact; severe skin and eye burns may result. Vapors irritating to the eyes and respiratory tract. Mild CNS depressant at high levels. Limited evidence for adverse effects on male reproduction in test animals at high doses.	10 ppm, A3	ERPG-1: 5 ppm ERPG-2: 75 ppm ERPG-3: 500 ppm	2	3	2	Volatile liquid with a pleasant fruity odor at low levels. Vapor pressure is 115 mm Hg at 25°C (77°F). Flammable. Polymerizes readily. Must contain inhibitor to prevent polymerization.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Vinyl bromide (CAS: 593-60-2): At high air levels, an eye and respiratory tract irritant and CNS depressant; a kidney and liver toxin. Animal carcinogen (IARC 2A).	0.5 ppm, A2 NIOSH CA		2 0 1	Colorless, highly flammable gas with a distinctive odor.
Vinyl chloride (CAS: 75-01-4): An eye and respiratory tract irritant at high air levels. Degeneration of distal phalanges with "acroosteolysis," Raynaud's disease, and scleroderma have been associated with heavy workplace overexposures. A CNS depressant at high levels; formerly used as an anesthetic. May cause cardiac arrhythmias. Causes angiosarcoma of the liver in humans (IARC 1).	1 ppm, A1 NIOSH CA		2 4 2	Colorless, highly flammable gas with a sweet ether-like odor. Polymerizes readily. Current potential exposure is limited to vinyl chloride synthesis and polymerization to PVC.
Vinyl cyclohexene dioxide (vinylhexane dioxide [CAS: 106-87-6]): Moderately irritating upon direct contact; severe burns may result. Vapors highly irritating to eyes and respiratory tract. Testicular atrophy, leukemia, and necrosis of the thymus in test animals. Topical application causes skin cancer in animal studies.	0.1 ppm, S, A3			Colorless liquid. Vapor pressure is 0.1 mm Hg at 20°C (68°F).
Vinyl toluene (methylstyrene [CAS: 25013-15-4]): Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels. Hepatic, renal, and hematologic toxicities observed at high doses in test animals. Limited evidence for adverse effects on the developing fetus at high doses.	50 ppm	400 ppm	2 2 2	Colorless liquid. Strong, unpleasant odor is considered to be an adequate warning property. Vapor pressure is 1.1 mm Hg at 20°C (68°F). Flammable. Inhibitor added to prevent explosive polymerization.
VM&P naphtha (varnish makers' and printers' naphtha; ligroin [CAS: 8032-32-4]): Vapors irritating to eyes and respiratory tract. A CNS depressant at high levels. May contain a small amount of benzene. See also hydrocarbons, p 219.	300 ppm, A3			Colorless volatile liquid.

Warfarin (CAS: 81-81-2): An anticoagulant by ingestion. Medicinal dosages associated with adverse effects on fetal development in test animals and humans. See also p 378.	0.1 mg/m ³	100 mg/m ³		Colorless crystalline substance. Odorless. Used as a rodenticide. Exposure is typically from inadvertent or deliberate ingestion, rather than through workplace contamination.
Xylene (mixture of <i>o</i>-, <i>m</i>-, <i>p</i>-dimethylbenzenes [CAS: 1330-20-7]): Vapors irritating to eyes and respiratory tract. A CNS depressant. By analogy to toluene and benzene, may cause cardiac arrhythmias. May injure kidneys. Limited evidence for adverse effects on fetal development in test animals at very high doses. See also p 357.	100 ppm	900 ppm	2 3 0	Colorless liquid or solid. Weak, somewhat sweet, aromatic odor. Irritant effects are adequate warning properties. Vapor pressure is approximately 8 mm Hg at 20°C (68°F). Flammable.
Xylidine (dimethylaniline [CAS: 1300-73-8]): May cause methemoglobinemia (see p 261). Dermal absorption may occur. Liver and kidney damage seen in test animals.	0.5 ppm, S, A3	50 ppm	3 1 0	Pale yellow to brown liquid. Weak, aromatic amine odor is an adequate warning property. Vapor pressure is less than 1 mm Hg at 20°C (68°F). Combustible. Thermal-breakdown products include oxides of nitrogen.
Yttrium and compounds (yttrium metal, yttrium nitrate hexahydrate, yttrium chloride, yttrium oxide): Dusts may be irritating to the eyes and respiratory tract.	1 mg/m ³ (as Y)	500 mg/m ³		Appearance varies with compound.
Zinc chloride (CAS: 7646-85-7): Caustic and highly irritating upon direct contact; severe burns may result. Ulceration of exposed skin from exposure to fumes has been reported. Fumes extremely irritating to respiratory tract; pulmonary edema has resulted.	1 mg/m ³ (fume)	50 mg/m ³		White powder or colorless crystals that absorb moisture. The fume is white and has an acrid odor. Exposure is principally through smoke bombs.
Zinc chromates (basic zinc chromate, ZnCrO₄; zinc potassium chromate, KZn₂(CrO₄)₂(OH); zinc yellow): Contains hexavalent chromium which is associated with lung cancer in workers. See also p 167.	0.01 mg/m ³ (as Cr), A1			Basic zinc chromate is a yellow pigment; dichromates are orange.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; SEN = potential sensitizer; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 532 for explanation of definitions.

(continued)

TABLE IV-4. HEALTH HAZARD SUMMARIES FOR INDUSTRIAL AND OCCUPATIONAL CHEMICALS (CONTINUED)

Health Hazard Summaries	ACGIH TLV	IDLH	NFPA Codes H F R	Comments
Zinc oxide (CAS: 1314-13-2): Fumes irritating to the respiratory tract. Causes metal fume fever (see p 259). Symptoms include headache, fever, chills, and muscle aches.	5 mg/m ³ (fume) 10 mg/m ³ (dusts)	500 mg/m ³		A white or yellowish-white powder. Fumes of zinc oxide are formed when elemental zinc is heated. Principal exposure is through brass foundries or welding on galvanized steel.
Zirconium compounds (zirconium oxide, ZrO₂; zirconium oxychloride, ZrOCl; zirconium tetrachloride, ZrCl₄): Zirconium compounds are generally of low toxicity. Some compounds are irritating; zirconium tetrachloride releases HCl upon contact with moisture. Granulomata caused by the use of deodorants containing zirconium have been observed. Dermal sensitization has not been reported.	5 mg/m ³ (as Zr)	50 mg/m ³ (as Zr)		The elemental form is a bluish-black powder or a grayish-white, lustrous metal. The finely divided powder can be flammable.

(C) = ceiling air concentration (TLV-C); S = skin absorption can be significant; A1 = ACGIH-confirmed human carcinogen; A2 = ACGIH-suspected human carcinogen; NFPA Hazard Codes: H = health, F = fire, R = reactivity, Ox = oxidizer, W = water-reactive, 0 (none) <—> 4 (severe). ERPG = Emergency Response Planning Guideline. See p 434 for explanation of definitions.

to molds, 268
- Allethrin. *See also* pyrethrins/pyrethroids, **322–324**
toxicity of, 323*t*
- Allium sativa (garlic), 216*t*. *See also* herbal and alternative products, **215–218**
drugs or toxins causing odor of, 32*t*
- Allopurinol, warfarin interaction and, 379*t*
- Allspice, Carolina, 312*t*. *See also* plants, **309–319**
- Allyl alcohol, hazard summary for, 535*t*
- Allyl chloride, hazard summary for, 535*t*
- Allyl glycidyl ether, hazard summary for, 535*t*
- Allyl propyl disulfide, hazard summary for, 535*t*
- Almonds, bitter. *See also* plants, **309–319**
cyanide causing odor of, 32*t*, 178
drugs or toxins causing odor of, 32*t*
toxicity of, 311*t*
- Alnus crispus, 311*t*. *See also* plants, **309–319**
- Alocasia macrorrhiza, 317*t*. *See also* plants, **309–319**
- Aloe vera/Aloe vera, 311*t*. *See also* plants, **309–319**
- Alpha-adrenergic agents
atrioventricular (AV) block caused by, 10*t*
bradycardia caused by, 10*t*
hyperkalemia caused by, 38*t*
hypertension caused by, 17
- Alpha-adrenergic blockers
hypotension caused by, 16*t*
for monoamine oxidase inhibitor overdose, 271
vasodilation caused by, 365
- Alpha-adrenergic syndrome, 29, 29*t*
- Alphagan. *See* brimonidine, 169–171
- Alpha glucosidase inhibitors. *See also* antidiabetic (hypoglycemic) agents, **93–96**
pharmacokinetics of, 94*t*
toxicity of, 93, 94*t*
- Alpha-latrotoxin, in black widow spider venom, 346
- Alpha-naphthylthiourea (ANTU), hazard summary for, 538*t*
- Alprazolam. *See also* benzodiazepines, **129–131**, **415–418**
pharmacokinetics of, 381*t*
toxicity of, 129, 130*t*
- Alprenolol. *See also* beta-adrenergic blockers, **131–133**
pharmacokinetics of, 381*t*
toxicity of, 132*t*
- Altace. *See* ramipril, 399*t*
- Altered mental status, in emergency evaluation/treatment, 2–3*t*, **19–25**
agitation, 24–25, 24*t*
coma and stupor, 19–20, 19*t*
delirium, 24–25, 24*t*
hyperthermia and, 21–22, 21*t*
hypothermia and, 20–21, 20*t*
psychosis, 24–25, 24*t*
seizures and, 22–24, 23*t*
- Alternaria spp. *See also* molds, **267–269**
toxicity of, 267

- Alternative remedies, toxicity of, **215–218**, 216–217*t*
- Altretamine. *See also* antineoplastic agents, **100–107**
toxicity of, 104*t*
- α -Alumina (aluminum oxide)
hazard summary for, 535*t*
impure (emery), hazard summary for, 567*t*
- Aluminum-containing antacids, for radiation poisoning, 330*t*
- Aluminum foil. *See also* nontoxic products, **286**
accidental exposure to, 287*t*
- Aluminum metal, hazard summary for, 536*t*
- Aluminum oxide (α -alumina)
hazard summary for, 535*t*
impure (emery), hazard summary for, 567*t*
- Aluminum phosphide, **306–307**
exposure limits for, 536*t*
hazard summary for, 536*t*
toxicity of, **306–307**
- Alupent. *See* metaproterenol, 134*t*
- Alveolitis, allergic (hypersensitivity pneumonitis), occupational causes of, 522
- Amanita* mushrooms, 272*t*. *See also* anticholinergic agents, **84–86**
acetylcysteine for poisoning caused by, 275, 405–407
bisporigera, toxicity of, 272*t*, 273–275
muscaria
tachycardia caused by, 13*t*
toxicity of, 272*t*
ocreata, toxicity of, 272*t*, 273–275
pantherina, toxicity of, 272*t*
phalloides, 272*t*, 273–275
hepatic failure caused by, 40*t*, 272*t*, 274
renal failure caused by, 39*t*
toxicity of, 272*t*, 273–275
silibinin (milk thistle) for poisoning caused by, 275, 500–501
smithiana
renal failure caused by, 39*t*, 273
toxicity of, 272*t*, 273
toxicity of, 272*t*
verna, toxicity of, 272*t*, 273–275
virosa, toxicity of, 272*t*, 273–275
- Amanitin
acetylcysteine for poisoning caused by, 405–407
silibinin (milk thistle) for poisoning caused by, 275, 500–501
toxicity of, 272*t*, 273–275
- Amantadine, **69–70**
delirium/confusion caused by, 24*t*
pharmacokinetics of, 69, 381*t*
toxicity of, **69–70**
- Amaryl. *See* glimepiride, 94*t*
- Amaryllis, 311*t*. *See also* plants, **309–319**
- Amaryllis belladonna*, 315*t*. *See also* plants, **309–319**
- Amatoxins, 272*t*, **273–275**
hypotension caused by, 16*t*
poisoning with mushrooms containing, 272*t*, **273–275**
acetylcysteine for, 275, 405–407
silibinin (milk thistle) for, 275, 500–501
rhabdomyolysis caused by, 27*t*
- Ambien. *See* zolpidem, 129, 130*t*
- Ambrosia artemisiifolia*, 316*t*. *See also* plants, **309–319**
- Ambulance transport, for victims of hazardous materials incident, 516
- Amen. *See* medroxyprogesterone, 103*t*
- Americaine. *See* benzocaine, 75, 75*t*, 76
- American Alder, 311*t*. *See also* plants, **309–319**
- American bittersweet, 311*t*. *See also* plants, **309–319**
- American Conference of Governmental Industrial Hygienists (ACGIH)
carcinogen classification by, 529
threshold limits values set by, 528
- American ivy, 311*t*. *See also* plants, **309–319**
- American mistletoe, 315*t*. *See also* plants, **309–319**

- Americium, DTPA for exposure to, 439–440
- Amikacin. *See also* antibacterial agents, **81–84**
pharmacokinetics of, 381*t*
toxicity of, 82*t*
- Amiloride. *See also* diuretics, **187–189**
pharmacokinetics of, 381*t*
toxicity of, 188*t*
- p*-Aminoaniline (phenylenediamine), hazard summary for, 602*t*
- Aminobenzene (aniline), hazard summary for, 537*t*
- p*-Aminobiphenyl (4-aminodiphenyl), hazard summary for, 536*t*
- Aminocarb. *See also* organophosphates and carbamates, **291–295**
toxicity of, 293*t*
- Aminocyclohexane (cyclohexylamine), hazard summary for, 556*t*
- 4-Amino-6-(1,1-dimethylethyl)-3-(methylthio)-1,2,4-triazin-5(4H)-one (metribuzin), hazard summary for, 594*t*
- 4-Aminodiphenyl, hazard summary for, 536*t*
- 2-Aminoethanol (ethanolamine), hazard summary for, 568*t*
- AminoFlex. *See* 1,4-butanediol, 210–213, 211*t*
- Aminoglycosides. *See also* antibacterial agents, **81–84**
renal failure caused by, 39*t*
toxicity of, 81, 82*t*
- 2-Aminonaphthalene (β -naphthylamine), hazard summary for, 595*t*
- Aminophylline, 354. *See also* theophylline, **354–356**
for bronchospasm, 9, 354
- 2-Aminopropane (isopropylamine), hazard summary for, 583*t*
- Aminopterin, teratogenic effects of, 59*t*
- 2-Aminopyridine, hazard summary for, 536*t*
- Aminoquinolines, **165–167**
pharmacokinetics of, 166
toxicity of, **165–167**
- 3-Amino-1,2,4-triazole (amitrole), hazard summary for, 536*t*
- 4-Amino-3,5,6-trichloropicolinic acid (picloram), hazard summary for, 605*t*
- Amiodarone. *See also* antiarrhythmic drugs, **78–81**
pharmacokinetics of, 381*t*
toxicity of, 79, 79*t*, 80
for ventricular arrhythmias, 15
ventricular arrhythmias caused by, 14*t*
warfarin interaction and, 379*t*
- Amiripityline. *See also* tricyclic antidepressants, **90–93**
with chlordiazepoxide, 90. *See also* benzodiazepines, **129–131**, **415–418**
elimination of, 56*t*
with perphenazine, 90
abdominal x-ray showing, 46*t*
pharmacokinetics of, 90, 381*t*
syndrome of inappropriate ADH secretion caused by, 36*t*
toxicity of, 88*t*, 90
in toxicology screens, 41*t*
interferences and, 43*t*
volume of distribution of, 56*t*, 381*t*
- Amitrole, hazard summary for, 536*t*
- Amiodipine. *See also* calcium antagonists, **144–147**
hypotension caused by, 16*t*
pharmacokinetics of, 381*t*
toxicity of, 144, 145*t*
- Ammonia, **70–72**. *See also* gases, irritant, **213–215**
chlorine mixtures and, chloramine gas released by, 70, 162
exposure limits for, 70, 214*t*, 537*t*
hazard summary for, 537*t*
job processes associated with exposure to, 521*t*
toxicity of, **70–72**, 214, 214*t*
- Ammonium bifluoride, 200*t*. *See also* fluoride, **200–201**
- Ammonium chloride, for radiation poisoning, 330*t*
- Ammonium chloroplatinate, hazard summary for, 605*t*
- Ammonium ichthiosulfonate (ichthammol). *See also* antiseptics/disinfectants, **109–111**
toxicity of, 109, 110
- Ammonium nitrate, toxicity of, 279–280
- Ammonium vanadyl tartrate (vanadium), 217*t*. *See also* herbal and alternative products, **215–218**
- Amnesic shellfish poisoning (domoic acid food poisoning), 205–207, 206*t*
- Amobarbital. *See also* barbiturates, **124–126**
pharmacokinetics of, 125*t*, 381*t*
toxicity of, 125*t*
- Amodiaquine, toxicity of, 165–167

- Amosite (asbestos), **121–122**
 exposure limits for, 121, 538t
 hazard summary for, 538t
 toxicity of, **121–122**
- Amoxapine. *See also* tricyclic antidepressants, **90–93**
 hyperthermia caused by, 21t
 pharmacokinetics of, 381t
 seizures caused by, 23t
 toxicity of, 88t
- Amoxicillin. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 381t
 toxicity of, 83t
- Amoxil. *See* amoxicillin, 83t
- Amphetamines, **72–74**, 73t
 agitation caused by, 24t
 in drug-assisted assault, 64t
 dyskinesias caused by, 26t
 hypertension caused by, 17, 18t, 74
 hyperthermia caused by, 21t, 73
 monoamine oxidase inhibitor interaction and, 270t
 mydriasis caused by, 30t
 neuromuscular blocking agents for overdoses of, 472–475
 pharmacokinetics of, 72, 381t
 phenolamine for overdose of, 487–488
 propranolol for overdose of, 496–497
 psychosis caused by, 24t
 renal failure caused by, 39t
 rhabdomyolysis caused by, 27t, 39t
 seizures caused by, 23t
 tachycardia caused by, 13t, 14t, 74
 toxicity of, **72–74**, 73t
 in toxicology screens, 41t, 73–74
 “drugs of abuse” panel, 42t
 interferences and, 43t, 73–74
 ventricular arrhythmias caused by, 14t
- Ampicillin. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 382t
 toxicity of, 83t
- Amprenavir. *See also* antiviral and antiretroviral agents, **111–115**
 pharmacokinetics of, 382t
 toxicity of, 113t
- Amrinone. *See* inamrinone, **454–455**
- Amygdalin. *See also* cyanide, **177–179**
 toxicity of, 177
- n*-Amyl acetate, hazard summary for, 537t
- sec*-Amyl acetate, hazard summary for, 537t
- Amyl nitrite, **476–477**
 for cyanide poisoning, 178, 476–477
 pharmacology/use of, **476–477**
 toxicity of, 279–280, 476
- Anabolic steroids, 216t. *See also* herbal and alternative products, **215–218**
 warfarin interaction and, 379t
- Anacin. *See*
 aspirin, 331–333
 caffeine, **142–144**
- Anacin-3. *See* acetaminophen, **66–69**

 local, **74–77**, 75t
 amide-type, 75–76, 75t
 confusion caused by, 24t
 delirium caused by, 24t
 ester-type, 75, 75t
 for nasotracheal intubation, 5
 pharmacokinetics of, 75–76
 seizures caused by, 23t
 toxicity of, **74–77**
 malignant hyperthermia caused by, 22
 propofol as, 494–496
 reproductive disorders associated with exposure to, 523
 “Angel dust” (slang). *See* phencyclidine, **300–302**
- Angel hair. *See also* low-toxicity products, **286**
 accidental exposure to, 288t
- Angel’s trumpet, 311t. *See also* plants, **309–319**
- Angina pectoris, nitrate exposure and, 279
- Angioedema, angiotensin blockers/ACE inhibitors causing, 77, 78
- Angiotensin blockers/ACE (angiotensin converting enzyme) inhibitors, **77–78**
 hyperkalemia caused by, 38t, 77
 pharmacokinetics of, 77
 toxicity of, **77–78**
- Anhydrous sodium tetraborate (borates), **135–136**
 hazard summary for, 541t
 toxicity of, **135–136**
- Aniline, hazard summary for, 537t
- “Animal tranquilizer” (slang). *See* phencyclidine, **300–302**
- Anion gap metabolic acidosis, 33–34, 34t
 drugs and toxins causing, 34t
 metformin causing, 34t, 93, 95
 osmolar gap with, 32, 33
- Anionic detergents, toxicity of, 181–183
- o*-Anisidine, hazard summary for, 537t
- Anisotropine. *See also* anticholinergic agents, **84–86**
 pharmacokinetics of, 382t
 toxicity of, 85t
- Ant (Formicidae) bites, 225–226
- Antabuse. *See* disulfiram, **186–187**
- Antacids
 accidental ingestion of, 287t. *See also* low-toxicity products, **286**
 aluminum-containing, for radiation poisoning, 330t
 calcium-containing. *See* calcium, **424–426**
 magnesium-containing. *See* magnesium, **250–251**, **463–464**
- Anthophyllite (asbestos), **121–122**
 exposure limits for, 121, 538t
 hazard summary for, 538t
 toxicity of, **121–122**
- Anthraquinone, 310t. *See also* plants, **309–319**
- Anthrax, as biological weapon, 367, 368, 369t, 371. *See also* warfare agents, biological, **367–372**
- Anthurium (*Anthurium* spp), 311t. *See also* plants, **309–319**
- Antiangiogenesis. *See also* antineoplastic agents, **100–107**
 toxicity of, 103t
- Antiarrhythmic drugs, **78–81**, 79t, **324–326**, 324t
 bicarbonate for overdose of, 80, 419–420
 pharmacokinetics of, 79, 324t
 toxicity of, **78–81**, **324–326**, 324t
 type I agents, 78, 79t
 type Ia agents, 78, 79t, **324–326**, 324t
 type Ib agents, 78, 79t

- Arisaema* spp, 313*t*, 314*t*. *See also* plants, **309–319**
- Aristolochia fangchi*, 218. *See also* herbal and alternative products, **215–218**
- Aroclor 1242 (polychlorinated biphenyls), **319–320**
 exposure limits for, 319, 606*t*
 hazard summary for, 606*t*
 hepatic failure caused by, 40*t*
 teratogenic effects of, 59*t*
 toxicity of, **319–320**
- Aromatase inhibitors. *See also* antineoplastic agents, **100–107**
 toxicity of, 103*t*
- Aromatic hydrocarbons
 particulate polycyclic, hazard summary for, 552*t*
 toxicity of, 219, 219*t*
 ventricular arrhythmias caused by, 14*t*, 15
- Aromatic odor, pungent, drugs or toxins causing, 32*t*
- Arrhythmias, 9. *See also* tachycardia/tachyarrhythmias, **12–13**, 12*t*, 13*t*
 drugs for treatment of, **78–81**, 79*t*
 phenytoin, 488–489
 toxicity of, **78–81**
 hydrocarbons causing, 14*t*, 15, 526–527
 pseudoephedrine/ephedrine/decongestants causing, 322
 ventricular, 12*t*, **13–15**, 14*t*, 15*t*
 arsenic causing, 14*t*, 116
 drugs and toxins causing, 13–14, 14*t*
 treatment of, 15
 lidocaine for, 15, 462–463
- Arrowhead vine, 311*t*. *See also* plants, **309–319**
- ARS (acute radiation syndrome), 328
- Arsenic, **115–119**
 abdominal x-ray showing, 46*t*
 acetylcysteine for poisoning caused by, 405–407
 binding agents for, 53*t*, 118
 dimercaprol (BAL) for poisoning caused by, 118, 413–415
 exposure limits for, 116, 538*t*
 hazard summary for, 538*t*
 hepatic failure caused by, 40*t*
 hypotension caused by, 16*t*
 neuropathy caused by, 31*t*, 116
 occupational exposure to, 524
 odor caused by, 32*t*
 succimer (DMSA) for poisoning caused by, 118, 501–503
 toxicity of, **115–119**
 central nervous system effects of, 523
 unithiol (DMPS/2,3-dimercaptopropanol-sulfonic acid) for poisoning caused by, 118, 506–508
 ventricular arrhythmias caused by, 14*t*, 116
- Arsenic trioxide, 115. *See also* arsenic, **115–119**
 toxicity of, 115
- Arsenobetaine, in seafood, 117
- Arsenocholine, in seafood, 117
- Arsine, **119–121**
 dimercaprol (BAL) for poisoning caused by, 120–121, 413–415
 exposure limits for, 119, 538*t*
 hazard summary for, 538*t*
 hemolysis caused by, 119, 524
 job processes associated with exposure to, 521*t*
 renal failure caused by, 39*t*, 120
 toxicity of, **119–121**
- Artane. *See* trihexyphenidyl, 85*t*
- Artemesia* spp, 316*t*. *See also* plants, **309–319**
- Artemesia absinthium*, 318*t*. *See also* plants, **309–319**
- Arterial blood gases, in ventilatory failure, 7
- Arterial vasospasm
 amphetamines causing, 73, 74
 ergot derivatives causing, 189, 190
- Arterial dilation, hypotension caused by, 16*t*
- Articaine. *See also* anesthetics, local, **74–77**
 toxicity of, 75*t*
- Artificial airway, 4
- Artificial leather making, toxic exposures and, 521*t*
- Artificial nails, toxic exposures associated with application and removal of, 521*t*
- Arum (*Arum* spp), 311*t*. *See also* plants, **309–319**
- Asbestos, **121–122**
 exposure limits for, 121, 538*t*
 hazard summary for, 538*t*
 occupational exposure to, 522
 toxicity of, **121–122**
- Asbestosis, 121, 522
- Ascendin. *See* amoxapine, 88*t*
- Asclepias* spp, 315*t*. *See also* plants, **309–319**
- Asclepias syriaca*, 317*t*. *See also* plants, **309–319**
- Ascorbic acid (vitamin C). *See also* vitamins, **366–367**
 for chromium poisoning, 168
 for methemoglobinemia, 263

- Ascorbic acid (vitamin C). *See also* vitamins (*cont.*)
for selenium poisoning, 339
toxicity of, 366–367
- Ash₂ (arsine), **119–121**
dimercaprol (BAL) for poisoning caused by, 120–121, 413–415
exposure limits for, 119, 538t
hazard summary for, 538t
hemolysis caused by, 119, 524
job processes associated with exposure to, 521t
renal failure caused by, 39t, 120
toxicity of, **119–121**
- Ashes. *See also* nontoxic products, **286**
cigarette, accidental exposure to, 287t
wood/fireplace, accidental exposure to, 287t
- Ash tree, 311t. *See also* plants, **309–319**
- Asp (Cleopatra's) envenomation, 343t. *See also* snakebites, **343–346**
- Asparaginase. *See also* antineoplastic agents, **100–107**
toxicity of, 105t
- Aspartame. *See also* nontoxic products, **286**
accidental exposure to, 287t
- Aspen, 311t. *See also* plants, **309–319**
- Aspergillus* spp. *See also* molds, **267–269**
toxicity of, 267
- Asphalt fumes, hazard summary for, 539t
- Asphyxia
in nitrous oxide toxicity, 283
in smoke inhalation, 341, 342
- Asphyxiants, occupational exposure to, 523, 524
- Aspiration
gastric contents, hypoxia caused by, 7t, 8
hydrocarbon, 219, 220, 221, 527
bronchospasm caused by, 9t
hypoxia caused by, 7t, 8
- Aspirin. *See also* salicylates, **331–333**
pharmacokinetics of, 382t
toxicity of, 331
- Astemizole. *See also* antihistamines, **96–98**
pharmacokinetics of, 96, 382t
QT prolongation/torsade de pointes caused by, 14t, 98
toxicity of, 97t, 98
withdrawal of from market, 98
- Asthma
molds causing, 268
work-related, 520–522
- Atabrine. *See*
primaquine, 165–167
quinacrine, 165–167
- Atapryl. *See* selegiline, 269–271
- Atenolol. *See also* beta-adrenergic blockers, **131–133**
pharmacokinetics of, 382t
toxicity of, 132t
- Atherosclerotic heart disease, occupational causes of, 523
- Ativan. *See* lorazepam, 130t, **415–418**
- Atracurium. *See also* neuromuscular blocking agents, **472–475**
pharmacology/use of, 473t, 475
- Atrazine, hazard summary for, 539t
- Atrioventricular (AV) block, **10–11**, 10t
beta-adrenergic blockers causing, 10t, 132
cardiac (digitalis) glycosides causing, 10t, 156
drugs and toxins causing, 10, 10t
hypertension with, drugs and toxins causing, 18t
pseudoephedrine/ephedrine/decongestants causing, 10t, 321
QRS interval prolongation and, 11, 11t
treatment of, 10–11
atropine and glycopyrrolate for, 11, 412–413
isoproterenol for, 11, 458–459
- Atrohist Plus. *See*
atropine, 85t, **412–413**

 drugs and toxins causing, 9, 9*t*
 treatment of, 9
- Broom, 311*t*. *See also* plants, **309–319**
 scotch, 316*t*
- Brown recluse spider (*Loxosceles*) envenomation, 346–348
- Brugmansia arborea*, 311*t*, 314*t*. *See also* plants, **309–319**
- Bryonia* spp., 314*t*. *See also* plants, **309–319**
- Bubble bath. *See also* low-toxicity products, **286**
 accidental exposure to, 287*t*
- Bubble lights. *See also* low-toxicity products, **286**
 accidental exposure to, 288*t*
- Bubbles. *See also* low-toxicity products, **286**
 accidental exposure to, 287*t*
- Buckeye, 311*t*. *See also* plants, **309–319**
- Buckthorn (*Karwinskia humboldtiana*/coyotillo). *See also* plants, **309–319**
 neuropathy caused by, 31*t*
 toxicity of, 311*t*, 312*t*
- Buckthorn (*Rhamnus* spp.), 312*t*. *See also* plants, **309–319**
- Bucizine. *See also* antihistamines, **96–98**
 toxicity of, 97*t*
- “Buds” (slang). *See* marijuana, **252–254**
- Bufencarb. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 293*t*
- Bufferin. *See* aspirin, 331–333
- Bufo* spp toads
 cardiac glycosides in venom of, 155, 216*t*. *See also* cardiac (digitalis) glycosides, **155–157**; herbal and alternative products, **215–218**
- hallucinogens in skin of, 248*t*. *See also* hallucinogens, **247–249**
- Bufotenine (5-hydroxy-*N,N*-dimethyltryptamine). *See also* hallucinogens, **247–249**; herbal and alternative products, **215–218**
 toxicity of, 216*t*, 248*t*
- Bufotoxin, 155, 216*t*. *See also* cardiac (digitalis) glycosides, **155–157**; herbal and alternative products, **215–218**
- Bug-Geta Snail and Slug Pellits. *See* metaldehyde, **258**
- Bulimea, chronic ipecac intoxication and, 228, 229, 458
- Bumblebee (Bombidae) envenomation, 225–226
- Bumetanide. *See also* diuretics, **187–189**
 pharmacokinetics of, 383*t*
 toxicity of, 188*t*
- Bumex. *See* bumetanide, 188*t*
- Bunchberry, 312*t*. *See also* plants, **309–319**
- Bungarus* envenomation, 343*t*. *See also* snakebites, **343–346**
- Bupivacaine. *See also* anesthetics, local, **74–77**
 pharmacokinetics of, 383*t*
 toxicity of, 75*t*
- Bupropion, 88. *See also* antidepressants, noncyclic, **88–90**
 pharmacokinetics of, 383*t*
 seizures caused by, 23*t*, 89
 toxicity of, 88, 88*t*, 89
- Burdock root, 312*t*. *See also* plants, **309–319**
- Burning bush, 312*t*. *See also* plants, **309–319**
- Burnt lime (calcium oxide), hazard summary for, 545*t*
- Bush tea, 316*t*. *See also* plants, **309–319**
- BuSpar. *See* buspirone, 335*t*, 336

- Bupirone. *See also* sedative-hypnotics, **335–337**
monoamine oxidase inhibitor interaction and, 270*t*
pharmacokinetics of, 383*t*
toxicity of, 335*t*, 336
- Busulfan. *See also* antineoplastic agents, **100–107**
abdominal x-ray showing, 46*t*
teratogenic effects of, 59*t*
toxicity of, 101*t*
- Butabarbital. *See also* barbiturates, **124–126**
pharmacokinetics of, 125*t*, 383*t*
toxicity of, 125*t*
- Butacaine. *See also* anesthetics, local, **74–77**
toxicity of, 75*t*
- 1,3-Butadiene, hazard summary for, 542*t*
- Butamben. *See also* anesthetics, local, **74–77**
toxicity of, 75*t*
- 1,4-Butanediol (1,4-BD/GHB precursor), 210–213, 211*t*
pharmacokinetics of, 383*t*
- Butanethiol (*n*-butyl mercaptan), hazard summary for, 544*t*
- 2-Butanol acetate (*sec*-butyl acetate), hazard summary for, 543*t*
- 2-Butanone (methyl ethyl ketone), hazard summary for, 591*t*
- 2-Butenal (crotonaldehyde), hazard summary for, 554*t*
- Buthus* spp scorpion envenomation, 334–335
- Butisol. *See* butabarbital, 125*t*
- Butorphanol, 289, 289*t*. *See also* opiates/opioids, **286–291**
pharmacokinetics of, 383*t*
toxicity of, 289, 289*t*
- 2-Butoxyethanol (ethylene glycol monobutyl ether/butyl cellosolve/EGBE). *See also* glycols, **194–198**
hazard summary for, 542*t*
toxicity of, 196*t*
- Buttercups, 312*t*. *See also* plants, **309–319**
- Butter daisy, 312*t*. *See also* plants, **309–319**
- Button batteries, toxicity of, 157–159
- n*-Butyl acetate, hazard summary for, 542*t*
- sec*-Butyl acetate, hazard summary for, 543*t*
- tert*-Butyl acetate, hazard summary for, 543*t*
- n*-Butyl acrylate, hazard summary for, 543*t*
- n*-Butyl alcohol, hazard summary for, 543*t*
- sec*-Butyl alcohol, hazard summary for, 543*t*
- tert*-Butyl alcohol, hazard summary for, 543*t*
- Butylamine, hazard summary for, 543*t*
- Butyl cellosolve (ethylene glycol monobutyl ether/2-butoxyethanol/EGBE). *See also* glycols, **194–198**
hazard summary for, 542*t*
toxicity of, 196*t*
- 4-*tert*-Butyl-chlorophenyl *N*-methyl *O*-methylphosphoramidate (cruformate), hazard summary for, 554*t*
- tert*-Butyl chromate, hazard summary for, 544*t*
- n*-Butyl glycidyl ether, hazard summary for, 544*t*
- n*-Butyl lactate, hazard summary for, 544*t*
- n*-Butyl mercaptan, hazard summary for, 544*t*
- Butyl nitrite, toxicity of, 279–280
- o*-*sec*-Butylphenol, hazard summary for, 544*t*
- di-*n*-Butyl phosphate (dibutyl phosphate), hazard summary for, 558*t*
- p*-*tert*-Butyltoluene, hazard summary for, 544*t*
- Butyrophenones. *See also* antipsychotic drugs, **107–109**
dystonia caused by, 26*t*
seizures caused by, 23*t*
toxicity of, 107*t*
- Buxus* spp, 311*t*. *See also* plants, **309–319**
- BVM. *See* 1,4-butanediol, 210–213, 211*t*
- BZ, as chemical weapon, 373, 376. *See also* warfare agents, chemical, **372–378**
- Cactus (thorn)/Cactus, 312*t*. *See also* plants, **309–319**
- Cadmium (Cd), **141–142**
exposure limits for, 141, 545*t*
hazard summary for, 545*t*
job processes associated with exposure to, 521*t*
toxicity of, **141–142**
- Ca-DTPA, pharmacology/use of, **439–440**
- Cafergot. *See* caffeine, **142–144**
- ergotamine, 189–190
- Caffeine, **142–144**
agitation caused by, 24*t*
anion gap/lactic acidosis caused by, 34*t*
dyskinesias caused by, 26*t*
esmolol for overdose of, 144, 443–444
hyperglycemia caused by, 35*t*, 143
hypokalemia caused by, 38, 38*t*, 143, 144
hypotension caused by, 16*t*, 143, 144
pharmacokinetics of, 143, 383*t*
propranolol for poisoning caused by, 144, 496–497
psychosis caused by, 24*t*
repeat-dose activated charcoal for overdose of, 58*t*, 144
seizures caused by, 23*t*, 143
with sympathomimetics, 320
tachycardia caused by, 13*t*, 14*t*, 143, 144
toxicity of, **142–144**
in toxicology screens, 41*t*
ventricular arrhythmias caused by, 14*t*, 143
- Caffeineism, 143
- Caladium/*Caladium* spp, 312*t*. *See also* plants, **309–319**
- Caladryl. *See* pramoxine, 75*t*
- Calamine lotion. *See also* nontoxic products, **286**
accidental exposure to, 287*t*
- Calan. *See* verapamil, 144, 145, 145*t*, 146
- Calcium, **424–426**
binding agent for, 53*t*
for calcium antagonist overdose, 146, 424–426
for fluoride poisoning, 201, 424–426
for hydrogen fluoride and hydrofluoric acid poisoning/contamination, 47*t*, 223, 424–426
for hyperkalemia, 38, 424–426
for *Latrodectus* spider bites, 348
for magnesium overdose, 251, 424–426
for oxalic acid poisoning, 47*t*, 296, 424–426
pharmacology/use of, **424–426**
for phosphate containing detergent ingestion, 182
- Calcium antagonists, 78, **144–147**, 145*t*
atrioventricular (AV) block caused by, 10, 10*t*, 145
bradycardia caused by, 10, 10*t*, 145
calcium for overdose of, 146, 424–426
epinephrine for overdose of, 146, 442–443
glucagon for overdose of, 146, 449–450
glucose/dextrose with insulin (HIE) for overdose of, 146, 450–451, 455–456
hypotension caused by, 16*t*, 144–145, 145
inamrinone for overdose of, 146, 454–455
pharmacokinetics of, 145
toxicity of, **144–147**, 145*t*
- Calcium blockers. *See* calcium antagonists, **144–147**
- Calcium carbimide (calcium cyanamide), hazard summary for, 545*t*
- Calcium carbonate. *See also* calcium, **424–426**
in chalk. *See also* low-toxicity products, **286**
accidental exposure to, 287*t*
for oxalic acid poisoning, 296
pharmacology/use of, 424–426
in Tums antacids, abdominal x-ray showing, 46*t*
- Calcium channel blockers. *See* calcium antagonists, **144–147**
- Calcium chloride. *See also* calcium, **424–426**
for calcium antagonist overdose, 146, 424–426
for hyperkalemia, 38, 424–426
for oxalic acid poisoning, 296, 424–426
pharmacology/use of, 424–426
- Calcium cyanamide, hazard summary for, 545*t*
- Calcium EDTA (calcium disodium EDTA/calcium disodium edetate/calcium disodium versenate), **440–442**
for chromium poisoning, 168
for lead poisoning, 241, 440–442
pharmacology/use of, **440–442**
for radiation poisoning, 330*t*
- Calcium gluconate. *See also* calcium, **424–426**
for calcium antagonist overdose, 146, 424–426
for dermal hydrofluoric acid exposure, 223, 425
for fluoride poisoning, 201, 424–426
for hydrogen fluoride and hydrofluoric acid poisoning/contamination, 223
for hyperkalemia, 424–426
for oxalic acid poisoning, 296, 424–426
pharmacology/use of, 424–426
for radiation poisoning, 330*t*
- Calcium hydroxide, hazard summary for, 545*t*

- Calcium hypochlorite, for chemical weapons decontamination, 378
- Calcium oxalate. *See also* oxalic acid/oxalates, **295–296**
in plants, 295, 309, 318
renal failure and, 39
toxicity of, 295
- Calcium oxide, hazard summary for, 545*t*
- Calcium soaks, for chemical exposures to skin, 47*t*, 425
- Caliciviruses, food-borne gastroenteritis caused by, 203
- California geranium, 312*t*, 313*t*. *See also* plants, **309–319**
- California poppy, 312*t*. *See also* plants, **309–319**
- California privet, 312*t*. *See also* plants, **309–319**
- Californium, DTPA for exposure to, 439–440
- Calla lily, 312*t*. *See also* plants, **309–319**
wild, 317*t*
- Caltha palustris*, 315*t*, 317*t*. *See also* plants, **309–319**
- Calycanthus* spp., 312*t*. *See also* plants, **309–319**
- Camouquin. *See* amodiaquine, 165–167
- Camphene
chlorinated (toxaphene). *See also* chlorinated hydrocarbons, **161–162**
hazard summary for, 548*t*
toxicity of, 161*t*
- Campho-Phenique. *See*
camphor, **147–148**
phenols, **302–303**
- Camphor, **147–148**
hazard summary for, 545*t*
seizures caused by, 23*t*, 148
toxicity of, **147–148**, 219*t*
in children, 60*t*
- Camphorated oil. *See* camphor, **147–148**
- Campylobacter*, food poisoning/systemic infection caused by, 203, 204*t*. *See also* food poisoning, bacterial, **203–205**
- Cancer
arsenic exposure and, 117
occupational exposures and, 522–523, 522*t*
potential for drug/chemical causing, 427, 529
radiation exposure causing, 328
- Candesartan. *See also* angiotensin blockers/ACE inhibitors, **77–78**
pharmacokinetics of, 383*t*
toxicity of, 77
- Candle nut, 317*t*. *See also* plants, **309–319**
- Candles. *See also* nontoxic products, **286**
accidental exposure to, 287*t*
- Cannabinoids, 252. *See also* marijuana, **252–254**
in drug-assisted assault, 64*t*
toxicity of, 252, 253
- Cannabis (*Cannabis sativa*), 252, 312*t*, 315*t*. *See also* marijuana, **252–254**, plants, **309–319**
- Capecitabine. *See also* antineoplastic agents, **100–107**
toxicity of, 102*t*
- Caphaline ipecacuanha*, ipecac syrup derived from, 228
- Capoten. *See* captopril, 77
- Capozide. *See*
captopril, 77
hydrochlorothiazide, 188*t*
- Caprifoliaceae* family, 314*t*. *See also* plants, **309–319**
- Caprolactam, hazard summary for, 545*t*
- Capsaicin sprays. *See also* low-toxicity products, **286**
accidental exposure to, 288*t*
- Capsicum* spp., 312*t*. *See also* plants, **309–319**
- Capsicum annuum*, 315*t*. *See also* plants, **309–319**
- Captafol, hazard summary for, 546
- Captopril. *See also* angiotensin blockers/ACE inhibitors, **77–78**
pharmacokinetics of, 77, 383*t*
toxicity of, 77
- Caraway, 312*t*. *See also* plants, **309–319**
- Carbamates, **291–295**, 292–293*t*
atrioventricular (AV) block caused by, 10*t*
atropine and glycopyrrolate for poisoning caused by, 294, 412–413
bradycardia caused by, 10*t*
hypotension caused by, 16*t*
miosis caused by, 30*t*
pralidoxime (2-PAM)/oximes for poisoning with, 294–295, 492–494
seizures caused by, 23*t*
toxicity of, **291–295**, 292–293*t*
ventilatory failure caused by, 6*t*
- Carbamazepine, **148–150**
atrioventricular (AV) block caused by, 10*t*, 149
bradycardia caused by, 10*t*, 149
coma caused by, 19*t*, 149
dyskinesias caused by, 26*t*, 149
elimination of, 56*t*, 149
pharmacokinetics of, 149, 383*t*
quantitative levels/potential interventions and, 45*t*
repeat-dose activated charcoal for overdose of, 58*t*, 150
seizures caused by, 23*t*, 149
stupor caused by, 19*t*, 149
toxicity of, **148–150**
in toxicology screens, 41*t*
volume of distribution of, 55*t*, 56*t*, 149, 383*t*
warfarin interaction and, 379*t*
- Carbamate peroxide. *See also* low-toxicity products, **286**
accidental exposure to, 287*t*
- Carbaryl. *See also* organophosphates and carbamates, **291–295**
hazard summary for, 546*t*
pralidoxime (2-PAM)/oximes for poisoning with, 492–494
toxicity of, 293*t*
- Carbatrol. *See* carbamazepine, **148–150**
- Carbenicillin. *See also* antibacterial agents, **81–84**
pharmacokinetics of, 383*t*
toxicity of, 83*t*
- Carbinoxamine. *See also* antihistamines, **96–98**
pharmacokinetics of, 383*t*
toxicity of, 97*t*
- Carbodiimide (cyanamide), hazard summary for, 555*t*
- Carbofuran. *See also* organophosphates and carbamates, **291–295**
hazard summary for, 546*t*
toxicity of, 293*t*
- Carbolic acid (phenol), **302–303**. *See also* caustic and corrosive agents, **157–159**; hydrocarbons, **219–221**
exposure limits for, 302, 602*t*
hazard summary for, 602*t*
hepatic failure caused by, 40*t*, 158*t*
pharmacokinetics of, 302
seizures caused by, 23*t*, 158*t*, 303
topical treatment for exposure to, 47*t*, 303
toxicity of, 158*t*, 219*t*, **302–303**
- 2-Carbomethoxy-1-methylvinyl dimethyl phosphate (mevinphos). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 594*t*
toxicity of, 292*t*
- Carbon black, hazard summary for, 546*t*
- Carbon dioxide
hypoxia caused by, 7*t*
partial pressure of (pCO₂), in ventilatory failure, 7
- Carbon disulfide, **150–151**
atherosclerotic heart disease associated with, 523
as disulfiram metabolite, 150, 186
exposure limits for, 150–151, 546*t*
hazard summary for, 546*t*
job processes associated with exposure to, 521*t*
neuropathy caused by, 31*t*
toxicity of, **150–151**
- Carbonic anhydrase inhibitors. *See also* diuretics, **187–189**
toxicity of, 188*t*
- Carbon monoxide, **151–154**, 153*t*
acetylcysteine for poisoning caused by, 405–407
anion gap/lactic acidosis caused by, 34*t*
coma caused by, 19*t*, 152
confusion caused by, 24*t*, 152
delirium caused by, 24*t*
exposure limits for, 152, 547*t*
hazard summary for, 547*t*
hyperbaric oxygen therapy for poisoning caused by, 153, 153*t*, 482–484
in smoke inhalation, 342
hypoxia caused by, 7*t*, 8
methylene chloride metabolized to, 158*t*, 265
occupational exposure to, 521*t*, 523, 524
oxygen therapy for poisoning caused by, 153, 482–484

- rhabdomyolysis caused by, 27t
 seizures caused by, 23t
 in smoke inhalation, 342
 stupor caused by, 19t, 152
 tachycardia caused by, 13t
 teratogenic effects of, 59t
 toxicity of, **151–154**, 153t
 cardiovascular effects of, 152, 523
 central nervous system effects of, 152, 523
 Carbon tetrabromide, hazard summary for, 547t
 Carbon tetrachloride, **154–155**
 acetylcysteine for poisoning caused by, 155, 405–407
 exposure limits for, 154, 547t
 hazard summary for, 547t
 hepatic failure caused by, 40t, 154
 toxicity of, **154–155**
 Carbonyl chloride (phosgene), **305–306**. *See also* gases, irritant, **213–215**
 as chemical weapon, 305. *See also* warfare agents, chemical, **372–378**
 exposure limits for, 214t, 305, 603t
 hazard summary for, 603t
 hypoxia caused by, 7t
 job processes associated with exposure to, 521t
 toxicity of, 214, 214t, **305–306**
 Carbonyl fluoride, hazard summary for, 547t
 Carbophenothion. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292t
 Carboplatin. *See also* antineoplastic agents, **100–107**
 toxicity of, 105t
 Carbosulfan. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 293t
 Carboxyhemoglobin, quantitative levels/potential interventions and, 45t
 in carbon monoxide poisoning, 152, 153
 in methylene chloride poisoning, 266
 smoke inhalation and, 342
 Carboxylic acids. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
 toxicity of, 284t
 Carburetor cleaning, toxic exposures and, 521t
 Carcinogenic potential, evaluation of, 527, 529
 Cardene. *See* nicardipine, 144, 145t
 Cardiac arrest, hypothermia causing, 21
 Cardiac arrhythmias. *See* arrhythmias, 9. *See also* tachycardia/tachyarrhythmias, **12–13**, 12f, 13t
 drugs for treatment of, **78–81**, 79t
 phenytoin, 488–489
 toxicity of, **78–81**
 hydrocarbons causing, 14t, 15, 526–527
 pseudoephedrine/ephedrine/decongestants causing, 322
 ventricular, 12f, **13–15**, 14t, 15f
 arsenic causing, 14t, 116
 drugs and toxins causing, 13–14, 14t
 treatment of, 15
 lidocaine for, 15, 462–463
 Cardiac (digitalis) glycosides, **155–157**
 atrioventricular (AV) block caused by, 10t, 156
 bradycardia caused by, 10t, 156
 digoxin-specific antibodies for overdose of, 157, 434–436, 436t
 hyperkalemia caused by, 38, 38t, 156
 pharmacokinetics of, 156
 QRS interval prolongation caused by, 11t
 succinylcholine use and, 5
 toxicity of, **155–157**
 ventricular arrhythmias caused by, 14t, 156
 Cardiac output, in hypotension, 17
 Cardinal flower, 312t. *See also* plants, **309–319**
 Cardiogenic pulmonary edema, 8
 hypoxia in, 7t, 8
 Cardioquin. *See* quinidine, **324–326**
 Cardiotoxicity
 bicarbonate for, 419–420
 of opiates and opioids, 290
 of type Ia antiarrhythmic drugs, 325
 Cardiovascular disorders
 antipsychotic agents causing, 108
 arsenic causing, 116
 noncyclic antidepressants causing, 89
 occupational causes of, 522t, 523
 tricyclic antidepressants causing, 90, 91
 Cardizem. *See* diltiazem, 144, 145t
 Cardura. *See* doxazosin, 365–366
 Carisoprodol. *See also* skeletal muscle relaxants, **339–341**
 in drug-assisted assault, 64t
 dyskinesias caused by, 26t
 pharmacokinetics of, 383t
 toxicity of, 340, 340t
 in toxicology screens, 41t
 Carmustine (BCNU). *See also* antineoplastic agents, **100–107**
 toxicity of, 101t
 Carnation, 312t. *See also* plants, **309–319**
 L-Carnitine
 pharmacology/use of, **426–427**
 for valproic acid overdose, 364, 426
 Carnitor. *See* L-carnitine, **426–427**
 Carolina allspice, 312t. *See also* plants, **309–319**
 Carolina jasmine/Carolina jessamine (*Gelsemium semper-virens*), 314t. *See also* plants, **309–319**
 Carolina moonseed, 315t. *See also* plants, **309–319**
 Carprofen. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
 pharmacokinetics of, 384t
 toxicity of, 284t
 Car repair, toxic exposures and, 521t
 Carrots, drugs or toxins causing odor of, 32t
 Carteolol. *See also* beta-adrenergic blockers, **131–133**
 pharmacokinetics of, 384t
 toxicity of, 132t
 Cartridge filter respirators
 information about in occupational-exposure history, 519
 for personal protection during response in hazardous materials incidents, 515
 Cartrol. *See* carteolol, 132t
 Carum carvi, 312t. *See also* plants, **309–319**
 Carvedilol. *See also* beta-adrenergic blockers, **131–133**
 pharmacokinetics of, 384t
 toxicity of, 132t
 Cartridge filter respirators
 information about in occupational-exposure history, 519
 for personal protection during response in hazardous materials incidents, 515
 Cartrol. *See* carteolol, 132t
 Carum carvi, 312t. *See also* plants, **309–319**
 Carvedilol. *See also* beta-adrenergic blockers, **131–133**
 pharmacokinetics of, 384t
 toxicity of, 132t
 Carya illinoensis, 316t. *See also* plants, **309–319**
 Carybdea alata envenomation, 236–237
 Caryota urens, 314t. *See also* plants, **309–319**
 Cascade Automatic Dishwasher Detergent. *See*
 caustic and corrosive agents (chlorinated trisodium phosphate), **157–159**
 detergents (sodium phosphates; sodium silicates), **181–183**
 Cascara/Cascara sagrada, 216t, 312t. *See also* herbal and alternative products, **215–218**; plants, **309–319**
 Casodex. *See* bicalutamide, 103t
 Cassava, 177, 312t. *See also* cyanide, **177–179**; plants, **309–319**
 Cassia angustifolia/Cassia acutifolia, 217t. *See also* herbal and alternative products, **215–218**
 Castor bean, 312t. *See also* plants, **309–319**
 Cataflam. *See* diclofenac, 284t
 Catapres. *See* clonidine, **169–171**
 Catechol, hazard summary for, 547t
 Catha edulis, 314t. *See also* plants, **309–319**
 Catharanthus roseus, 316t. *See also* plants, **309–319**
 Cathartics
 abuse of, hypernatremia caused by, 36t
 for gastrointestinal decontamination, 52
 magnesium in, 250. *See also* magnesium, **250–251**, **463–464**
 Cationic detergents, toxicity of, 181–183, 181t
 Catnip, 312t. *See also* plants, **309–319**
 Caulk. *See also* nontoxic products, **286**
 accidental exposure to, 287t
 Caulophyllum thalictroides, 311t. *See also* plants, **309–319**
 Caustic agents, toxicity of, **157–159**, 158t
 Caustic lime (calcium hydroxide), hazard summary for, 545t
 CCL₄ (carbon tetrachloride), **154–155**
 acetylcysteine for poisoning caused by, 155, 405–407
 exposure limits for, 154, 547t
 hazard summary for, 547t
 hepatic failure caused by, 40t, 154
 toxicity of, **154–155**

- CCNU (lomustine). *See also* antineoplastic agents, **100–107**
toxicity of, **101t**
- Cd (cadmium), **141–142**
exposure limits for, **141**, **545t**
hazard summary for, **545t**
job processes associated with exposure to, **521t**
toxicity of, **141–142**
- Cefclor. *See* cefaclor, **82t**
- Cedar, **312t**. *See also* plants, **309–319**
- Cefaclor. *See also* antibacterial agents, **81–84**
pharmacokinetics of, **384t**
toxicity of, **82t**
- Cefamandole. *See also* antibacterial agents, **81–84**
pharmacokinetics of, **384t**
toxicity of, **82t**
- Cefazolin. *See also* antibacterial agents, **81–84**
pharmacokinetics of, **384t**
toxicity of, **82t**
- Cefditoren pivoxil, pharmacokinetics of, **384t**
- Cefmetazole. *See also* antibacterial agents, **81–84**
pharmacokinetics of, **384t**
toxicity of, **82t**
- Cefobid. *See* cefoperazone, **82t**
- Cefoperazone. *See also* antibacterial agents, **81–84**
pharmacokinetics of, **384t**
toxicity of, **82t**
- Cefotan. *See* cefotetan, **82t**
- Cefotetan. *See also* antibacterial agents, **81–84**
pharmacokinetics of, **384t**
toxicity of, **82t**
- Ceftriaxone. *See also* antibacterial agents, **81–84**
pharmacokinetics of, **384t**
toxicity of, **82t**
- Celastrus scandens*, **311t**. *See also* plants, **309–319**
- Celebrex. *See* celecoxib, **284t**, **285**
- Celecoxib. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
pharmacokinetics of, **384t**
toxicity of, **284t**, **285**
- Cellex. *See* citalopram, **88**, **88t**, **89**
- Celixa. *See* citalopram, **88**, **88t**, **89**
- Cellosolve. *See also* glycols, **194–198**
butyl (ethylene glycol monobutyl ether/2-butoxyethanol/EGBE)
hazard summary for, **542t**
toxicity of, **196t**
ethyl (ethylene glycol monoethyl ether/2-ethoxyethanol/EGEE)
hazard summary for, **569t**
toxicity of, **196t**
isopropyl (2-isopropoxyethanol), hazard summary for, **582t**
methyl (ethylene glycol monomethyl ether/2-methoxyethanol/EGME)
hazard summary for, **587t**
hematologic disorders caused by, **524**
toxicity of, **196t**
- Cellosolve acetate (2-ethoxyethyl acetate), hazard summary for, **569t**
- Cellular hypoxia, **7t**, **8**
coma and, **19t**
seizures and, **23t**
stupor and, **19t**
tachycardia and, **13t**
- Cellulose sodium phosphate, as binding agent, **53t**
- Celluplex. *See* 1,4-butanediol, **210–213**, **211t**
- Cement manufacture, toxic exposures and, **521t**
- Central nervous system
drugs depressing
antipsychotic agents, **107–109**
barbiturates, **124–126**, **125t**
as chemical weapons, **373**, **376**, **377**. *See also* warfare agents, chemical, **372–378**
coma and stupor caused by, **19t**
ethanol, **190–193**
isopropyl alcohol, **234–236**
noncyclic antidepressants, **88–90**
skeletal muscle relaxants, **339–340**
tricyclic antidepressants, **90–93**
drugs stimulating
amphetamines, **72–74**
as chemical weapons, **373**, **376**, **377**. *See also* warfare agents, chemical, **372–378**
neuromuscular blocking agents for overdose of, **472–475**
in toxicology screens, **41t**
in lead poisoning, **239**, **523**
in mushroom poisoning, **272t**
radiation exposure affecting, **329**
type Ia antiarrhythmic drugs affecting, **325**
- Central venous access, in assessment/management of circulatory problems, **10**
in hypotension, **17**
- Centruroides* spp envenomation, **334–335**
- Centruroides exilicauda* (bark scorpion) envenomation, **334–335**
- Century plant, **312t**. *See also* plants, **309–319**
- Cephaeline (in ipecac syrup), **228**, **457**
- Cephalic tetanus, **352**
- Cephaloridine. *See also* antibacterial agents, **81–84**
pharmacokinetics of, **384t**
toxicity of, **82t**
- Cephalosporins. *See also* antibacterial agents, **81–84**
toxicity of, **82t**
- Cephalothin. *See also* antibacterial agents, **81–84**
pharmacokinetics of, **384t**
toxicity of, **82t**
- Cerastes* envenomation, **343t**. *See also* snakebites, **343–346**
- Cerebyx. *See* fosphenytoin, **488–489**
- Cerivastatin, rhabdomyolysis caused by, **27t**
- Cerubidine. *See* daunorubicin, **101t**, **106**
- Cesium-137. *See also* radiation, ionizing, **327–331**
chelating/blocking agents for exposure to, **330t**
Prussian blue (ferric hexacyanoferrate) for exposure to, **330t**, **499**
- Cesium hydroxide (cesium hydrate), hazard summary for, **547t**
- Cestrum* spp, **314t**. *See also* plants, **309–319**
- Cetacaine. *See* benzocaine, **75**, **75t**, **76**
- Cetacaine spray. *See* benzocaine, **75**, **75t**, **76**
butamben, **75t**
tetracaine, **75t**
- Cetaflam. *See* diclofenac, **284t**
- Cetalkonium chloride. *See also* detergents, **181–183**
toxicity of, **181t**
- Cetirizine. *See also* antihistamines, **96–98**
pharmacokinetics of, **384t**
toxicity of, **97t**
- Cetrimide. *See also* detergents, **181–183**
toxicity of, **181t**, **182**
- Cetrimonium bromide. *See also* detergents, **181–183**
toxicity of, **181t**
- Cetylpyridinium chloride. *See also* detergents, **181–183**
toxicity of, **181t**
- CFCs (chlorofluorocarbons/freons), **209–210**
exposure limits for, **209**
propranolol for poisoning caused by, **210**, **496–497**
toxicity of, **209–210**
ventricular arrhythmias caused by, **14t**, **209**, **210**, **526–527**
- CG (phosgene), **305–306**. *See also* gases, irritant, **213–215**
as chemical weapon, **305**. *See also* warfare agents, chemical, **372–378**
exposure limits for, **214t**, **305**, **603t**
hazard summary for, **603t**
hypoxia caused by, **7t**
job processes associated with exposure to, **521t**
toxicity of, **214**, **214t**, **305–306**
- Chalcosis, **175**. *See also* copper, **175–177**
- Chalk (calcium carbonate). *See also* low-toxicity products, **286**
accidental exposure to, **287t**
- Chamomile/ *Chamomilla recutita*, **312t**. *See also* plants, **309–319**
- Charcoal
accidental exposure to, **287t**. *See also* nontoxic products, **286**
activated, **427–428**
drugs and toxins poorly adsorbed to, **50**, **52t**

- for gastrointestinal decontamination, 50–51, 52*t*
in pregnant patient, 59, 428
pharmacology/use of, **427–428**
repeat-dose, 52, 57, 58*t*, 427–428
for aldicarb poisoning, 295
for barbiturate overdose, 58*t*, 126
for carbamazepine overdose, 58*t*, 150
for colchicine overdose, 175
for dapsone overdose, 58*t*, 84, 181
drugs removed by, 58*t*
for enhanced elimination, 52, 57, 58*t*
for phenacyclidine overdose, 302
for salicylate overdose, 333
for thallium poisoning, 353, 354
for theophylline overdose, 58*t*, 356
for valproic acid overdose, 364
- Charcoal briquettes. *See also* nontoxic products, **286**
accidental exposure to, 287*t*
- Charcoal hemoperfusion. *See also* hemoperfusion, 56*t*, 57
for carbamazepine overdose, 150
for chloramphenicol overdose, 84
for dapsone overdose, 181
for phenylbutazone overdose, 286
- Chat, 314*t*. *See also* plants, **309–319**
- Cheese, monoamine oxidase inhibitor interaction and, 270*t*
- Chelation therapy
for arsenic poisoning, 118
for arsine gas poisoning, 120–121
for copper poisoning, 176
for iron poisoning, 231, 432–433
for lead poisoning, 240–241
prophylactic, 502
with succimer (DMSA), 241, 501–503
for radiation poisoning, 330, 331*t*
for thallium poisoning, 353
- Chemet. *See* succimer (DMSA), **501–503**
- Chemical Mace (α -chloroacetophenone/CN)
as chemical weapon, 375*t*. *See also* warfare agents, chemical, **372–378**
hazard summary for, 549*t*
toxicity of, 375*t*
- Chemical warfare agents, 291, **372–378**, 374–375*t*. *See also* organophosphates and carbamates, **291–295**
pralidoxime (2-PAM)/oximes for poisoning with, 377, 492–494
- CHEMTREC, for information on substance involved in hazardous materials incident, 512
- Cherry. *See also* plants, **309–319**
Jerusalem, 314*t*
ornamental, 315*t*
- “Cherry Meth” (slang). *See* gamma-hydroxybutyrate (GHB), 210–213, 211*t*
- Cherry pits, chewed, 312*t*. *See also* plants, **309–319**
- Chestnuts, horse, 314*t*. *See also* plants, **309–319**
- Chest x-ray
in caustic and corrosive agent injuries, 159
for endotracheal tube placement confirmation, 5, 6
- Chewing gum. *See also* nontoxic products, **286**
accidental exposure to, 287*t*
nicotine. *See also* nicotine, **277–278**
toxicity of, 277
- Chicken liver, monoamine oxidase inhibitor interaction and, 270*t*
- Child abuse, 58, 61
- Childproofing environment, in poisoning prevention, 60
- Children
bradycardia in, 10
fluid/saline therapy in, 10
hyperglycemia in, insulin for, 35
hyperkalemia in, dextrose with insulin for, 38
hypoglycemia in, dextrose for, 35, 95
nitrite/sodium nitrite use in, 477, 477*t*
poisoning in, **59–63**
acetaminophen, 66
intentional, 61
ipecac syrup for, 49, 458
lead, 238, 239, 241–242
Lomotil, 60*t*, 246
plant ingestion and, 309
prevention of, 60
propofol administration in, 495
succinylcholine use in, 5
tetanus immunization in, 504
vital signs in, 61–62, 61*t*
- Child-resistant containers, in poisoning prevention, 60
- Chili pepper, 312*t*. *See also* plants, **309–319**
- Chinaberry, 310*t*, 312*t*. *See also* plants, **309–319**
- Chinese chalk. *See also* pyrethrins/pyrethroids, **322–324**
toxicity of, 323
- Chinese elm, 313*t*. *See also* plants, **309–319**
- Chironex fleckeri* (box jellyfish) antivenom, 237
- Chironex fleckeri* (box jellyfish) envenomation, 236–237
- Chiropsalmus quadrumanus* (box jellyfish) envenomation, 236–237
- Chitosan, 216*t*. *See also* herbal and alternative products, **215–218**
- Chloracne
dioxins causing, 185
polychlorinated biphenyls (PCBs) causing, 319
- Chloral hydrate (trichloroethanol). *See also* sedative-hypnotics, **335–337**
abdominal x-ray showing, 46*t*
in drug-assisted assault, 64*t*
elimination of, 56*t*
esmolol for overdose of, 336, 443–444
odor caused by, 32*t*
pharmacokinetics of, 384*t*
propranolol for overdose of, 336, 496–497
toxicity of, 335*t*, 336
in toxicology screens, 41*t*
ventricular arrhythmias caused by, 14*t*, 15, 336
volume of distribution of, 56*t*, 384*t*
warfarin interaction and, 379*t*
- Chlorambucil. *See also* antineoplastic agents, **100–107**
teratogenic effects of, 59*t*
toxicity of, 101*t*
- Chloramine gas, ammonia and chlorine mixtures causing, 70, 162
- Chloramphenicol. *See also* antibacterial agents, **81–84**
pharmacokinetics of, 384*t*
toxicity of, 81, 82*t*, 84
- Chlorates, **159–161**
renal failure caused by, 39*t*
toxicity of, **159–161**
- Chlordane. *See also* chlorinated hydrocarbons, **161–162**
hazard summary for, 548*t*
toxicity of, 161, 161*t*
- Chlordecone (kepone). *See also* chlorinated hydrocarbons, **161–162**
hazard summary for, 583*t*
repeat-dose activated charcoal for overdose of, 58*t*
toxicity of, 161*t*
- Chlordiazepoxide. *See also* benzodiazepines, **129–131**, **415–418**
with amitriptyline, 90. *See also* tricyclic antidepressants, **90–93**
pharmacokinetics of, 384*t*
toxicity of, 130*t*
- Chlorfenvinphos. *See also* organophosphates and carbamates, **291–295**
toxicity of, 292*t*
- Chlorhexidine. *See also* antiseptics/disinfectants, **109–111**
toxicity of, 109, 110
- Chloride
in toxicology screens, interferences and, 43*t*
vinyl, hazard summary for, 626*t*
- Chlorinated camphene (toxaphene). *See also* chlorinated hydrocarbons, **161–162**
hazard summary for, 548*t*
toxicity of, 161*t*
- Chlorinated diphenyl oxide, hazard summary for, 548*t*
- Chlorinated hydrocarbons, **161–162**
binding agent for, 53*t*
cardiovascular disease caused by, 161, 523
central nervous system effects and, 161, 523
esmolol for poisoning caused by, 444
hepatic failure caused by, 40*t*, 161
job processes associated with exposure to, 521*t*
pharmacokinetics of, 161
propranolol for poisoning caused by, 496–497

- Chlorinated hydrocarbons (*cont.*)
 renal failure caused by, 39*t*, 161
 seizures caused by, 23*t*, 161
 toxicity of, **161–162**
 ventricular arrhythmias caused by, 14*t*, 162, 526–527
- Chlorine/chlorine gas, **162–164**. *See also* gases, irritant, **213–215**
 ammonia mixtures and, chloramine gas released by, 70, 162
 asthma caused by, 520–522
 bronchospasm caused by, 9*t*
 exposure limits for, 163, 214*t*, 548*t*
 hazard summary for, 548*t*
 hypoxia caused by, 7*t*
 job processes associated with exposure to, 521*t*
 toxicity of, **162–164**, 214, 214*t*
- Chlorine dioxide (chlorine peroxide)
 hazard summary for, 548*t*
 job processes associated with exposure to, 521*t*
- Chlorine trifluoride (chlorine fluoride), hazard summary for, 549*t*
- Chlormephos. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
- Chloroacetaldehyde, hazard summary for, 549*t*
- α -Chloroacetophenone, hazard summary for, 549*t*
- 4,4'-methylene-bis(2-Chloroaniline), hazard summary for, 590*t*
- Chlorobenzene, hazard summary for, 549*t*
- o*-Chlorobenzylidene malonitrile (CS)
 as chemical weapon, 375*t*. *See also* warfare agents, chemical, **372–378**
 hazard summary for, 549*t*
 toxicity of, 375*t*
- Chlorobromomethane, hazard summary for, 550*t*
- 2-Chloro-1,3-butadiene (β -chloroprene), hazard summary for, 551*t*
- Chlorodifluoromethane (Freon 22)
 hazard summary for, 550*t*
 toxicity of, 209–210
- Chlorodiphenyls (polychlorinated biphenyls/PCBs), **319–320**
 exposure limits for, 319, 606*t*
 hazard summary for, 606*t*
 hepatic failure caused by, 40*t*
 teratogenic effects of, 59*t*
 toxicity of, **319–320**
- 2-Chloroethanol (ethylene chlorohydrin), hazard summary for, 571*t*
- bis(2-Chloroethyl) ether (dichloroethyl ether), hazard summary for, 561*t*
- Chlorofluorocarbons (CFCs/freons), **209–210**
 exposure limits for, 209
 propranolol for poisoning caused by, 210, 496–497
 toxicity of, **209–210**
 ventricular arrhythmias caused by, 14*t*, 209, 210, 526–527
- Chloroform (trichloromethane), **154–155**
 acetylcysteine for poisoning caused by, 155, 405–407
 exposure limits for, 154, 550*t*
 hazard summary for, 550*t*
 methyl (1,1,1-trichloroethane)
 exposure limits for, 359–360, 622*t*
 hazard summary for, 622*t*
 toxicity of, 359–361
 toxicity of, **154–155**
- (Chloro-methyl)benzene (benzyl chloride), hazard summary for, 540*t*
- 2-Chloro-1-methylbenzene (*o*-chlorotoluene), hazard summary for, 551*t*
- bis(Chloromethyl) ether (BCME), hazard summary for, 550*t*
- Chloromethyl methyl ether (CMME), hazard summary for, 550*t*
- Chloromycetin. *See* chloramphenicol, 81, 82*t*, 84
- 1-Chloro-1-nitropropane, hazard summary for, 550*t*
- Chloropentafluoroethane, hazard summary for, 551*t*
- Chlorophacinone. *See also* warfarin, **378–380**
 in rodenticides, 378–380
 toxicity of, 378–380
- Chlorophen (pentachlorophenol), **298–300**
 exposure limits for, 299, 601*t*
 hazard summary for, 601*t*
 hyperthermia caused by, 21*t*
 toxicity of, **298–300**
- Chlorophenoxy herbicides, **164–165**
 rhabdomyolysis caused by, 27*t*, 164
 toxicity of, **164–165**
- 2-(2-Chlorophenyl)-2-(methylamino)cyclohexanone (ketamine), **300–302**
 in drug-assisted assault, 64*t*
 dyskinesias caused by, 26*t*
 pharmacokinetics of, 300–301, 391*t*
 toxicity of, **300–302**
- Chlorophyllum molybdites* mushrooms. *See also* mushroom poisoning, **271–275**
 toxicity of, 272*t*
- Chloropicrin, hazard summary for, 551*t*
- Chloroplatinates, ammonium/sodium, hazard summary for, 605*t*
- β -Chloroprene, hazard summary for, 551*t*
- 3-Chloro-1-propene (allyl chloride), hazard summary for, 535*t*
- Chloropropylene oxide (epichlorohydrin), hazard summary for, 568*t*
- Chloroquine, **165–167**
 diazepam for overdose of, 167, 415–418
 pharmacokinetics of, 166, 385*t*
 QRS interval prolongation caused by, 11*t*, 166
 toxicity of, **165–167**
 in children, 60*t*, 166
 ventricular arrhythmias caused by, 14*t*, 166
- Chlorothiazide. *See also* diuretics, **187–189**
 pharmacokinetics of, 385*t*
 toxicity of, 188*t*
- α -Chlorotoluene (benzyl chloride), hazard summary for, 540*t*
- o*-Chlorotoluene, hazard summary for, 551*t*
- Chlorphenesin, pharmacokinetics of, 385*t*
- Chlorpheniramine. *See also* antihistamines, **96–98**
 pharmacokinetics of, 385*t*
 toxicity of, 97*t*
 in toxicology screens, 41*t*
- Chlorprocaine. *See also* anesthetics, local, **74–77**
 toxicity of, 75*t*
- Chlorpromazine
 antipsychotic drugs, **107–109**
 for hyperthermia, 22
 pharmacokinetics of, 385*t*
 toxicity of, 107*t*
 in children, 60*t*
 in toxicology screens, 41*t*
- Chlorpropamide. *See also* antidiabetic (hypoglycemic) agents, **93–96**
 pharmacokinetics of, 385*t*
 syndrome of inappropriate ADH secretion caused by, 36*t*
 toxicity of, 93, 94*t*, 96
- Chlorprothixene. *See also* antipsychotic drugs, **107–109**
 pharmacokinetics of, 385*t*
 toxicity of, 107*t*
- Chlorpyrifos. *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 551*t*
 toxicity of, 292*t*
- Chlorthalidone. *See also* diuretics, **187–189**
 pharmacokinetics of, 385*t*
 toxicity of, 188*t*
- Chlor-Trimeton. *See* chlorpheniramine, 97*t*
- Chlorzoxazone. *See also* skeletal muscle relaxants, **339–341**
 pharmacokinetics of, 385*t*
 toxicity of, 340*t*
- Chocolate cyanosis, 262
- Chokecherry, 312*t*. *See also* plants, **309–319**
- Choking agents, as chemical weapons, 372, 373, 376. *See also* warfare agents, chemical, **372–378**
- Cholestyramine, warfarin interaction and, 379*t*
- Cholestyramine resin, as binding agent, 53*t*
- Cholinergic agents
 atrioventricular (AV) block caused by, 10*t*
 bradycardia caused by, 10*t*
 miosis caused by, 30*t*
 seizures caused by, 23*t*
- Cholinergic syndrome, in mushroom poisoning, 272*t*

- Cholinesterase inhibitors. *See also* organophosphates and carbamates, **291–295**
 bronchospasm caused by, 9, 9*t*
 as chemical weapons, 372, 374*t*. *See also* warfare agents, chemical, **372–378**
 neurotoxicity of, 523
 pralidoxime (2-PAM)/oximes for poisoning with, 294–295, 377, 492–494
- Chondroitin sulfate, 216*t*. *See also* herbal and alternative products, **215–218**
- Christmas rose, 312*t*. *See also* plants, **309–319**
- Christmas tree lights, methylene chloride in. *See* methylene chloride, 158*t*, **265–267**
- Christmas tree ornaments. *See also* low-toxicity products, **286**
 accidental exposure to, 288*t*
- Christmas tree preservatives. *See also* low-toxicity products, **286**
 accidental exposure to, 288*t*
- Chromates, hazard summary for, 552*t*
- Chrome yellow (lead chromate). *See also* chromium, **167–169**
 hazard summary for, 584*t*
- Chromic acid, 167–169
 exposure limits for, 167, 552*t*
 hazard summary for, 552*t*
 job processes associated with exposure to, 521*t*
 toxicity of, 167–169
- Chromic anhydride, toxicity of, 167–169
- Chromic oxide, toxicity of, 167–169
- Chromic sulfate, toxicity of, 167–169
- Chromium, **167–169**
 acetylcysteine for poisoning caused by, 168, 405–407
 exposure limits for, 167, 552*t*
 hazard summary for, 552*t*
 toxicity of, **167–169**
- Chromium (dietary supplement), 216*t*. *See also* herbal and alternative products, **215–218**
- Chromium picolinate. *See also* herbal and alternative products, **215–218**
 toxicity of, 167–169, 216*t*
- Chromium salts, insoluble, hazard summary for, 552*t*
- Chromium trioxide
 hazard summary for, 552*t*
 toxicity of, 167–169
- Chromyl chloride, hazard summary for, 552*t*
- Chrysanthemum/*Chrysanthemum* spp. *See also* plants, **309–319**
 pyrethrins derived from, 322
 toxicity of, 312*t*
- Chrysaoira quinquecirrha* (American sea nettle) envenomation, treatment of, 237
- Chrysotile (asbestos), **121–122**
 exposure limits for, 121, 538*t*
 hazard summary for, 538*t*
 toxicity of, **121–122**
- Cicutoxin (*Cicuta maculata*/water hemlock), 313*t*, 314*t*, 317*t*. *See also* plants, **309–319**
 odor caused by, 32*t*
 seizures caused by, 23*t*
- Cidofovir. *See also* antiviral and antiretroviral agents, **111–115**
 pharmacokinetics of, 385*t*
 toxicity of, 112*t*, 114
- Cigarette ashes. *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
- Cigarette filter tips (unsmoked). *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
- Cigarette smoking
 bupropion for cessation of, 88
 passive smoking and, hazard summary for, 568*t*
- Ciguatera, food poisoning caused by, 205–207, 206*t*
 mannitol for, 207, 464–465
- Cimetidine, **428–430**, 430*t*
 for anaphylactic/anaphylactoid reactions, 28, 428–430
 confusion caused by, 24*t*, 429
 delirium caused by, 24*t*
 pharmacology/use of, **428–430**, 430*t*
 for scombroid shellfish poisoning, 207, 428–430
 warfarin interaction and, 379*t*
- Cimicifuga* spp./*Cimicifuga racemosa*, 311*t*. *See also* plants, **309–319**
- Cinchonism, quinidine causing, 325
- Cinerin I or II (pyrethrum), hazard summary for, 609*t*
- Cinnabar ore, mercury in, 254. *See also* mercury, **254–257**
- Cinnamon oil. *See also* essential oils, **147–148**
 toxicity of, 147*t*
- Cinnarizine. *See also* antihistamines, **96–98**
 pharmacokinetics of, 385*t*
 toxicity of, 97*t*
- Cipro. *See* ciprofloxacin, 83*t*
- Ciprofloxacin. *See also* antibacterial agents, **81–84**
 for biological warfare agents, 372
 pharmacokinetics of, 385*t*
 toxicity of, 83*t*
- Circulation, in emergency evaluation/treatment, 2*f*, **9–18**
 bradycardia/atrioventricular (AV) block and, 10–11, 10*t*
 general assessment/initial treatment and, 9–10
 hypertension and, 17–18, 18*t*
 hypotension and, 16–17, 16*t*
 QRS interval prolongation and, 11–12, 11*t*, 12*f*, 13*f*
 tachycardia and, 12–13, 12*f*, 13*t*
 ventricular arrhythmias and, 12*f*, 13–15, 14*t*, 15*f*
- Cisapride, ventricular arrhythmias caused by, 14*t*
- Cisatracurium. *See also* neuromuscular blocking agents, **472–475**
 pharmacology/use of, 473*t*, 475
- Cismethrin. *See also* pyrethrins/pyrethroids, **322–324**
 toxicity of, 323*t*
- Cisplatin. *See also* antineoplastic agents, **100–107**
 acetylcysteine for nephrotoxicity caused by, 405–407
 extravasation of, 106
 toxicity of, 105*t*, 106
- Citalopram, 88. *See also* antidepressants, noncyclic, **88–90**
 toxicity of, 88, 88*t*, 89
- Citrate
 calcium for overdose of, 424–426
 seizures caused by, 23*t*
 ventricular arrhythmias caused by, 14*t*
- Citrovorum factor (leucovorin calcium), **460–461**, 461*t*
 pharmacology/use of, **460–461**, 461*t*
 for trimethoprim poisoning, 81, 460–461
- Citrus aurantium* (bitter orange), 216*t*. *See also* herbal and alternative products, **215–218**
- CK (cyanogen chloride)
 as chemical weapon, 373, 375*t*. *See also* warfare agents, chemical, **372–378**
 hazard summary for, 555*t*
 toxicity of, 373, 375*t*
- Cl (clearance), effectiveness of enhanced elimination and, 54–55, 56*t*
- Cladosporium* spp. *See also* molds, **267–269**
 toxicity of, 267
- Cladribine. *See also* antineoplastic agents, **100–107**
 toxicity of, 102*t*
- Clarithromycin, ventricular arrhythmias caused by, 14*t*
- Claritin. *See* loratadine, 97*t*
- Claritin-D (loratadine plus pseudoephedrine). *See* loratadine, 97*t*
 pseudoephedrine, **320–322**
- Claviceps purpurea*, 189. *See also* ergot derivatives, **189–190**
- Clay. *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
- Clearance (Cl), effectiveness of enhanced elimination and, 54–55, 56*t*
- Clemastine. *See also* antihistamines, **96–98**
 pharmacokinetics of, 385*t*
 toxicity of, 97*t*
- Clematis/Clematis* spp., 312*t*. *See also* plants, **309–319**
- Cleocin. *See* clindamycin, 82*t*
- Cleopatras' asp envenomation, 343*t*. *See also* snakebites, **343–346**
- Clidinium. *See also* anticholinergic agents, **84–86**
 pharmacokinetics of, 385*t*
 toxicity of, 85*t*
- Clindamycin. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 385*t*
 toxicity of, 82*t*

- Clinoril. *See* sulindac, 284*t*
- Clitocybe* mushrooms, 272*t*. *See also* mushroom poisoning, 271–275
- atropine and glycopyrrolate for poisoning with, 412–413
- cerusata*, muscarine toxicity and, 272*t*, 273
- clavipes*, coprine toxicity and, 272*t*
- dealbata*, muscarine toxicity and, 272*t*, 273
- Clobenzorex, amphetamine blood test interference and, 74
- Clofibrate, syndrome of inappropriate ADH secretion caused by, 36*t*
- Clomipramine. *See also* tricyclic antidepressants, 90–93
- monoamine oxidase inhibitor interaction and, 270*t*
- pharmacokinetics of, 385*t*
- toxicity of, 88*t*
- Clonazepam. *See also* benzodiazepines, 129–131, 415–418
- pharmacokinetics of, 385*t*
- toxicity of, 130*t*
- Clonidine, 169–171
- atrioventricular (AV) block caused by, 10*t*
- bradycardia caused by, 10*t*
- coma caused by, 19*t*, 170
- in drug-assisted assault, 64*t*
- hypertension caused by, 18*t*, 170
- hypotension caused by, 16*t*, 170
- miosis caused by, 30*t*, 170
- naloxone for overdose of, 170, 469–472
- pharmacokinetics of, 169, 385*t*
- phenolamine for hypertension after withdrawal of, 487–488
- stupor caused by, 19*t*, 170
- toxicity of, 169–171
- ventilatory failure caused by, 6*t*
- Clorazepate. *See also* benzodiazepines, 129–131, 415–418
- pharmacokinetics of, 385*t*
- toxicity of, 130*t*
- Clorox 2 Powdered Laundry Bleach. *See* detergents (sodium carbonate), 181–183
- Clorox Liquid Bleach. *See* hypochlorite, 162–164
- Clorpres. *See*
- chlorthalidone, 188*t*
- clonidine, 169–171
- Clostridium botulinum*, 136. *See also* botulism, 136–138
- adult intestinal colonization with, 136–138
- as biological weapon, 367, 368, 369*t*, 371. *See also* warfare agents, biological, 367–372
- Clostridium perfringens*, food poisoning caused by, 204*t*. *See also* food poisoning, bacterial, 203–205
- Clostridium tetani*, 351. *See also* tetanus, 351–352
- Clothing, protective, for response in hazardous materials incident, 515
- Clotrimazole cream. *See also* low-toxicity products, 286
- accidental exposure to, 287*t*
- Clove oil. *See also* essential oils, 147–148
- toxicity of, 147*t*
- Clover, sweet, 317*t*. *See also* plants, 309–319
- Clozapine. *See also* antipsychotic drugs, 107–109
- pharmacokinetics of, 385*t*
- rhabdomyolysis caused by, 27*t*
- seizures caused by, 23*t*
- toxicity of, 107*t*, 108
- Clozaril. *See* clozapine, 107*t*, 108
- CMME (chloromethyl methyl ether), hazard summary for, 550*t*
- CN (chemical mace/ α -chloroacetophenone/CN)
- as chemical weapon, 375*t*. *See also* warfare agents, chemical, 372–378
- hazard summary for, 549*t*
- toxicity of, 375*t*
- Cnidaria envenomation, 236–237
- CO. *See* carbon monoxide, 151–154
- Coal tar creosote. *See also* phenols, 302–303
- hazard summary for, 554*t*
- toxicity of, 302
- Coal tar pitch volatiles, hazard summary for, 552*t*
- Coal workers' pneumoconiosis, 522
- Cobalt/cobalt compounds, hazard summary for, 553*t*
- Cobalt hydrocarbonyl, hazard summary for, 553*t*
- Cobalt-tungsten carbide, fibrotic lung disease caused by, 522
- Cobra envenomation, 343*t*. *See also* snakebites, 343–346
- Cocaethylene. *See also* cocaine, 171–173
- toxicity of, 171
- Cocaine, 171–173
- agitation caused by, 24*t*, 171
- bromocriptine to reduce craving for, 422–424
- dyskinesias caused by, 26*t*
- with heroin (speedball), 171
- hypertension caused by, 18*t*, 172
- hyperthermia caused by, 21*t*, 172
- hypoxia caused by, 7*t*
- as local anesthetic, 74, 75*t*, 171. *See also* anesthetics, local, 74–77
- monoamine oxidase inhibitor interaction and, 270*t*
- mydriasis caused by, 30*t*
- for nasotracheal intubation, 5
- neuromuscular blocking agents for overdose of, 472–475
- pharmacokinetics of, 171, 385*t*
- phenolamine for overdose of, 173, 487–488
- propranolol for overdose of, 173, 496–497
- psychosis caused by, 24*t*
- renal failure caused by, 39*t*, 172
- rhabdomyolysis caused by, 27*t*, 39*t*, 172
- seizures caused by, 23*t*, 171
- tachycardia caused by, 13*t*, 14*t*, 172
- toxicity of, 75*t*, 171–173
- in toxicology screens, 41*t*
- "drugs of abuse" panel, 42*t*
- ventricular arrhythmias caused by, 14*t*, 172
- Cocculus carolinus*, 315*t*. *See also* plants, 309–319

hydrocarbons and, 526
- Derrin (rotenone), hazard summary for, 610*t*
- Derris root (rotenone), hazard summary for, 610*t*
- DES (diethylstilbestrol)
as antineoplastic agent. *See also* antineoplastic agents, **100–107**
toxicity of, 103*t*
teratogenic effects of, 59*t*
- Desferal. *See* deferoxamine, **432–433**
- Desiccants. *See also* nontoxic products, **286**
accidental exposure to, 287*t*
- Desiccated thyroid. *See also* thyroid hormone, **356–357**
pharmacokinetics of, 401*t*
toxicity of, 356–357, 356*t*
- Desipramine. *See also* tricyclic antidepressants, **90–93**
pharmacokinetics of, 90, 386*t*
toxicity of, 88*t*
in children, 60*t*
in toxicology screens, 41*t*
- Desloratadine. *See also* antihistamines, **96–98**
pharmacokinetics of, 386*t*
toxicity of, 97*t*
- Desoxyn. *See* methamphetamine, 72, 73*t*
- Desylrel. *See* trazodone, 88, 88*t*, 89
- DETA (diethylenetriamine), hazard summary for, 563*t*
- Detergents, toxicity of, **181–183**, 181*t*
- Devils ivy, 313*t*. *See also* plants, **309–319**
- Dextrin. *See* phenylpropanolamine, **320–322**
- Dexbrompheniramine. *See also* antihistamines, **96–98**
abdominal x-ray showing, 46*t*
pharmacokinetics of, 386*t*
toxicity of, 97*t*
- Dexchlorpheniramine. *See also* antihistamines, **96–98**
toxicity of, 97*t*
- Dexedrine (dextroamphetamine), 72, 73*t*. *See also* amphetamines, **72–74**
pharmacokinetics of, 386*t*
toxicity of, 72, 73*t*
- Dexfenfluramine, 72, 73*t*. *See also* amphetamines, **72–74**
pharmacokinetics of, 386*t*
toxicity of, 72, 73, 73*t*
withdrawal of from market, 72
- Dextroamphetamine (dexedrine), 72, 73*t*. *See also* amphetamines, **72–74**
pharmacokinetics of, 386*t*
toxicity of, 72, 73*t*
- Dextromethorphan, **183–184**, 287
agitation/psychosis caused by, 24*t*
monoamine oxidase inhibitor interaction and, 183, 270, 270*t*
pharmacokinetics of, 183, 386*t*
toxicity of, **183–184**, 287
in toxicology screens, 41*t*
- Dextrone (diquat), **296–298**
coma caused by, 19*t*

- hazard summary for, 567*t*
 pharmacokinetics of, 297
 stupor caused by, 19*t*
 toxicity of, **296–298**
- Dextrose.** *See also* glucose, **450–451**
 for circulatory problems, 10
 for coma and stupor, 19–20, 35, 450–451
 hyperglycemia caused by, 35*t*
 for hyponatremia with volume overload, 36
 for hypoglycemia, 35, 95, 450–451
 with insulin, for calcium antagonist overdose/hyperkalemia, 38, 450–451, 455–456
- Dextrostat** (dextroamphetamine). *See* amphetamines, **72–74**
- DGE** (diglycidyl ether), hazard summary for, 563*t*
- DHEA** (dihydroepiandrosterone), 216*t*. *See also* herbal and alternative products, **215–218**
- DHE-45** (dihydroergotamine)
 pharmacokinetics of, 387*t*
 toxicity of, 189–190
- Diabeta.** *See* glyburide, 93, 94*t*
- Diabetes insipidus, nephrogenic, lithium-induced,** 36, 244
- Diabetes mellitus**
 hyperglycemia in, 35*t*
 toxicity of agents in treatment of. *See* antidiabetic (hypoglycemic) agents, **93–96**
 Vacor (PNU) causing, 361
- Diabetic ketoacidosis**
 anion gap acidosis caused by, 33, 34*t*
 insulin for, 455–456
 osmolar gap elevation caused by, 32*t*, 33
- Diabinese.** *See* chlorpropamide, 93, 94*t*, 96
- Diacetone alcohol,** hazard summary for, 557*t*
- Diacetylmorphine** (heroin), 286, 289*t*. *See also* opiates/opioids, **286–291**
 with cocaine (speedball), 171. *See also* cocaine, **171–173**
 pharmacokinetics of, 390*t*
 toxicity of, 286, 289*t*
 withdrawal from, in neonates, 62–63
- Diagnosis of poisoning,** **3*t*, 28–45, 46*t***
 abdominal x-rays in, **45, 46*t***
 history in, **28–29**
 laboratory tests in, **31–40**
 physical examination in, **29–31**, 29*t*, 30*t*, 31*t*, 32*t*
 toxicology screening in, **40–45**
- Diagnostic tests**
 in diagnosis of poisoning, **31–40**. *See also* toxicology screening, **40–45**
 for occupational toxins, 524–525
 for substances used in drug-assisted assault, 64–65, 64*t*
- Dialifor.** *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
- Dialysis**
 for enhanced elimination, 55–57, 56*t*. *See also* hemodialysis, 55–57, 56*t*
 peritoneal, for enhanced elimination, 57
- Diamine** (hydrazine)
 hazard summary for, 578*t*
 hepatotoxicity of, 524
 job processes associated with exposure to, 521*t*
- p-Diaminobenzene** (phenylenediamine), hazard summary for, 602*t*
- p-Diaminodiphenyl** (benzidine), hazard summary for, 540*t*
- 4,4'-Diaminodiphenylmethane** (4,4'-methylene dianiline), hazard summary for, 591*t*
- Dianthus barbatus*, 317*t*.** *See also* plants, **309–319**
- Dianthus caryophyllus*, 312*t*.** *See also* plants, **309–319**
- Diapers, disposable.** *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
- Diaphoresis, in diagnosis of poisoning,** 31
- Diarrhea, food-borne organisms causing,** 203–205, 204*t*
- Diarrhetic shellfish poisoning,** 205–207, 206*t*
- Diatomaceous earth** (silica, amorphous), hazard summary for, 611*t*
- Diazepam, 415–418.** *See also* benzodiazepines, **129–131, 415–418**
 for agitation/delirium/psychosis, 25, 415–418
 for chloroquine overdose, 167, 415–418
 for drug/alcohol withdrawal, 192, 415–418
 for dyskinesia, 26
 for hyperthermia, 22
 for isoniazid overdose, 234
 pharmacokinetics of, 386*t*, 415
 pharmacology/use of, **415–418**
 for seizures, 24, 415–418
 for strychnine poisoning, 349, 415–418
 for tetanus, 352
 toxicity of, 129, 130, 130*t*, 416
- Diazinon.** *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 557*t*
 pralidoxime (2-PAM)/oximes for poisoning with, 492–494
 toxicity of, 292*t*
- Diazirine** (diazomethane), hazard summary for, 558*t*
- Diazomethane,** hazard summary for, 558*t*
- Diazoxide, 433–434**
 for antidiabetic agent overdose, 35, 95, 433–434
 hyperglycemia caused by, 35*t*, 434
 pharmacokinetics of, 386*t*
 pharmacology/use of, **433–434**
 toxicity of, 365–366
- Dibenzodiazepines.** *See also* antipsychotic drugs, **107–109**
 toxicity of, 107*t*
- Dibenzodioxins, polychlorinated (PCDDs), toxicity of,** 184–186
- Dibenzofurans (PCDFs), toxicity of,** 184–186
- Dibenzylamine.** *See* phenoxybenzamine, 365–366
- Diborane**
 hazard summary for, 558*t*
 job processes associated with exposure to, 521*t*
- Dibrom** (Naled/1,2-dibromo-2,2-dichloroethyl dimethyl phosphate). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 558*t*
 toxicity of, 292*t*
- Dibromochloropropane, reproductive disorders associated with exposure to,** 523
- 1,2-Dibromo-3-chloropropane (DBCP), hazard summary for,** 558*t*
- 1,2-Dibromo-2,2-dichloroethyl dimethyl phosphate (Naled).** *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 558*t*
 toxicity of, 292*t*
- Dibromodifluoromethane** (difluorodibromomethane/Freon 12B2), hazard summary for, 563*t*
- Dibromoethane/1,2-dibromoethane (EDB/ethylene dibromide), 193–194**
 exposure limits for, 193, 571*t*
 hazard summary for, 571*t*
 toxicity of, **193–194**
- Dibucaine.** *See also* anesthetics, local, **74–77**
 toxicity of, 75*t*
- Dibutyl phosphate, hazard summary for,** 558*t*
- Dibutyl phthalate, hazard summary for,** 559*t*
- Dicentra*, 311*t*.** *See also* plants, **309–319**
- Dichlorofenthion.** *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
- 1,2-Dichloroacetylene, hazard summary for,** 559*t*
- o*-Dichlorobenzene** (1,2-dichlorobenzene), hazard summary for, 559*t*
- p*-Dichlorobenzene** (1,4-dichlorobenzene), hazard summary for, 559*t*
- 3,3'-Dichlorobenzidine, hazard summary for,** 559*t*
- Dichloro** (2-chlorovinyl)arsine (lewisite)
 burns of eye caused by, dimercaprol (BAL) for, 413–415
 as chemical weapon, 115, 372, 373, 374*t*, 377. *See also* warfare agents, chemical, **372–378**
 toxicity of, 115, 372, 373, 374*t*
- Dichlorodifluoromethane** (Freon 12)
 hazard summary for, 559*t*
 toxicity of, 209–210
- 1,3-Dichloro-5,5-dimethylhydantoin, hazard summary for,** 560*t*
- Dichlorodiphenyltrichloroethane (DDT).** *See also* chlorinated hydrocarbons, **161–162**
 hazard summary for, 557*t*
 toxicity of, 161, 161*t*
- 1,1-Dichloroethane, hazard summary for,** 560*t*

- 1,2-Dichloroethane, hazard summary for, 560t
 1,2-Dichloroethene (1,2-dichloroethylene), hazard summary for, 560t
 1,1-Dichloroethylene, hazard summary for, 560t
 1,2-Dichloroethylene, hazard summary for, 560t
 Dichloroethyl ether, hazard summary for, 561t
 Dichloroethyl oxide (dichloroethyl ether), hazard summary for, 561t
 Dichlorofluoromethane (Freon 21)
 hazard summary for, 561t
 toxicity of, 209–210
 Dichloromethane (methylene chloride), **265–267**
 exposure limits for, 266, 591t
 hazard summary for, 591t
 job processes associated with exposure to, 521t
 toxicity of, 158t, **265–267**
 Dichloromonofluoromethane, toxicity of, 209–210
 1,1-Dichloro-1-nitroethane, hazard summary for, 561t
 2,4-Dichlorophenoxyacetic acid (2,4-D)
 in Agent Orange, 164
 hazard summary for, 561t
 toxicity of, 164–165
 1,2-Dichloropropane (propylene dichloride), hazard summary for, 607t
 1,3-Dichloropropene, hazard summary for, 561t
 2,2-Dichloropropionic acid, hazard summary for, 562t
 1,3-Dichloropropylene (1,3-dichloropropene), hazard summary for, 561t
 Dichlorotetrafluoroethane (Freon 114)
 hazard summary for, 562t
 toxicity of, 209–210
 2,2-Dichlorovinyl dimethyl phosphate (dichlorvos). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 562t
 pralidoxime (2-PAM)/oximes for poisoning with, 492–494
 toxicity of, 292t
 Dichlorphenamide. *See also* diuretics, **187–189**
 pharmacokinetics of, 386t
 toxicity of, 188t
 Dichlorvos (DDVP). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 562t
 pralidoxime (2-PAM)/oximes for poisoning with, 492–494
 toxicity of, 292t
 Dichromate salts, toxicity of, 167–169
 Diclofenac. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
 pharmacokinetics of, 386t
 toxicity of, 284t
 Dicrotophos. *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 562t
 toxicity of, 292t
Dictamnus albus, 312t. *See also* plants, **309–319**
 Dicumarol
 in rodenticides, 378–380
 toxicity of, 378–380
 Dicyan (cyanogen), hazard summary for, 555t
 Dicyclomine. *See also* anticholinergic agents, **84–86**
 pharmacokinetics of, 386t
 toxicity of, 85t
 Didanosine. *See also* antiviral and antiretroviral agents, **111–115**
 pharmacokinetics of, 386t
 toxicity of, 112t
 Dieffenbachia (*Dieffenbachia* spp.), 313t. *See also* oxalic acid, **295–296**; plants, **309–319**
 calcium oxalate salt in, 295
 toxicity of, 313t
 Dieldrin. *See also* chlorinated hydrocarbons, **161–162**
 hazard summary for, 562t
 toxicity of, 161, 161t
 Di(2,3-epoxypropyl)-ether (diglycidyl ether), hazard summary for, 563t
 Diesel exhaust, hazard summary for, 562t
 Dietary supplements. *See also* herbal and alternative products, **215–218**
 toxicity of, 214
 caffeine and, 143
 Diethylamine, hazard summary for, 563t
 2-Diethylaminoethanol (DEAE), hazard summary for, 563t
 1,4-Diethylene dioxide (dioxane/1,4-dioxane). *See also* glycols, **194–198**
 hazard summary for, 566t
 toxicity of, 196t
 Diethylene glycol. *See also* glycols, **194–198**
 toxicity of, 195t, 197
 Diethylene oxide (tetrahydrofuran), hazard summary for, 618t
 Diethylenetriamine (DETA), hazard summary for, 563t
 Diethylenetriaminedipentaacetic acid (Zn-DTPA/Ca-DTPA), **439–440**
 pharmacology/use of, **439–440**
 for radiation poisoning, 330t, 439–440
 Diethyl ether (ethyl ether)
 hazard summary for, 571t
 osmolar gap elevation caused by, 32t
O,O-Diethyl-S-ethylmercapto-ethyl dithiophosphate (disulfoton). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 567t
 toxicity of, 292t
O,O-Diethyl S-(ethylthio)methyl phosphorodithioate (phorate). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 603t
 toxicity of, 292t
O-O-Diethyl *O*-2-isopropyl-4-methyl-6-pyrimidinylthiophosphate (diazinon). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 557t
 pralidoxime (2-PAM)/oximes for poisoning with, 492–494
 toxicity of, 292t
 Diethyl ketone, hazard summary for, 563t
 Diethyl mercaptosuccinate, *O,O*-dimethyl dithiophosphate of (malathion). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 585t
 pralidoxime (2-PAM)/oximes for poisoning with, 492–494
 toxicity of, 292t
 Diethyl mercury, hazard summary for, 586t
O,O-Diethyl *O*-[4-(methyl-sulfinyl)phenyl]phosphorothioate (tensulfothion). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 573t
 toxicity of, 292t
O,O-Diethyl *O*-*p*-nitrophenyl phosphorothioate (parathion). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 600t
 methyl, hazard summary for, 593t
 pralidoxime (2-PAM)/oximes for poisoning with, 492–494
 toxicity of, 292t
 Diethylpropion, 72, 73t. *See also* amphetamines, **72–74**
 pharmacokinetics of, 387t
 toxicity of, 72, 73t
 Diethylstilbestrol (DES)
 as antineoplastic agent. *See also* antineoplastic agents, **100–107**
 toxicity of, 103t
 teratogenic effects of, 59t
 Diethyl sulfate, hazard summary for, 563t
N,N-Diethylthanolamine (2-diethylaminoethanol/DEAE), hazard summary for, 563t
 Diethyltoluamide (DEET), seizures caused by, 23t
O,O-Diethyl-*O*-(3,5,6)-trichloro-2-pyridinyl (chlorpyrifos). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 551t
 toxicity of, 292t
 Difenacoum. *See also* warfarin, **378–380**
 in rodenticides, 378–380
 toxicity of, 378–380
 Difenoxin, with atropine (Motofen), 246–247
 Diflunisal. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
 pharmacokinetics of, 387t
 toxicity of, 284, 284t, 285

- Difluorodibromomethane (Freon 12B2), hazard summary for, 563t
- Difolatan (captafol), hazard summary for, 546
- Digibind. *See* digoxin-specific antibodies, 157, **434–436**
- Digitalis (cardiac) glycosides, **155–157**
- atrioventricular (AV) block caused by, 10t, 156
- bradycardia caused by, 10t, 156
- digoxin-specific antibodies for overdose of, 157, 434–436, 436t
- hyperkalemia caused by, 38, 38t, 156
- pharmacokinetics of, 156
- QRS interval prolongation caused by, 11t
- succinylcholine use and, 5
- toxicity of, **155–157**
- ventricular arrhythmias caused by, 14t, 156
- Digitalis purpurea* (foxglove), 155, 156, 313t. *See also* cardiac (digitalis) glycosides, **155–157**; plants, **309–319**
- Digitoxin, 155–157
- binding agent for, 53t
- digoxin-specific antibodies for overdose of, 157, 434–436, 436t
- elimination of, 56t, 156
- pharmacokinetics of, 156, 387t
- repeat-dose activated charcoal for overdose of, 58t
- toxicity of, 155–157
- volume of distribution of, 56t, 156, 387t
- Diglycidyl ether (DGE), hazard summary for, 563t
- Digoxin, 155–157
- digoxin-specific antibodies for overdose of, 157, 434–436, 436t
- elimination of, 56t, 156
- pharmacokinetics of, 156, 387t
- quantitative levels/potential interventions and, 45t
- toxicity of, 155–157
- in toxicology screens, interferences and, 43t
- volume of distribution of, 55t, 56t, 156, 387t
- Digoxin-specific antibodies, Fab fragments of, for cardiac glycoside toxicity, 157, **434–436**, 436t
- 2,3-Dihydro-2,2'-dimethyl-7-benzofuran-1-methylcarbamate (carbofuran). *See also* organophosphates and carbamates, **291–295**
- hazard summary for, 546t
- toxicity of, 293t
- Dihydroepiandrosterone (DHEA), 216t. *See also* herbal and alternative products, **215–218**
- Dihydroergocornine, toxicity of, 189–190
- Dihydroergocristine, toxicity of, 189–190
- Dihydroergocryptine, toxicity of, 189–190
- Dihydroergotamine (DHE-45)
- pharmacokinetics of, 387t
- toxicity of, 189–190
- 4,9-Dihydro-7-methoxy-1-methyl-3-pyrido-(3,4)-indole (harmaline), 248t, 314t. *See also* hallucinogens, **247–249**; plants, **309–319**
- 1,3-Dihydroxybenzene (resorcinol). *See also* phenols, **302–303**
- hazard summary for, 609t
- 1,4-Dihydroxybenzene (hydroquinone). *See also* phenols, **302–303**
- hazard summary for, 580t
- toxicity of, 302
- Diisobutyl ketone, hazard summary for, 564t
- Diisopropylamine, hazard summary for, 564t
- Diisopropyl ether (isopropyl ether), hazard summary for, 583t
- 2,6-Diisopropylphenol (propofol), **494–496**
- pharmacology/use of, **494–496**
- for seizures, 24, 494–496
- Dilacor. *See* diltiazem, 144, 145t
- Dilantin. *See also* phenytoin, **303–305**, **488–489**
- pharmacology/use of, 488–489
- toxicity of, 303–305
- Dilaudid. *See* hydromorphone, 289t
- Diltiazem. *See also* calcium antagonists, **144–147**
- hypotension caused by, 16t
- pharmacokinetics of, 387t
- toxicity of, 144, 145t

- Dimaval. *See* unithiol, **506–508**
- Dimenhydrinate. *See also* antihistamines, **96–98**
- pharmacokinetics of, 387t
- toxicity of, 97t
- Dimercaprol (BAL/dimercaptopropanol), **413–415**
- for arsenic poisoning, 118, 413–415
- for arsine gas poisoning, 120–121, 413–415
- for copper poisoning, 176
- for lead poisoning, 241, 413–415
- for mercury poisoning, 256–257, 413–415
- for methyl bromide poisoning, 265
- pharmacology/use of, **413–415**
- for thallium poisoning, 353
- for vesicant exposures, 377
- 2,3-Dimercaptopropanol-sulfonic acid (DMPS/unithiol), **506–508**
- for arsenic poisoning, 118, 506–508
- for arsine gas poisoning, 121
- for lead poisoning, 241, 506–508
- for mercury poisoning, 256, 506–508
- pharmacology/use of, **506–508**
- 2,3-Dimercaptosuccinate, sodium, 503. *See also* 2,3-Dimercaptosuccinic acid (succimer/DMSA), **501–503**
- 2,3-Dimercaptosuccinic acid (succimer/DMSA), **501–503**
- for arsenic poisoning, 118, 501–503
- for arsine gas poisoning, 121
- for lead poisoning, 241, 501–503
- for mercury poisoning, 256, 257, 501–503
- pharmacology/use of, **501–503**
- Dimetane. *See* brompheniramine, 97t
- Dimetapp Elixir. *See*
- brompheniramine, 97t
- phenylpropanolamine, **320–322**
- Dimethindene. *See also* antihistamines, **96–98**
- toxicity of, 97t
- Dimethoate. *See also* organophosphates and carbamates, **291–295**
- toxicity of, 292t
- 2,5-Dimethoxy-4-bromoamphetamine (DOB), 73, 248t. *See also* amphetamines, **72–74**; hallucinogens, **247–249**
- toxicity of, 73, 248t, 249
- Dimethoxy-DDT (methoxychlor). *See also* chlorinated hydrocarbons, **161–162**
- hazard summary for, 587t
- toxicity of, 161t
- Dimethoxymethane (methylal), hazard summary for, 588t
- 2,5-Dimethoxy-4-methyl-amphetamine (DOM/STP), 248t. *See also* hallucinogens, **247–249**
- toxicity of, 248t, 249
- Dimethrin. *See also* pyrethrins/pyrethroids, **322–324**
- toxicity of, 323t
- Dimethyl acetamide (DMAC)
- hazard summary for, 564t
- hepatotoxicity of, 524
- Dimethylamine (DMA), hazard summary for, 564t
- Dimethylaminopropionitrile, neuropathy caused by, 31t
- Dimethylaniline (xylydine), hazard summary for, 627t
- N,N*-Dimethylaniline, hazard summary for, 564t
- Dimethylbenzene (xylene), **357–359**
- exposure limits for, 358, 627t
- hazard summary for, 627t
- toxicity of, **357–359**
- 3,3'-Dimethylbenzidine (tolidene), hazard summary for, 620t
- 1,1'-Dimethyl-4,4'-bipyridinium dichloride (paraquat), **296–298**. *See also* caustic and corrosive agents, **157–159**
- binding agent for, 53t
- elimination of, 56t, 297
- hazard summary for, 600t
- hypoxia caused by, 7t
- oxygen therapy contraindications and, 298, 483
- pharmacokinetics of, 297
- toxicity of, 158t, **296–298**
- volume of distribution of, 56t, 297
- 2,3-Dimethyl-butane (hexane isomer), hazard summary for, 578t
- 1,3-Dimethylbutyl acetate (*sec*-hexyl acetate), hazard summary for, 578t
- Dimethylcarbamoyl chloride, hazard summary for, 564t

- Dimethyl *cis*-2-dimethylcarbamoyl-1-methylvinyl phosphate (dicrotophos). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 562*t*
toxicity of, 292*t*
- Dimethyldithiocarbamate, ferric (ferbam), hazard summary for, 574*t*
- O,O*-Dimethyl dithiophosphate of diethyl mercaptosuccinate (malathion). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 585*t*
pralidoxime (2-PAM)/oximes for poisoning with, 492–494
toxicity of, 292*t*
- O,O*-Dimethyl 2-ethylmercaptoethyl thiophosphate (methyl demeton), hazard summary for, 590*t*
- Dimethylformamide/*N,N*-dimethylformamide (DMF)
hazard summary for, 564–565*t*
hepatic failure caused by, 40*t*, 524
job processes associated with exposure to, 521*t*
- 2,6-Dimethyl-4-heptanone (diisobutyl ketone), hazard summary for, 564*t*
- 1,1-Dimethylhydrazine (DMH/UDMH), hazard summary for, 565*t*
- Dimethyl ketone (acetone)
drugs or toxins causing odor of, 32*t*
isopropyl alcohol, 32*t*, 235
estimation of level of from osmolar gap, 33*t*
hazard summary for, 533*t*
osmolar gap elevation caused by, 32*t*
in toxicology screens, 41*t*
- Dimethylmercury
hazard summary for, 565*t*
toxicity of, 255
- Dimethyl 2-methylcarbamoyl-1-methylvinyl phosphate (monocrotophos). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 595*t*
toxicity of, 292*t*
- O,O*-Dimethyl *O*-(3-methyl-4-[methylthio]phenyl)phosphorothioate (fenthion). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 574*t*
pralidoxime (2-PAM)/oximes for poisoning with, 492–494
toxicity of, 292*t*
- O,O*-Dimethyl *O*-*p*-nitro-phenylphosphorothioate (methyl parathion), hazard summary for, 593*t*
- Dimethylnitrosamine (*N*-nitrosodimethylamine), hazard summary for, 598*t*
- Dimethyl sulfate, hazard summary for, 565*t*
- Dimethyl sulfoxide (DMSO)
for antineoplastic infusion extravasation, 106
osmolar gap elevation caused by, 32*t*
- O,O*-Dimethyl-*O*-(2,4,5-trichlorophenyl)phosphorothioate (ronnel), hazard summary for, 610*t*
- N,N*-Dimethyltryptamine (DMT), 248*t*. *See also* hallucinogens, **247–249**
toxicity of, 248*t*
- Dimetilan. *See also* organophosphates and carbamates, **291–295**
toxicity of, 293*t*
- Dinitrobenzene, hazard summary for, 565*t*
- Dinitrobutylphenol (dinitrophenol/2,4-dinitrophenol), **298–300**
hazard summary for, 566*t*
hyperthermia caused by, 21*t*
occupational exposure to, 524
toxicity of, **298–300**
- Dinitro-*o*-cresol, hazard summary for, 565*t*
- Dinitrophenol/2,4-dinitrophenol, **298–300**
hazard summary for, 566*t*
hyperthermia caused by, 21*t*
occupational exposure to, 524
toxicity of, **298–300**
- 2-methyl-4,6-Dinitrophenol (dinitro-*o*-cresol), hazard summary for, 565*t*
- Dinitropropane, hepatotoxicity of, 524
- 2,4-Dinitrotoluene (DNT), hazard summary for, 566*t*
- Dinophysistoxins, diarrhetic shellfish poisoning caused by, 205–207
- Dinoseb (dinitrophenol/2,4-dinitrophenol), **298–300**
hazard summary for, 566*t*
hyperthermia caused by, 21*t*
occupational exposure to, 524
toxicity of, **298–300**
- Dioxane/1,4-dioxane. *See also* glycols, **194–198**
hazard summary for, 566*t*
toxicity of, 196*t*
- Dioxathion (2,3-*p*-dioxanedithiol *S,S*-bis [*O,O*-diethyl phosphorodithioate]), hazard summary for, 566*t*
- Dioxins, toxicity of, **184–186**
- Diphacinone. *See also* warfarin, **378–380**
in rodenticides, 378–380
toxicity of, 378–380
- Diphenhydramine, **436–437**. *See also* antihistamines, **96–98**
for anaphylactic/anaphylactoid reactions, 28
for antipsychotic-drug side effects/overdose, 109, 436–437
antivenom pretreatment and, 408, 436–437
in drug-assisted assault, 64*t*
for dystonia, 26, 109
pharmacokinetics of, 96, 387*t*
pharmacology/use of, **436–437**
QRS interval prolongation caused by, 11*t*
for scombroid shellfish poisoning, 207, 436–437
seizures caused by, 23*t*
toxicity of, 97*t*, 98, 437
in toxicology screens, 41*t*
- Diphenoxylate
with atropine (Lomotil/Lonox), **246–247**
toxicity of, **246–247**
in children, 60*t*, 246
pharmacokinetics of, 387*t*
- Diphenyl (biphenyl), hazard summary for, 540*t*
- Diphenylaminearsine (DM)
as chemical weapon, 375*t*. *See also* warfare agents, chemical, **372–378**
toxicity of, 375*t*
- Diphenyl benzenes (terphenyls), hazard summary for, 616*t*
- Diphenyl ether (phenyl ether), hazard summary for, 602*t*
- 4,4-Di-phenylmethane diisocyanate (methylene bisphenyl isocyanate), hazard summary for, 590*t*
- Diphenyl oxide, chlorinated, hazard summary for, 548*t*
- Diphenylpyraline. *See also* antihistamines, **96–98**
toxicity of, 97*t*
- Diprivan. *See* propofol, **494–496**
- Dipropylene glycol. *See also* glycols, **194–198**
toxicity of, 195*t*, 197
- Dipropylene glycol methyl ether (DPGME), hazard summary for, 566*t*
- Dipteryx odorata*, 317*t*. *See also* plants, **309–319**
- Dipyridyl herbicides. *See* paraquat and diquat, **296–298**
- Diquat, **296–298**
coma caused by, 19*t*
hazard summary for, 567*t*
pharmacokinetics of, 297
stupor caused by, 19*t*
toxicity of, **296–298**
- Direct-current countershock
for ventricular fibrillation, 15
for ventricular tachycardia without pulse, 15
- “Dirty bomb.” *See also* radiation, ionizing, **327–331**
radioactive materials in, 327
- Dishwashing liquid soap. *See also* low-toxicity products, **286**
accidental exposure to, 287*t*
- Disinfectants/antiseptics, **109–111**
- Disopyramide, **324–326**, 324*t*
atrioventricular (AV) block caused by, 10*t*
bradycardia caused by, 10*t*, 325
hypotension caused by, 16*t*
hypoxia caused by, 7*t*
pharmacokinetics of, 387*t*
QRS interval prolongation caused by, 11*t*, 325
toxicity of, **324–326**, 324*t*
ventricular arrhythmias caused by, 14*t*, 325
- Dispholidus envenomation*, 343*t*. *See also* snakebites, **343–346**

- Disposable diapers. *See also* nontoxic products, **286**
accidental exposure to, 287*t*
- Distribution, volume of (Vd), accessibility to removal by enhanced elimination and, 54, 55*t*, 56*t*
- Disulfiram, **186–187**
carbon disulfide as metabolite of, 150, 186
atherosclerotic disease and, 523
chemical coexposures and, 524
coma caused by, 19*t*, 186
confusion caused by, 24*t*, 186
delirium caused by, 24*t*
ethanol interaction and, 186, 187, 445
hazard summary for, 567*t*
mushroom intoxication and, 272*t*
neuropathy caused by, 31*t*
pharmacokinetics of, 186, 387*t*
stupor caused by, 19*t*, 186
teratogenic effects of, 59*t*
toxicity of, **186–187**
warfarin interaction and, 379*t*
- Disulfoton (*O,O*-diethyl-S-ethylmercapto-ethyl dithiophosphate). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 567*t*
toxicity of, 292*t*
- Disulfur decafluoride (sulfur pentafluoride), hazard summary for, 615*t*
- Dithiophosphate, *O,O*-diethyl-S-ethylmercapto-ethyl (disulfoton). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 567*t*
toxicity of, 292*t*
- Ditropan. *See* oxybutynin, 85*t*
- Diucardin. *See* hydroflumethiazide, 188*t*
- Diuresis
forced, for enhanced elimination, 55
in barium poisoning, 127
osmotic, for arsine gas poisoning, 120
- Diuretics, **187–189**, 188*t*
hypokalemia caused by, 38*t*, 39, 188
for hyponatremia, 37
hyponatremia caused by, 36*t*
thiazide
hyperglycemia caused by, 35*t*, 188
toxicity of, 188*t*
toxicity of, **187–189**, 188*t*
- Diuril. *See* chlorothiazide, 188*t*
- Divalproex sodium (Depakote). *See* valproic acid, |
362–364
- Divinylbenzene (DVB), hazard summary for, 567*t*
- DM (diphenylaminearsine)
as chemical weapon, 375*t*. *See also* warfare agents, chemical, **372–378**
toxicity of, 375*t*
- DMA (dimethylamine), hazard summary for, 564*t*
- DMAC (dimethyl acetamide)
hazard summary for, 564*t*
hepatotoxicity of, 524
- DMF (dimethylformamide/*N,N*-dimethylformamide)
hazard summary for, 564–565*t*
hepatic failure caused by, 40*t*, 524
job processes associated with exposure to, 521*t*
- DMH (1,1-dimethylhydrazine), hazard summary for, 565*t*
- DMPS (unithiol/2,3-dimercaptopropanol-sulfonic acid), **506–508**
for arsenic poisoning, 118, 506–508
for arsine gas poisoning, 121
for lead poisoning, 241, 506–508
for mercury poisoning, 256, 506–508
pharmacology/use of, **506–508**
- DMSA (succimer/meso-2,3-dimercaptosuccinic acid), **501–503**
for arsenic poisoning, 118, 501–503
for arsine gas poisoning, 121
for lead poisoning, 241, 501–503
for mercury poisoning, 256, 257, 501–503
pharmacology/use of, **501–503**
- DMSO (dimethyl sulfoxide)
for antineoplastic infusion extravasation, 106
osmolar gap elevation caused by, 32*t*
- DMT (*N,N*-dimethyltryptamine), 248*t*. *See also* hallucinogens, **247–249**
toxicity of, 248*t*
- DNP (dinitrophenol/2,4-dinitrophenol), **298–300**
hazard summary for, 566*t*
hyperthermia caused by, 21*t*
occupational exposure to, 524
toxicity of, **298–300**
- DNT (2,4-dinitrotoluene), hazard summary for, 566*t*
- DOB (2,5-dimethoxy-4-bromoamphetamine), 73, 248*t*, 249.
See also amphetamines, **72–74**; hallucinogens, **247–249**
toxicity of, 73, 248*t*, 249
- Docetaxel. *See also* antineoplastic agents, **100–107**
toxicity of, 103*t*
- Dofetilide, ventricular arrhythmias caused by, 14*t*
- Dogbane, 313*t*. *See also* plants, **309–319**
- Dogwood, 313*t*. *See also* plants, **309–319**
- Dolasetron, ventricular arrhythmias caused by, 14*t*
- Dolls-eyes, 313*t*. *See also* plants, **309–319**
- Dolobid. *See* diflunisal, 284, 284*t*, 285
- Dolophine. *See* methadone, 289*t*
- DOM (2,5-dimethoxy-4-methyl-amphetamine/STP), 248*t*.
See also hallucinogens, **247–249**
toxicity of, 248*t*, 249
- Domoic acid, food poisoning caused by (amnesic shellfish poisoning), 205–207, 206*t*

 toxicity of, 196*t*
- EGDN (ethylene glycol dinitrate), hazard summary for, 571*t*
- EGEE (ethylene glycol monoethyl ether/2-ethoxyethanol/ethyl cellosolve). *See also* glycols, **194–198**
 hazard summary for, 569*t*
 toxicity of, 196*t*
- Eggplant, 313*t*. *See also* plants, **309–319**
- Egg white, as binding agent, 53*t*
- EGME (ethylene glycol monomethyl ether/2-methoxyethanol/methyl cellosolve). *See also* glycols, **194–198**
 hazard summary for, 587*t*
 hematologic disorders caused by, 524
 toxicity of, 196*t*

- Elapidae envenomation, 343*t*, 344, 345. *See also* snakebites, **343–346**
- Elavil. *See* amitriptyline, 88*t*, 90
- Eldepryl. *See* selegiline, 269–271
- Elder, box, 311*t*. *See also* plants, **309–319**
- Elderberry, 313*t*. *See also* plants, **309–319**
- Electric dishwasher soap. *See also* detergents, **181–183**
- toxicity of, 182
- Electrocardiography (ECG), in circulatory function assessment, 9
- Electromagnetic radiation, ionizing, 327, 331. *See also* radiation, ionizing, **327–331**
- Elephant's ear, 313*t*. *See also* plants, **309–319**
- Elimination of drugs and toxins
- in emergency evaluation/treatment, 3*f*, **54–57**, 58*t*
- in neonates, 62
- Elixophyllin. *See* theophylline, **354–356**
- Elm, Chinese, 313*t*. *See also* plants, **309–319**
- Elspar. *See* asparaginase, 105*t*
- Emcyt. *See* estramustine, 103*t*
- Emergency evaluation and treatment, **1–65**, 2–3*f*
- airway and, **1–6**, 2*f*, 4*f*, 5*f*
- altered mental status and, 2–3*f*, **19–25**
- breathing and, **6–9**, 6*t*, 7*t*, 9*t*
- checklist of procedures for, 2–3*f*
- circulation and, 2*f*, **9–18**
- decontamination procedures in, 3*f*, **46–54**
- diagnosis/identification of substance in, 3*f*, **28–45**, 46*t*
- drug-facilitated assault and, **63–65**
- enhanced elimination in, 3*f*, **54–57**, 58*t*
- miscellaneous complications and, 3*f*, **25–28**
- patient disposition and, 3*f*, **58–59**
- in pediatric patient, **59–63**
- in pregnant patient, 58–59
- Emergency Response Planning Guidelines (ERPGs), 529
- Emery, hazard summary for, 567*t*
- Emesis
- blue-green
- in boric acid poisoning, 135–136
- in copper poisoning, 176
- for gastrointestinal decontamination, 48–49
- apomorphine use and, 411–412
- ipecac syrup for, 48–49, 228, 457–458
- in pregnant patient, 59
- Emetine (in ipecac syrup), 228, 229, 457
- EMLA Cream. *See*
- anesthetics, local, **74–77**
- lidocaine, 74, 75*t*, 76, **462–463**
- prilocaine, 75, 75*t*, 76
- Empirin. *See* aspirin, 331–333
- Enalapril. *See also* angiotensin blockers/ACE inhibitors, **77–78**
- pharmacokinetics of, 387*t*
- toxicity of, 77
- Encainide. *See also* antiarrhythmic drugs, **78–81**
- atrioventricular (AV) block caused by, 10*t*
- bradycardia caused by, 10*t*
- hypotension caused by, 16*t*
- pharmacokinetics of, 387*t*
- QRS interval prolongation caused by, 11*t*
- toxicity of, 79*t*, 80
- Encephalopathy, lead, 239, 241
- Endocrine disorders, hypoglycemia in, 35*t*
- Endoscopy, in caustic and corrosive agent injuries, 158, 159
- Endosulfan. *See also* chlorinated hydrocarbons, **161–162**
- hazard summary for, 567*t*
- toxicity of, 161, 161*t*
- Endotracheal intubation, **4–6**, 5*f*
- nasotracheal route for, 5, 5*f*
- orotracheal route for, 5–6, 5*f*
- neuromuscular blockers for, 5–6, 472–475
- for ventilatory failure, 7
- Endrin. *See also* chlorinated hydrocarbons, **161–162**
- hazard summary for, 568*t*
- toxicity of, 161, 161*t*
- English ivy, 313*t*. *See also* plants, **309–319**
- English laurel, 313*t*. *See also* plants, **309–319**
- Engraver's acid (nitric acid). *See also* gases, irritant, **213–215**
- exposure limits for, 214*t*, 596*t*
- hazard summary for, 596*t*
- toxicity of, 214*t*
- Enhanced elimination of drugs and toxins, in emergency evaluation/treatment, 3*f*, **54–57**, 58*t*
- Enliven. *See* 1,4-butanediol, 210–213, 211*t*
- Enolic acids. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
- coma and stupor caused by derivatives of, 19*t*
- toxicity of, 284*t*
- Enoxaparin, protamine for overdose of, 497–498
- Entactogens (hallucinogens), toxicity of, **247–249**, 248*t*
- Enteric-coated preparations, abdominal x-ray showing, 46*t*
- Enteroinvasive *Escherichia coli*, food poisoning caused by, 204*t*. *See also* food poisoning, bacterial, **203–205**
- Enterotohemorrhagic *Escherichia coli* (*E. coli* 0157:H7), food poisoning/systemic infection caused by, 203, 204*t*, 205. *See also* food poisoning, bacterial, **203–205**
- Enterotoxigenic *Escherichia coli*, food poisoning caused by, 204*t*. *See also* food poisoning, bacterial, **203–205**
- Enterotoxin B, staphylococcal, as biological weapon, 370*t*. *See also* warfare agents, biological, **367–372**
- Enteroviruses, food-borne gastroenteritis caused by, 203
- Envenomation
- insect, **225–226**
- anaphylactic reaction caused by, 28*t*, 226
- jellyfish (cnidarian), **236–237**
- lionfish (scorpaenidae), **242–243**
- scorpion for pain associated with, 468–469
- scorpion, **334–335**
- snake, **343–346**, 343*t*
- antivenoms for, 345, **407–409**, 408*t*, **410–411**
- hypotension caused by, 16*t*
- ventilatory failure caused by, 6*t*
- spider, **346–348**
- rigidity caused by, 26*t*, 347
- Environmental tobacco smoke, hazard summary for, 568*t*
- Environmental toxicology, **510–531**
- emergency medical response to hazardous materials incidents and, **510–518**
- exposure guidelines and, 528–530, 532–628*t*
- health hazard information and, 526–528, 532–628*t*
- patient evaluation in chemical exposure and, **518–526**
- Enzyme-containing detergents. *See also* detergents, **181–183**
- toxicity of, 182
- EPBP. *See also* organophosphates and carbamates, **291–295**
- toxicity of, 292*t*
- Ephedra/Ephedra spp, 217*t*, 218, 320. *See also* ephedrine, **320–322**; herbal and alternative products, **215–218**
- Ephedra viridis*, 315*t*. *See also* plants, **309–319**
- Ephedrine, **320–322**, 321*t*
- hypertension caused by, 18*t*, 321
- monoamine oxidase inhibitor interaction and, 270*t*, 320–321
- pharmacokinetics of, 320, 387*t*
- phenolamine for overdose of, 322, 487–488
- tachycardia caused by, 13*t*
- toxicity of, 217*t*, 218, **320–322**
- Epichlorohydrin, hazard summary for, 568*t*
- Epifoam. *See* pramoxine, 75*t*
- Epinephrine, **442–443**
- for allergic/anaphylactic/anaphylactoid reactions, 28, 442–443
- for beta-adrenergic blocker overdose, 133, 442–443
- for calcium antagonist overdose, 146, 442–443
- for chloroquine overdose, 167
- hyperglycemia caused by, 35*t*, 442
- hypertension caused by, 18*t*, 442
- hypokalemia caused by, 38*t*, 442
- with lidocaine. *See also* anesthetics, local, **74–77**
- toxicity of, 75*t*
- pharmacology/use of, **442–443**
- for ventricular fibrillation, 15
- Epipremnum aureum*, 313*t*, 316*t*. *See also* plants, **309–319**
- Epirubicin. *See also* antineoplastic agents, **100–107**
- toxicity of, 102*t*
- Epitol. *See* carbamazepine, **148–150**

- Epiriv. *See* lamivudine, 112*t*
- EPN (*O*-ethyl *O*-*p*-nitrophenyl phenylphosphonothioate). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 568*t*
toxicity of, 292*t*
- Epoxy glue, occupational exposure to, 521*t*
- 1,2-Epoxy-3-butoxy propane (*n*-butyl glycidyl ether), hazard summary for, 544*t*
- 1,2-Epoxy-3-phenoxypropane (phenyl glycidyl ether), hazard summary for, 602*t*
- 2-Epoxypropane (propylene oxide), hazard summary for, 608*t*
- 2,3-Epoxy-1-propanol (glycidol), hazard summary for, 576*t*
- Eprosartan, pharmacokinetics of, 387*t*
- Equagesic. *See*
aspirin, 331–333
meprobamate, 335*t*, 336
- Equanil. *See* meprobamate, 335*t*, 336
- Erasers. *See also* nontoxic products, **286**
accidental exposure to, 287*t*
- Erethism, in mercury poisoning, 355
- Ergamisol. *See* levamisole, 105*t*
- Ergoloid derivatives, toxicity of, 189–190
- Ergomar. *See* ergotamine, 189–190
- Ergonovine
pharmacokinetics of, 387*t*
toxicity of, 189–190
- Ergostat. *See* ergotamine, 189–190
- Ergotamine
pharmacokinetics of, 388*t*
toxicity of, 189–190
- Ergot derivatives, **189–190**
hypertension caused by, 18*t*
nitroprusside for overdose of, 190, 477–479
toxicity of, 189–190
- Ergotrate. *See* ergonovine, 189–190
- Ericaceae* family, 314*t*. *See also* plants, **309–319**
- Erigeron* sp., 313*t*. *See also* plants, **309–319**
- ERPGs (Emergency Response Planning Guidelines), 529
- Erythrina* spp., 312*t*. *See also* plants, **309–319**
- Erythromycin. *See also* antibacterial agents, **81–84**
pharmacokinetics of, 388*t*
toxicity of, 82*t*
ventricular arrhythmias caused by, 14*t*
- Escherichia coli*, food poisoning caused by, 203, 204*t*. *See also* food poisoning, bacterial, **203–205**
- Escherichia coli* O157:H7, food poisoning/systemic infection caused by, 203, 204*t*, 205. *See also* food poisoning, bacterial, **203–205**
- Eschscholzia californica*, 312*t*. *See also* plants, **309–319**
- Escitalopram, 88. *See also* antidepressants, noncyclic, **88–90**
toxicity of, 88
- Esgic. *See*
aspirin, 331–333
barbiturates (butalbital), **124–126**
caffeine, **142–144**
- Eskalith. *See* lithium, **243–246**
- Esmolol, 132*t*, **443–444**. *See also* beta-adrenergic blockers, **131–133**
for beta-agonist overdose, 135, 443–444
for caffeine poisoning, 144, 443–444
for carbon tetrachloride poisoning, 155
for chloroform poisoning, 155
for cocaine overdose, 173
for freon toxicity, 210
for hypertension, 18
for methylene chloride poisoning, 266
pharmacokinetics of, 388*t*
pharmacology/use of, **443–444**
for pseudoephedrine/ephedrine/decongestant-induced arrhythmias, 322
for sedative-hypnotic overdose, 336
for tachycardia, 13, 15
for theophylline overdose, 355, 443–444
for thyroid hormone overdose, 357
for toluene and xylene poisoning, 358
toxicity of, 132*t*, 444
for trichloroethane/trichloroethylene/perchloroethylene poisoning, 360
- Essential oils, toxicity of, **147–148**, 147*t*
- Estazolam. *See also* benzodiazepines, **129–131**, **415–418**
pharmacokinetics of, 388*t*
toxicity of, 130*t*
- Estramustine. *See also* antineoplastic agents, **100–107**
toxicity of, 103*t*
- Estrogens, as antineoplastic agents. *See also* antineoplastic agents, **100–107**
toxicity of, 103*t*
- Ethacrynic acid. *See also* diuretics, **187–189**
pharmacokinetics of, 388*t*
toxicity of, 188*t*
- Ethambutol. *See also* antibacterial agents, **81–84**
toxicity of, 82*t*
- Ethanedioic acid (oxalic acid), **295–296**. *See also* caustic and corrosive agents, **157–159**
calcium for poisoning caused by, 296, 424–426
exposure limits for, 295, 599*t*
hazard summary for, 599*t*
renal failure caused by, 39*t*
topical treatment for exposure to, 47*t*
toxicity of, 158*t*, **295–296**
- Ethanenitrile (acetonitrile). *See also* cyanide, **177–179**
hazard summary for, 533*t*
job processes associated with exposure to, 521*t*
toxicity of, 177
- Ethanthiol (ethyl mercaptan), hazard summary for, 573*t*
- Ethanol (ethyl alcohol), **190–193**, **444–446**, 446*t*
coma caused by, 19*t*, 191
disulfiram interaction and, 186, 187, 445
in drug-assisted assault, 64*t*
elimination of, 56*t*, 191
estimation of level of from osmolar gap, 33*t*, 192
for ethylene glycol poisoning, 198, 444–446, 446*t*
for formaldehyde poisoning, 208
hazard summary for, 570*t*
hepatic failure caused by, 40*t*, 191
hypoglycemia caused by, 35*t*, 191
hypothermia caused by, 20*t*, 192
for methanol poisoning, 261, 444–446, 446*t*
naloxone for overdose of, 192, 469–472
neuropathy caused by, 31*t*, 191
osmolar gap elevation caused by, 32*t*
pharmacokinetics of, 191
pharmacology/use of, **444–446**, 446*t*
poor adsorption to activated charcoal and, 52*t*
quantitative levels/potential interventions and, 45*t*, 192
rhabdomyolysis caused by, 27*t*, 191
stupor caused by, 19*t*, 191
teratogenic effects of, 59*t*
toxicity of, **190–193**, 445
in toxicology screens, 41*t*
“drugs of abuse” panel, 42*t*
interferences and, 43*t*
ventilatory failure caused by, 6*t*
volume of distribution of, 56*t*
withdrawal from, 192
confusion caused by, 24*t*
delirium caused by, 24*t*, 192
diazepam and lorazepam in management of, 192, 415–418
hypertension caused by, 18*t*
hyperthermia caused by, 21*t*
pentobarbital in management of, 485–486
phenobarbital in management of, 486–487
propofol in management of, 494–496
seizures caused by, 23*t*, 192
tachycardia caused by, 13*t*
- Ethanolamine (2-aminoethanol), hazard summary for, 568*t*
- Ethanolamines. *See also* antihistamines, **96–98**
toxicity of, 97*t*
- Ethchlorvynol. *See also* sedative-hypnotics, **335–337**
elimination of, 56*t*
hypoxia caused by, 7*t*
odor caused by, 32*t*
pharmacokinetics of, 388*t*
toxicity of, 335*t*, 336, 388*t*
in toxicology screens, 41*t*
volume of distribution of, 56*t*, 388*t*
- Ethenone (ketene), hazard summary for, 583*t*

- Ethers. *See also* hydrocarbons, **219–221**
 allyl glycidyl, hazard summary for, 535*t*
n-butyl glycidyl, hazard summary for, 544*t*
 bis(chloromethyl) (BCME), hazard summary for, 550*t*
 chloromethyl methyl (CMME), hazard summary for, 550*t*
 dichloroethyl (bis[2-chloroethyl]), hazard summary for, 561*t*
 diethyl (ethyl)
 hazard summary for, 571*t*
 osmolar gap elevation caused by, 32*t*
 diglycidyl (di-[2,3-epoxypropyl]), hazard summary for, 563*t*
 diisopropyl (isopropyl), hazard summary for, 583*t*
 diphenyl (phenyl), hazard summary for, 602*t*
 dipropylene glycol methyl (DPGME), hazard summary for, 566*t*
- ethyl
 hazard summary for, 571*t*
 osmolar gap elevation caused by, 32*t*
 ethylene glycol monobutyl (EGBE/2-butoxyethanol/butyl cellosolve). *See also* glycols, **194–198**
 hazard summary for, 542*t*
 toxicity of, 196*t*
 ethylene glycol monoethyl (EGEE/2-ethoxyethanol/ethyl cellosolve). *See also* glycols, **194–198**
 hazard summary for, 569*t*
 toxicity of, 196*t*
 ethylene glycol monoisopropyl (2-isopropoxyethanol), hazard summary for, 582*t*
 ethylene glycol monomethyl (EGME/2-methoxyethanol/methyl cellosolve). *See also* glycols, **194–198**
 hazard summary for, 587*t*
 hematologic disorders caused by, 524
 toxicity of, 196*t*
 isopropyl, hazard summary for, 583*t*
 isopropyl glycidyl, hazard summary for, 583*t*
 methyl tert butyl, hazard summary for, 594*t*
 petroleum. *See also* hydrocarbons, **219–221**
 hazard summary for, 601*t*
 toxicity of, 219, 219*t*
 phenyl (diphenyl), hazard summary for, 602*t*
 phenyl glycidyl, hazard summary for, 602*t*
 propylene glycol monomethyl, hazard summary for, 608*t*
 toxicity of, 219
- Ethiofencarb. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 293*t*
- Ethion. *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 569*t*
 toxicity of, 292*t*
- Ethmozine. *See* moricizine, 79*t*, 80
- Ethoprop. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
- Ethopropazine. *See also* antipsychotic drugs, **107–109**
 toxicity of, 107*t*
- 2-Ethoxyethanol (ethylene glycol monoethyl ether/EGEE/ethyl cellosolve). *See also* glycols, **194–198**
 hazard summary for, 569*t*
 toxicity of, 196*t*
- 2-Ethoxyethyl acetate, hazard summary for, 569*t*
- Ethyl acetate, hazard summary for, 569*t*
- Ethyl acrylate, hazard summary for, 569*t*
- Ethyl alcohol (ethanol), **190–193**, **444–446**, 446*t*
 coma caused by, 19*t*, 191
 disulfiram interaction and, 186, 187, 445
 in drug-assisted assault, 64*t*
 elimination of, 56*t*, 191
 estimation of level of from osmolar gap, 33*t*, 192
 for ethylene glycol poisoning, 198, 444–446, 446*t*
 for formaldehyde poisoning, 208
 hazard summary for, 570*t*
 hepatic failure caused by, 40*t*, 191
 hypoglycemia caused by, 35*t*, 191
 hypothermia caused by, 20*t*, 192
 for methanol poisoning, 261, 444–446, 446*t*
 naloxone for overdose of, 192, 469–472
 neuropathy caused by, 31*t*, 191
 osmolar gap elevation caused by, 32*t*
 pharmacokinetics of, 191
 pharmacology/use of, **444–446**, 446*t*
 poor adsorption to activated charcoal and, 52*t*
 quantitative levels/potential interventions and, 45*t*, 192
 rhabdomyolysis caused by, 27*t*, 191

 rhabdomyolysis caused by, 27*t*
 seizures caused by, 23*t*
 toxicity of, **194–198**
 in toxicology screens, interferences and, 43*t*
 treatment of poisoning caused by, 198
 bicarbonate for, 419–420
 ethanol for, 198, 444–446, 446*t*
 folic acid for, 198
 fomepizole for, 198, 445, 448–449
 poor adsorption to activated charcoal and, 52*t*
 pyridoxine for, 198, 499–500
 thiamine for, 198, 505
 volume of distribution of, 56*t*, 197, 198
- Ethylene glycol dinitrate (EGDN), hazard summary for, 571*t*

- Ethylene glycol monobutyl ether (EGBE/2-butoxyethanol/butyl cellosolve). *See also* glycols, **194–198**
hazard summary for, 542*t*
toxicity of, 196*t*
- Ethylene glycol monoethyl ether (EGEE/2-ethoxyethanol/ethyl cellosolve). *See also* glycols, **194–198**
hazard summary for, 569*t*
toxicity of, 196*t*
- Ethylene glycol monoethyl ether acetate (2-ethoxyethyl acetate), hazard summary for, 569*t*
- Ethylene glycol monoisopropyl ether (2-isopropoxyethanol), hazard summary for, 582*t*
- Ethylene glycol monomethyl ether (EGME/2-methoxyethanol/methyl cellosolve). *See also* glycols, **194–198**
hazard summary for, 587*t*
hematologic disorders caused by, 524
toxicity of, 196*t*
- Ethylene glycol monomethyl ether acetate (2-methoxyethyl acetate), hazard summary for, 587*t*
- Ethyleneimine, hazard summary for, 571*t*
- Ethylene oxide, **199–200**
exposure limits for, 199, 571*t*
hazard summary for, 571*t*
job processes associated with exposure to, 521*t*
reproductive disorders associated with use of, 199, 523
toxicity of, **199–200**
- Ethyl ether
hazard summary for, 571*t*
osmolar gap elevation caused by, 32*t*
- Ethyl formate, hazard summary for, 573*t*
- Ethylidene chloride (1,1-dichloroethane), hazard summary for, 560*t*
- Ethyl mercaptan, hazard summary for, 573*t*
- Ethylmercuric chloride. *See also* mercury, **254–257**
hazard summary for, 586*t*
- Ethylmercury. *See also* mercury, **254–257**
toxicity of, 256
- Ethyl 3-methyl-4-(methylthio)-phenyl(1-methylethyl)phosphoramidate (fenamiphos). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 573*t*
toxicity of, 292*t*
- O*-Ethyl *O*-(4-[methylthio]phenyl) *S*-propylphosphorodithioate (sulprofos). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 615*t*
toxicity of, 292*t*
- N*-Ethylmorpholine, hazard summary for, 573*t*
- Ethyl nitrite, toxicity of, 279–280
- O*-Ethyl-*O*-*p*-nitrophenyl phenylphosphonothioate (EPN). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 568*t*
toxicity of, 292*t*
- O*-Ethyl *S*-phenyl ethylphosphonothioate (fonofos). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 575*t*
toxicity of, 292*t*
- Ethyl silicate, hazard summary for, 573*t*
- Etidocaine. *See also* anesthetics, local, **74–77**
pharmacokinetics of, 388*t*
toxicity of, 75*t*
- Etodolac. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
pharmacokinetics of, 388*t*
toxicity of, 284*t*
- EtOH. *See* ethyl alcohol, **190–193; 444–446**
- Etoposide. *See also* antineoplastic agents, **100–107**
extravasation of, 106
toxicity of, 103*t*, 106
- Etrafon (amitriptyline with perphenazine). *See* amitriptyline, 88*t*, 90
perphenazine, 107*t*
- Etrifos. *See also* organophosphates and carbamates, **291–295**
toxicity of, 292*t*
- Eucalyptus (*Eucalyptus*)/eucalyptus oil. *See also* essential oils, **147–148**; plants, **309–319**
toxicity of, 147*t*, 313*t*
- Eugenol. *See also* essential oils, **147–148**; phenols, **302–303**
toxicity of, 147*t*, 302
- Eulexin. *See* flutamide, 103*t*
- Euonymus* spp, 312*t*, 317*t*. *See also* plants, **309–319**
- Eupatorium rugosum*, 317*t*. *See also* plants, **309–319**
- Euphorbiaceae, 310*t*. *See also* plants, **309–319**
- Euphorbia* spp, 312*t*, 316*t*. *See also* plants, **309–319**
- European beech, 311*t*. *See also* plants, **309–319**
- European hops, 314*t*. *See also* plants, **309–319**
- European mistletoe, 315*t*. *See also* plants, **309–319**
- Eutonyl. *See* pargyline, 269–271
- Eve (3,4-methylene-*n*-ethylamphetamine/MDE), 248*t*. *See also* amphetamines, **72–74**; hallucinogens, **247–249**
toxicity of, 248*t*
- Excedrin. *See* aspirin, 331–333
- Excedrin Extra Strength (ES). *See* acetaminophen, **66–69**
aspirin, 331–333
caffeine, **142–144**
- Excedrin Migraine. *See* acetaminophen, **66–69**
aspirin, 331–333
caffeine, **142–144**
- Excedrin PM. *See* acetaminophen, **66–69**
diphenhydramine, 97*t*, 98, **436–437**
- Exchange transfusion
for arsine gas poisoning, 120, 121
for iron poisoning, 231
for methemoglobinemia, 263
for nitrate/nitrite overdose, 280
- Exclusion Zone (hot or red zone), at hazardous materials incident site, 510, 511*f*
victim decontamination in, 515–516
victim stabilization in, 515
- Exemestane. *See also* antineoplastic agents, **100–107**
toxicity of, 103*t*
- Exercise, anaphylactic/anaphylactoid reaction caused by, 28*t*
- Exogonium purga*, 312*t*, 314*t*. *See also* plants, **309–319**
- Explosives work, toxic exposures and, 521*t*
- Exposure (environmental), hypothermia caused by, 20, 21
- Exposure guidelines, 528–530, 532–628*t*. *See also* specific substance
- Extended zinc insulin. *See also* insulin, 93–96, **455–456**
pharmacokinetics of, 391*t*
toxicity of, 94*t*
- Extrapyramidal symptoms, antipsychotic agents causing, 107*t*, 108
diphenhydramine for, 109, 436–437
- Extravasation
of antineoplastic agents, 106
thiosulfate for, 106, 505–506
of vasoconstrictive agents, phentolamine for, 487–488
- Eye makeup. *See also* nontoxic products, **286**
accidental exposure to, 287*t*
- Eyes
decontamination of, 47, 48*f*
examination of in diagnosis of poisoning, 30, 30*t*
Lewisite burns of, dimercaprol (BAL) for, 413–415
morphine for corrosive injury of, 468–469
- Fabric coating, toxic exposures and, 521*t*
- Fabric softeners. *See also* low-toxicity products, **286**
accidental exposure to, 287*t*
- Face masks, for oxygen therapy, 483
- Fagus crenta*, 311*t*. *See also* plants, **309–319**
- Fagus sylvatica*, 311*t*. *See also* plants, **309–319**
- False hellebore, 313*t*. *See also* plants, **309–319**
- False parsley, 313*t*. *See also* plants, **309–319**
- Famciclovir. *See also* antiviral and antiretroviral agents, **111–115**
pharmacokinetics of, 388*t*
toxicity of, 112*t*
- Famotidine. *See also* H₂ blockers, **428–430**
pharmacology/use of, 428–430, 430*t*

- Famphur. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
 “Fantasy” (slang). *See* gamma-hydroxybutyrate (GHB), 210–213, 211*t*
- Farmer’s lung, 522
- Fastin. *See* phentermine, 72, 73*t*
- Fasting, hypoglycemia caused by, 35*t*
- Fava beans, 313*t*. *See also* plants, **309–319**
 monoamine oxidase inhibitor interaction and, 270*t*
- Febrile inhalational syndromes, 520
- Felbamate. *See also* anticonvulsants, **86–87**
 pharmacokinetics of, 388*t*
 toxicity of, 86, 86*t*, 87
 ventricular arrhythmias caused by, 14*t*
- Felbatol. *See* felbamate, 86, 86*t*, 87
- Feldene. *See* piroxicam, 284, 284*t*, 285
- Felodipine. *See also* calcium antagonists, **144–147**
 pharmacokinetics of, 388*t*
 toxicity of, 144, 145*t*
- Felt-tip markers and pens. *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
- Fenamiphos. *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 573*t*
 toxicity of, 292*t*
- Fenchlorphos (ronnel), hazard summary for, 610*t*
- Fenfluramine, 72, 73*t*. *See also* amphetamines, **72–74**
 pharmacokinetics of, 388*t*
 toxicity of, 72, 73, 73*t*
 withdrawal of from market, 72
- Fenitrothion. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
- Fenocarb (BPMC). *See also* organophosphates and carbamates, **291–295**
 toxicity of, 293*t*
- Fenoldopam
 pharmacokinetics of, 388*t*
 toxicity of, 365–366
- Fenophosphon. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
- Fenopropfen. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
 pharmacokinetics of, 388*t*
 toxicity of, 284*t*, 285
- Fenothrin. *See also* pyrethrins/pyrethroids, **322–324**
 toxicity of, 323*t*
- “Fen-phen.” *See also* amphetamines, **72–74**
 toxicity of, 73
- Fensulfothion. *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 573*t*
 toxicity of, 292*t*
- Fentanyl, 289, 289*t*. *See also* opiates/opioids, **286–291**
 pharmacokinetics of, 289, 388*t*
 toxicity of, 289, 289*t*
- Fenthion. *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 574*t*
 pralidoxime (2-PAM)/oximes for poisoning with, 492–494
 toxicity of, 292*t*
- Fenvalerate. *See also* pyrethrins/pyrethroids, **322–324**
 toxicity of, 323*t*
- FeoSol. *See* iron, **230–232**
- FEP (free erythrocyte protoporphyrin), in lead poisoning, 240
- Ferbam, hazard summary for, 574*t*
- Fer-de-lance envenomation, 343*t*. *See also* snakebites, **343–346**
 Crotalidae/Crotalinae antivenom for, 345, 407–409
- Fer-In-Sol. *See* iron, **230–232**
- Ferric dimethyldithiocarbamate (ferbam), hazard summary for, 574*t*
- Ferric hexacyanoferrate (Prussian blue), **499**
 as binding agent, 53*t*, 330*t*
 pharmacology/use of, **499**
 for radiation poisoning, 330*t*, 499
 for thallium poisoning, 353, 499
- Ferrovanadium dust, hazard summary for, 574*t*
- Fertilizers. *See also* low-toxicity products, **286**
 accidental exposure to, 287*t*
- Feverfew, 216*t*. *See also* herbal and alternative products, **215–218**
- Fexofenadine. *See also* antihistamines, **96–98**
 pharmacokinetics of, 388*t*
 toxicity of, 97*t*
- Fibrillation, ventricular
 drugs and toxins causing, 14*t*
 hypothermia causing, 21
 treatment of, 15
 bretylum in, 421–422
 magnesium in, 463–464
- Fibrotic lung disease, occupational, 522
- Ficus (*Ficus benjamina*), 313*t*, 317*t*. *See also* plants, **309–319**
- Fingernail polish (dry). *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
- Finger sweep, for clearing airway, 1
- Floricet. *See*
 acetaminophen, **66–69**
 barbiturates (butalbital), **124–126**
 caffeine, **142–144**
- Florinal. *See*
 aspirin, 331–333
 barbiturates (butalbital), **124–126**
 caffeine, **142–144**
- Fipronil, seizures caused by, 23*t*
- Fire coral envenomation, 236–237
- Fire extinguishers. *See also* low-toxicity products, **286**
 accidental exposure to, 288*t*
- Fire fighting, toxic exposures and, 521*t*
- Fireplace ashes. *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
- Fireplace crystals. *See also* low-toxicity products, **286**
 accidental exposure to, 288*t*
- Firethorn, 313*t*. *See also* plants, **309–319**
- Firewater. *See* gamma-butyrolactone, 210–213, 211*t*
- Fish
 anaphylactic reaction caused by, 28*t*
 arsenobetaine and arsenocholine in, 117
 food poisoning caused by, **205–207**, 206*t*
- Flag, 313*t*. *See also* plants, **309–319**
- Flagyl. *See* metronidazole, 82*t*
- “Flashbacks,” with hallucinogen drug use, 247
- Flavoxate. *See also* anticholinergic agents, **84–86**
 pharmacokinetics of, 388*t*
 toxicity of, 85*t*
- Fleabane, 313*t*. *See also* plants, **309–319**
- Flea control products (topical). *See also* nontoxic products, **286**
 accidental exposure to, 288*t*
- Flecainide. *See also* antiarrhythmic drugs, **78–81**
 atrioventricular (AV) block caused by, 10*t*
 bradycardia caused by, 10*t*
 hypotension caused by, 16*t*
 pharmacokinetics of, 79, 388*t*
 QRS interval prolongation caused by, 11*t*
 toxicity of, 79*t*, 80
 ventricular arrhythmias caused by, 14*t*
- Flexeril. *See* cyclobenzaprine, 90, 340, 340*t*
- Floxuridine. *See also* antineoplastic agents, **100–107**
 toxicity of, 102*t*
- Fludara. *See* fludarabine, 102*t*
- Fludarabine. *See also* antineoplastic agents, **100–107**
 toxicity of, 102*t*
- Fluid loss, hypotension caused by, 16*t*
- Fluid/saline therapy
 for bromide poisoning, 141
 for hypernatremia, 36
 for hyponatremia, 37
 hyponatremia caused by, 36*t*
 for hypotension, 10, 16, 17
 in management of circulatory problems, 10
 for rhabdomyolysis, 27
- Flumazenil, 1, 336, 341, **446–447**
 for benzodiazepine-induced coma and stupor, 20, 131, 416, 446–447
 pharmacology/use of, **446–447**
 seizures caused by, 20, 131

- Flunarizine. *See also* antihistamines, **96–98**
toxicity of, *97t*
- Flunitrazepam. *See also* benzodiazepines, **129–131, 415–418**
in drug-assisted assault, *64*
pharmacokinetics of, *388t*
toxicity of, *130t*
- Fluorescent light bulbs. *See also* low-toxicity products, **286**
accidental exposure to, *288t*
- Fluoride, **200–201, 200t**
calcium for poisoning caused by, *201, 424–426*
hazard summary for, *574t*
hyperkalemia caused by, *38, 38t*
hypotension caused by, *16t*
pharmacokinetics of, *200, 388t*
poor adsorption to activated charcoal and, *52t*
seizures caused by, *23t*
toxicity of, **200–201**
ventricular arrhythmias caused by, *14t*
- Fluoride dust, hazard summary for, *574t*
- Fluorinated hydrocarbons (freons), **209–210**
exposure limits for, *209*
propranolol for poisoning caused by, *210, 496–497*
toxicity of, **209–210**
ventricular arrhythmias caused by, *14t, 209, 210, 526–527*
- Fluorine. *See also* gases, irritant, **213–215**
exposure limits for, *214t, 574t*
hazard summary for, *574t*
toxicity of, *214t*
- Fluorine monoxide (oxygen difluoride), hazard summary for, *600t*
- Fluoroacetamide (compound 1081). *See also* fluoroacetate, **201–202**
toxicity of, *201*
- Fluoroacetate (sodium fluoroacetate/compound 1080), **201–202**
hazard summary for, *612t*
pharmacokinetics of, *202*
toxicity of, **201–202**
- Fluorocarbon 12 (dichlorodifluoromethane/Freon 12)
hazard summary for, *559t*
toxicity of, *209–210*
- Fluorocarbon 21 (dichlorofluoromethane/Freon 21)
hazard summary for, *561t*
toxicity of, *209–210*
- Fluorocarbon 114 (dichlorotetrafluoroethane/Freon 114)
hazard summary for, *562t*
toxicity of, *209–210*
- Fluorocarbon 115 (chloropentafluoroethane), hazard summary for, *551t*
- Fluorocarbons (freons), **209–210**
exposure limits for, *209*
propranolol for poisoning caused by, *210, 496–497*
toxicity of, **209–210**
ventricular arrhythmias caused by, *14t, 209, 210, 526–527*
- 5-Fluorouracil. *See also* antineoplastic agents, **100–107**
teratogenic effects of, *59t*
toxicity of, *102t*
- Fluoxetine, *88*. *See also* antidepressants, noncyclic, **88–90**
monoamine oxidase inhibitor interaction and, *22, 89, 270*
pharmacokinetics of, *388t*
toxicity of, *88, 88t, 89*
ventricular arrhythmias caused by, *14t*
- Fluphenazine. *See also* antipsychotic drugs, **107–109**
pharmacokinetics of, *389t*
toxicity of, *107t*
- Flurazepam. *See also* benzodiazepines, **129–131, 415–418**
pharmacokinetics of, *389t*
toxicity of, *130t*
- Flushed red skin
in carbon monoxide poisoning, *152*
in diagnosis of poisoning, *31*
- Flutamide. *See also* antineoplastic agents, **100–107**
toxicity of, *103t*
- Fluvoxamine, *88*. *See also* antidepressants, noncyclic, **88–90**
monoamine oxidase inhibitor interaction and, *270t*
pharmacokinetics of, *389t*
toxicity of, *88, 88t, 89*
- Folate. *See* folic acid, **447–448**
- Foley catheter, in management of circulatory problems, *10*
- Folic acid, **447–448**
for ethylene glycol poisoning, *198*
for formaldehyde/formate poisoning, *208*
for methanol poisoning, *261, 447–448*
pharmacology/use of, **447–448**
- Folic acid antagonists, leucovorin calcium for overdose of, *460–461, 461t*
- Folinic acid (leucovorin calcium), **460–461, 461t**
for methanol poisoning, *261, 460–461*
pharmacology/use of, **460–461, 461t**
for trimethoprim poisoning, *81, 460–461*
- Folvite. *See* folic acid, **447–448**
- Fomepizole, **448–449**
for ethylene glycol poisoning, *198, 445, 448–449*
for methanol poisoning, *261, 445, 448–449*
pharmacology/use of, **448–449**
- Fonofos. *See also* organophosphates and carbamates, **291–295**
hazard summary for, *575t*
toxicity of, *292t*
- Food poisoning. *See also* mushroom poisoning, **271–275**
bacterial, **203–205, 204t**
botulism, **136–138**
botulin/botulinum antitoxin for, *138, 420–421*
fish and shellfish, **205–207, 206t**
- Foods
anaphylactic reaction caused by, *28t*
monoamine oxidase inhibitor interaction and, *270t*
- Fool's parsley, *313t*. *See also* plants, **309–319**

- Fosphenytoin, **488–489**. *See also* phenytoin, **488–489**
pharmacokinetics of, *389t*
pharmacology/use of, **488–489**
ventricular arrhythmias caused by, *14t*
- Four o'clock, *313t*. *See also* plants, **309–319**

- Foxglove, 155, 156, 313*t*. *See also* cardiac (digitalis) glycosides, **155–157**; plants, **309–319**
- Francisella tularensis* (tularemia), as biological weapon, 367, 369*t*, 371. *See also* warfare agents, biological, **367–372**
- Fraxinus* spp, 311*t*. *See also* plants, **309–319**
- "Free base" cocaine, 171. *See also* cocaine, 171–173
- Free erythrocyte protoporphyrin (FEP), in lead poisoning, 240
- Freon 11 (trichlorofluoromethane)
hazard summary for, 622*t*
toxicity of, 209–210
- Freon 12 (dichlorodifluoromethane)
hazard summary for, 559*t*
toxicity of, 209–210
- Freon 12B2 (difluorodibromomethane), hazard summary for, 563*t*
- Freon 13B1 (trifluorobromomethane), hazard summary for, 623*t*
- Freon 21 (dichlorofluoromethane)
hazard summary for, 561*t*
toxicity of, 209–210
- Freon 22 (chlorodifluoromethane)
hazard summary for, 550*t*
toxicity of, 209–210
- Freon 23 (trifluoromethane), hazard summary for, 623*t*
- Freon 113 (1,1,2-trichloro-1,2,2-trifluoroethane)
hazard summary for, 623*t*
toxicity of, 209–210
- Freon 114 (dichlorotetrafluoroethane)
hazard summary for, 562*t*
toxicity of, 209–210
- Freons (fluorinated hydrocarbons), **209–210**
exposure limits for, 209
propranolol for poisoning caused by, 210, 496–497
toxicity of, **209–210**
ventricular arrhythmias caused by, 14*t*, 209, 210, 526–527
- Frostbite, liquid sulfur dioxide causing, 350
- Fuller's earth, as binding agent, 53*t*
- Fulvestrant. *See also* antineoplastic agents, **100–107**
toxicity of, 103*t*
- Fumes, combustion, occupational exposure to, 519
- Fumigation, toxic exposures and, 521*t*
- Furadan (carbofuran). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 546*t*
toxicity of, 293*t*
- Furamethrin. *See also* pyrethrins/pyrethroids, **322–324**
toxicity of, 323*t*
- Furan. *See* gamma-butyrolactone, 210–213, 211*t*
- 2,5-Furandione (maleic anhydride), hazard summary for, 585*t*
- Furanone Extreme. *See* gamma-butyrolactone, 210–213, 211*t*
- Furazolidone. *See also* monoamine oxidase inhibitors, **269–271**
toxicity of, 269–271
- Furfural, hazard summary for, 575*t*
- Furfuryl alcohol, hazard summary for, 575*t*
- Furniture polish. *See also* hydrocarbons, **219–221**
toxicity of, 219
- Furniture refinishing, toxic exposures and, 521*t*
- Furomax. *See* gamma-butyrolactone, 210–213, 211*t*
- Furosemide. *See also* diuretics, **187–189**
for bromide poisoning, 141
for hyponatremia, 37
pharmacokinetics of, 389*t*
toxicity of, 188*t*
- Furoxone. *See* furazolidone, 269–271
- Fusarium* spp. *See also* molds, **267–269**
toxicity of, 267
- FX Cherry Bomb/Lemon Drop/Orange/Rush. *See* 1,4-butanediol, 210–213, 211*t*
- G3. *See* gamma-butyrolactone, 210–213, 211*t*
- GA (tabun). *See also* organophosphates and carbamates, **291–295**
as chemical weapon, 372, 373, 374*t*. *See also* warfare agents, chemical, **372–378**
oximes for poisoning with, 492–494
toxicity of, 372, 373, 374*t*
- Gabapentin. *See also* anticonvulsants, **86–87**
for ciguatera shellfish poisoning, 207
pharmacokinetics of, 389*t*
toxicity of, 86*t*, 87
- Gabitril. *See* tiagabine, 86*t*, 87
- Gaboon viper envenomation, 343*t*. *See also* snakebites, **343–346**
- Gag reflex, airway assessment and, 1
- Galerina autumnalis*, 272*t*, 273–275. *See also* mushroom poisoning, **271–275**
toxicity of, 272*t*, 273–275
- Galerina marginata*, 272*t*, 273–275. *See also* mushroom poisoning, **271–275**
- Galium odoratum*, 318*t*. *See also* plants, **309–319**
- Galvanized steel, welding, toxic exposures and, 521*t*
- Gamma-butyrolactone (GBL/GHB precursor), 210–213, 211*t*
pharmacokinetics of, 389*t*
- Gamma G. *See* gamma-butyrolactone, 210–213, 211*t*
- Gamma-hexachlorocyclohexane (lindane). *See also* chlorinated hydrocarbons, **161–162**
hazard summary for, 584*t*
toxicity of, 161, 161*t*
in children, 60*t*, 161
volume of distribution of, 55*t*
- Gamma Hydrate. *See* gamma-hydroxybutyrate (GHB), 210–213, 211*t*
- Gamma-hydroxybutyrate/gamma-hydroxybutyric acid (GHB), **210–213**, 211*t*
coma caused by, 19*t*, 212
in drug-assisted assault, 64*t*, 212
dyskinesias caused by, 26*t*
pharmacokinetics of, 212, 389*t*
seizures caused by, 23*t*, 212
stupor caused by, 19*t*, 212
toxicity of, **210–213**
ventilatory failure caused by, 6*t*
- Gamma OH. *See* gamma-hydroxybutyrate (GHB), **210–213**
- Gamma Ram. *See* gamma-butyrolactone, 210–213, 211*t*
- Ganciclovir. *See also* antiviral and antiretroviral agents, **111–115**
pharmacokinetics of, 389*t*
toxicity of, 112*t*, 114
- Garamycin. *See* gentamicin, 82*t*
- Garden sorrel, 313*t*. *See also* plants, **309–319**
- Garlic, 216*t*. *See also* herbal and alternative products, **215–218**
drugs or toxins causing odor of, 32*t*
selenium, 32*t*, 337, 338
- Gas emboli, hydrogen peroxide ingestion causing, 110, 111
- Gases. *See also* specific type
inert, hypoxia caused by, 7*t*
irritant, **213–215**, 214*t*
bronchospasm caused by, 9, 9*t*
exposure limits for, 214, 214*t*
hypoxia caused by, 7*t*, 8
occupational exposure to, 520
smoke inhalation and, 341, 342
toxicity of, **213–215**, 214*t*
- Gasoline. *See also* hydrocarbons, **219–221**
hazard summary for, 576*t*
toxicity of, 219, 219*t*
- Gasoline additive, (methylcyclopentadienyl manganese tricarbonyl/MMT), toxicity of, 251–252
- Gas-shielded welding, toxic exposures and, 521*t*
- Gas sterilizers, reproductive disorders associated with use of, 523
- Gastric contents, aspiration of, hypoxia caused by, 7*t*, 8
- Gastric lavage, for gastrointestinal decontamination, 49–50, 51*f*
in caustic and corrosive agent ingestion, 159
in pregnant patient, 59
toxic ingestions and, 516
- Gastroenteritis
in amatoxin-type mushroom poisoning, 272*t*, **273–275**
in bacterial food poisoning, **203–205**
in fish and shellfish food poisoning, **205–207**

- Gastroenteritis (*cont.*)
 hyponatremia caused by, 36*t*
 in mushroom poisoning, **271–275**, 272*t*
- Gastrointestinal system
 antineoplastic agent toxicity and, 106
 in arsenic poisoning, 116
 cancer of, asbestos exposure and, 122
 decontamination of, **47–54**
 activated charcoal for, 50–51, 52*t*
 cathartics for, 52
 emesis for, 48–49
 gastric lavage for, 49–50, 51*f*
 oral binding agents for, 53, 53*t*
 surgery for, 54
 whole bowel irrigation for, 52–53
 in lead poisoning, 239
 morphine for corrosive injury of, 468–469
 radiation exposure affecting, 328–329
- Gatifloxacin, ventricular arrhythmias caused by, 14*t*
- GB (Sarin). *See also* organophosphates and carbamates, **291–295**
 as chemical weapon, 372, 373, 374*t*. *See also* warfare agents, chemical, **372–378**
 pralidoxime (2-PAM)/oximes for poisoning with, 377, 492–494
 toxicity of, 372, 373, 374*t*
- GBL (gamma butyrolactone/GHB precursor), 210–213, 211*t*
 pharmacokinetics of, 389*t*
- “G caps” (slang). *See* gamma-hydroxybutyrate (GHB), 210–213, 211*t*
- G-CSF (granulocyte colony-stimulating factor), for colchicine overdose, 175
- GD (Soman). *See also* organophosphates and carbamates, **291–295**
 as chemical weapon, 372, 373, 374*t*. *See also* warfare agents, chemical, **372–378**
 pralidoxime (2-PAM)/oximes for poisoning with, 377, 492–494
 toxicity of, 372, 373, 374*t*
- Gelsemium indole alkaloids. *See also* plants, **309–319**
 toxicity of, 310*t*
- Gelsemium sempervirens*, 314*t*. *See also* plants, **309–319**
- Gemcitabine. *See also* antineoplastic agents, **100–107**
 toxicity of, 102*t*
- Gemfibrozil, rhabdomyolysis caused by, 27*t*
- Gentzumab ozogamicin. *See also* antineoplastic agents, **100–107**
 toxicity of, 104*t*
- Gengraf. *See* cyclosporin, 39*t*
- Gentamicin. *See also* antibacterial agents, **81–84**
 for biological warfare agents, 372
 pharmacokinetics of, 389*t*
 toxicity of, 82*t*
- GenX. *See* gamma-butyrolactone, 210–213, 211*t*
- Geocillin. *See* carbenicillin, 83*t*
- Geodon. *See* ziprasidone, 107*t*
- “Georgia Home Boy” (slang). *See* gamma-hydroxybutyrate (GHB), 210–213, 211*t*
- Geranium, 313*t*. *See also* plants, **309–319**
 California, 312*t*, 313*t*
- Germanium tetrahydride, hazard summary for, 576*t*
- GF. *See also* organophosphates and carbamates, **291–295**
 as chemical weapon, 372. *See also* warfare agents, chemical, **372–378**
 toxicity of, 372
- GHB (gamma-hydroxybutyrate), **210–213**, 211*t*
 coma caused by, 19*t*, 212
 in drug-assisted assault, 64*t*, 212
 dyskinesias caused by, 26*t*
 pharmacokinetics of, 212, 389*t*
 seizures caused by, 23*t*, 212
 stupor caused by, 19*t*, 212
 toxicity of, **210–213**
 ventilatory failure caused by, 6*t*
- GH Gold (GHG). *See* gamma-butyrolactone, 210–213, 211*t*
- GHRE (GH Releasing Extract). *See* 1,4-butanediol, 210–213, 211*t*
- GH Release. *See* gamma-butyrolactone, 210–213, 211*t*
- GH Releasing Extract (GHRE). *See* 1,4-butanediol, 210–213, 211*t*
- GH Relief. *See* gamma-butyrolactone, 210–213, 211*t*
- GH Revitalizer. *See* gamma-butyrolactone, 210–213, 211*t*
- Ginkgo (*Ginkgo biloba*), 216*t*, 313*t*. *See also* herbal and alternative products, **215–218**; plants, **309–319**
 warfarin interaction and, 379*t*
- Ginseng, 216*t*. *See also* herbal and alternative products, **215–218**
- Glacier ivy, 313*t*. *See also* plants, **309–319**
- Glassmaking, toxic exposures and, 521*t*
- Glecoma hederacea*, 312*t*. *See also* plants, **309–319**
- Gladel. *See* carmustine, 101*t*
- Glimepiride. *See also* antidiabetic (hypoglycemic) agents, **93–96**
 pharmacokinetics of, 389*t*
 toxicity of, 94*t*
- Glipizide. *See also* antidiabetic (hypoglycemic) agents, **93–96**
 pharmacokinetics of, 389*t*
 toxicity of, 93, 94*t*
- Glitazones. *See also* antidiabetic (hypoglycemic) agents, **93–96**
 pharmacokinetics of, 94*t*
 toxicity of, 93, 94*t*
- Glitter. *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
- Glomerular nephritis, occupational causes of, 524
- Gloriosa superba*, 173. *See also* colchicine, **171–173**
- Glory lily, 173. *See also* colchicine, **171–173**
- Glory pea, 313*t*. *See also* plants, **309–319**
- Glow stick/jewelry. *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
- Glucagon, **449–450**
 for beta-adrenergic blocker overdose, 133, 449–450
 for calcium antagonist overdose, 146, 449–450
 hyperglycemia caused by, 35*t*, 450
 pharmacology/use of, **449–450**
- Glucans. *See also* molds, **267–269**
 toxicity of, 267–268
- Glucophage. *See* metformin, 93, 94*t*, 96
- Glucosamine, 216*t*. *See also* herbal and alternative products, **215–218**
- Glucose, **450–451**
 for alcohol-related disorders, 192
 alterations in serum levels of, 34–35, 35*t*
 causes of, 35*t*
 for antidiabetic agent overdose, 95, 450–451
 for hyperthermia, 22
 for hypoglycemia, 95, 450–451
 with insulin, for calcium antagonist overdose/hyperkalemia, 38, 146, 450–451, 455–456
 pharmacology/use of, **450–451**
 in toxicology screens, interferences and, 43*t*
- Glucotrol. *See* glipizide, 93, 94*t*
- Glucovance. *See*
 glyburide, 93, 94*t*
 metformin, 93, 94*t*, 96
- Glue. *See also* low-toxicity products, **286**
 accidental exposure to, 287*t*, 288*t*
 two-part, occupational exposure to, 519
- Glutaraldehyde. *See also* antiseptics/disinfectants, **109–111**
 hazard summary for, 576*t*
 job processes associated with exposure to, 521*t*
 toxicity of, 109, 110
- Glutethimide. *See also* sedative-hypnotics, **335–337**
 elimination of, 56*t*
 mydriasis caused by, 30*t*
 pharmacokinetics of, 389*t*
 toxicity of, 335*t*, 336
 in toxicology screens, 41*t*
 volume of distribution of, 56*t*, 389*t*
 warfarin interaction and, 379*t*
- Glyburide. *See also* antidiabetic (hypoglycemic) agents, **93–96**
 pharmacokinetics of, 389*t*
 toxicity of, 93, 94*t*
- Glycerin. *See also* low-toxicity products, **286**
 accidental exposure to, 287*t*
- Glycerol trinitrate (nitroglycerin)
 contraindications to sildenafil use and, 279
 for ergot overdose, 190

- hazard summary for, 598t
toxicity of, 279–280
- Glyceryl monoacetate (monoacetin), in fluoroacetate poisoning, 202
- Glycidol, hazard summary for, 576t
- Glycidylbutylether (*n*-butyl glycidyl ether), hazard summary for, 544t
- Glycidyl ether
allyl, hazard summary for, 535t
isopropyl, hazard summary for, 583t
- Glycolate, renal failure caused by, 39t
- Glycolic acid, levels of in ethylene glycol poisoning, 197
- Glycols, **194–198**, 195–196t
estimation of level of from osmolar gap, 33t
osmolar gap elevation caused by, 32t
toxicity of, **194–198**
- Glycopyrrolate, 85t, **412–413**. *See also* anticholinergic agents, **84–86**
pharmacokinetics of, 389t
pharmacology/use of, **412–413**
toxicity of, 85t, 412–413
- Glycyrrhiza lepidota*, 314t. *See also* plants, **309–319**
- Glynnase. *See* glyburide, 93, 94t
- Golden chain, 313t. *See also* plants, **309–319**
- Goldenrod, 313t. *See also* plants, **309–319**
- Goldenseal, 217t, 313t. *See also* herbal and alternative products, **215–218**; plants, **309–319**
- Gold poisoning
acetylcysteine for, 405–407
dimercaprol (BAL) for, 413–415
- Gold refining, toxic exposures and, 521t
- Gonadotropin-releasing hormone analogs, as antineoplastic agents. *See also* antineoplastic agents, **100–107**
toxicity of, 103t
- Goodpasture's disease, occupational causes of, 524
- "Goon" (slang). *See* phenacyclidine, **300–302**
- Gordoloba (*Achillea millefolium*), 313t. *See also* plants, **309–319**
- Gordolobo (*Senecio* spp), 313t. *See also* plants, **309–319**
- Goserelin. *See also* antineoplastic agents, **100–107**
toxicity of, 103t
- Gotu kola, 313t. *See also* plants, **309–319**
- Grain alcohol. *See* ethyl alcohol, **190–193**; **444–446**
- Gramicidin. *See also* antibacterial agents, **81–84**
toxicity of, 82t
- Gramoxone Extra (paraquat 37%). *See* paraquat, 158t, **296–298**
- Gramoxone Max (paraquat 43.8%). *See* paraquat, 158t, **296–298**
- Granulocyte colony-stimulating factor (G-CSF), for colchicine overdose, 175
- Grape seed extract, 217t. *See also* herbal and alternative products, **215–218**
- "Grass" (slang). *See* marijuana, **252–254**
- Grayanotoxin. *See also* plants, **309–319**
toxicity of, 310t
- Green zone (Support Zone), at hazardous materials incident site, 510, 511f
- victim management in, 516
- Greta, 216t, 238. *See also* herbal and alternative products, **215–218**; lead, **238–242**
- "Grievous Bodily Harm" (slang). *See* gamma-hydroxybutyrate (GHB), 210–213, 211t
- "G-riffick" (slang). *See* gamma-hydroxybutyrate (GHB), 210–213, 211t
- Grindelia (*Grindelia* spp), 313t. *See also* plants, **309–319**
- Groundsel, 313t. *See also* plants, **309–319**
- Guaiac (*Guaiacum officinale*), 313t. *See also* plants, **309–319**
- Guaiacol. *See also* essential oils, **147–148**
toxicity of, 147t
- Guafenesin. *See also* low-toxicity products, **286**
accidental exposure to, 287t
- Guanabenz
pharmacokinetics of, 389t
toxicity of, 169–171
- Guanadine, for botulism, 138
- Guanethidine, monoamine oxidase inhibitor interaction and, 270t
- Guanfacine
pharmacokinetics of, 389t
toxicity of, 169–171
- Guarana (*Paulinia cupana*). *See also* herbal and alternative products, **215–218**
toxicity of, 143, 217t, 218
- Gum. *See also* nontoxic products, **286**
accidental exposure to, 287t
nicotine. *See also* nicotine, **277–278**
toxicity of, 277
- Gun bluing (selenious acid). *See also* selenium, **337–339**
toxicity of, 337–338, 338t
in children, 60t
- Guthion (azinphos-methyl). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 539t
toxicity of, 292t
- Gymnocladus dioica*, 314t. *See also* plants, **309–319**
- Gynergen. *See* ergotamine, 189–190
- Gynura segetum*, 317t. *See also* plants, **309–319**
- Gypsum. *See also* nontoxic products, **286**
accidental exposure to, 287t
- Gyrometra (Helvella) esculenta* mushrooms. *See also* mushroom poisoning, **271–275**
toxicity of, 272t
treatment of monomethylhydrazine poisoning caused by, 273
pyridoxine for, 273, 499–500
- H₁ receptor antagonists, **96–98**, 97t
- H₂ blockers, **428–430**, 430t
confusion caused by, 24t, 429
pharmacology/use of, **428–430**, 430t
- H₂SO₄ (sulfuric acid), hazard summary for, 614t
- HAART (highly active antiretroviral therapy), 111. *See also* antiviral and antiretroviral agents, **111–115**
- Habitrol. *See* nicotine, **277–278**
- Hafnium, hazard summary for, 576t
- Hair, arsenic concentrations in, 118
- Hair conditioners. *See also* low-toxicity products, **286**
accidental exposure to, 287t
- Hair jellyfish (*Cyanea capillata*) envenomation, treatment of, 237
- Hair shampoos. *See also* low-toxicity products, **286**
accidental exposure to, 287t
- Halane (1,3-dichloro-5,5-dimethylhydantoin), hazard summary for, 560t
- Halcion. *See* triazolam, 129, 130, 130t
- Haldol. *See* haloperidol, 107t, **451–453**
- Half life (*T*_{1/2}), effectiveness of enhanced elimination and, 55
- Halloween candy, poisoned/adulterated, 288t
- Hallucination. *See also* hallucinogens, **247–249**
mushrooms causing, 272t
- Hallucinogens
as chemical weapons, 373, 376, 377. *See also* warfare agents, chemical, **372–378**
toxicity of, **247–249**, 248t, 376
- Halocarbon 112 (1,1,2,2-tetrachloro-1,2-difluoroethane), hazard summary for, 617t
- Halocarbon 112a (1,1,1,2-tetrachloro-2,2-difluoroethane), hazard summary for, 616t
- Halofantrine, ventricular arrhythmias caused by, 14t
- Halogenated hydrocarbons. *See also* hydrocarbons, **219–221**
toxicity of, 219, 219t
hepatitis and, 524
ventricular arrhythmias caused by, 15
- Halon 112 (dichlorodifluoromethane/Freon 21)
hazard summary for, 561t
toxicity of, 209–210
- Halon 1011 (chlorobromomethane), hazard summary for, 550t
- Halon 1301 (trifluorobromomethane), hazard summary for, 623t
- Halons, toxicity of, **209–210**
- Haloperidol, **451–453**. *See also* antipsychotic drugs, **107–109**
for agitation/delirium/psychosis, 25, 451–453
dystonia caused by, 26t
pharmacokinetics of, 390t

- Haloperidol (*cont.*)
 pharmacology/use of, **451–453**
 seizures caused by, **23t**
 toxicity of, **107t, 452**
 ventricular arrhythmias caused by, **14t, 25, 452**
- Halothane, hepatic failure caused by, **40t**
- Halowax (tetrachloronaphthalene), hazard summary for, **617t**
- Halowax (trichloronaphthalene), hazard summary for, **622t**
- Halowax 1013 (pentachloronaphthalene), hazard summary for, **601t**
- Halowax 1014 (hexachloronaphthalene), hazard summary for, **577t**
- Halowax 1051 (octachloronaphthalene), hazard summary for, **599t**
- “Hammond’s crunch,” **172**
- Hand soap. *See also* low-toxicity products, **286**
 accidental exposure to, **287t**
- Haplopappus heterophyllus*, **313t, 314t. See also** plants, **309–319**
- Harmaline (4,9-dihydro-7-methoxy-1-methyl-3-pyrido(3,4)-indole), **248t, 314t. See also** hallucinogens, **247–249**; plants, **309–319**
- Harmel, **314t. See also** plants, **309–319**
- Hashish (hash/hash oil), **252. See also** marijuana, **252–254**
 toxicity of, **252, 253**
- Hawaiian box jellyfish envenomation, **236–237**
- Hawaiian woodrose, **314t. See also** plants, **309–319**
- Hazardous chemicals
 industrial/occupational exposure to, **510–531**
 carcinogenic potential and, **527, 529**
 emergency medical response to hazardous materials incidents and, **510–518**
 exposure guidelines and, **528–530, 532–628t**
 health hazard information and, **526–528, 532–628t**
 patient evaluation and, **518–526**
 labeling systems for, **511–512, 512–513f, 514f, 529–530**
 toxicity information on, **512–514, 532–628t**
- Hazardous-materials (HazMat) teams, **510**
 for chemical weapons decontamination, **377**
 medical officer on, **510–511**
- Hazardous materials incidents, emergency medical response to, **510–518**
 ambulance transport and, **516**
 assessment of hazard potential and, **511–515, 512–513f, 514f**
 hospital treatment and, **517**
 identification of substances involved in, **511–512, 512–513f, 514f**
 organization of, **510–511, 511f**
 personal protective equipment and, **515**
 recognition of dangerous environment and, **514**
 secondary contamination and, **514–515**
 toxicity information about substances involved in, **512–514**
 victim management and, **515–516**
- Hazard zones, at hazardous materials incident site, **510, 511f**
- HazMat (hazardous-materials) teams, **510**
 medical officer on, **510–511**
- HBO. *See* hyperbaric oxygen therapy, **482–484**
- HBr (hydrogen bromide), hazard summary for, **578t**
- HCHO (formaldehyde), **207–209. See also** caustic and corrosive agents, **157–159**; gases, irritant, **213–215**
 anion gap acidosis caused by, **34t, 158t, 208**
 exposure limits for, **208, 214t, 575t**
 hazard summary for, **575t**
 methanol intoxication and, **208, 260–261**
 toxicity of, **158t, 207–209, 214t**
- HCl (hydrogen chloride). *See also* gases, irritant, **213–215**
 exposure limits for, **214t, 579t**
 hazard summary for, **579t**
 toxicity of, **214t**
- HCN (hydrogen cyanide gas). *See also* cyanide, **177–179**
 as chemical weapon, **373, 375t. See also** warfare agents, chemical, **372–378**
 exposure limits for, **177, 579t**
 hazard summary for, **579t**
 occupational exposure to, **524**
 toxicity of, **177–179, 373, 375t**
- HCTZ. *See* hydrochlorothiazide, **188t**
- HD (sulfur mustard)
 as chemical weapon, **372, 374t. See also** warfare agents, chemical, **372–378**
 toxicity of, **372, 374t**
- Head-down, left sided position, in airway management, **1, 4f**
- Hearing loss, noise-induced, occupational causes of, **522t, 523**
- Heart block, **10–11, 10t**
 cardiac (digitalis) glycosides causing, **10t, 156**
 drugs and toxins causing, **10, 10t**
 hypertension with, drugs and toxins causing, **18t**
 isoproterenol for, **11, 458–459**
 pseudoephedrine/ephedrine/decongestants causing, **10t, 321**
 QRS interval prolongation and, **11, 11t**
- Heart ivy, **313t. See also** plants, **309–319**
- Heart leaf philodendron, **314t. See also** plants, **309–319**
- Heart rate
 assessment of, **9**
 in infants and children, **61t, 62**
- Heath, **314t. See also** plants, **309–319**
- Heat stress, occupational, **524**
- Heatstroke
 hyperthermia caused by, **21t**
 miosis caused by, **30t**
- Heavy metals
 binding agent for, **53t**
 confusion caused by, **24t**
 delirium caused by, **24t**
 neurotoxic effects of, **523**
 pneumonitis caused by, **520**
 poor adsorption to activated charcoal and, **52t**
 renal failure caused by, **39t**
 reproductive disorders associated with, **523**
 seizures caused by, **23t**
- Hedera* spp, **314t. See also** plants, **309–319**
- Hedera glacier*, **313t. See also** plants, **309–319**
- Hedera helix*, **313t, 315t. See also** plants, **309–319**
- Heinz body hemolytic anemia
 dapsone causing, **179, 180**
 methemoglobinemia and, **262**
- Heliotrope (*Heliotropium* spp), **314t. See also** plants, **309–319**
- Hellebore, false, **313t. See also** plants, **309–319**
- Helleborus niger*, **312t. See also** plants, **309–319**
- Helvella* (*Gyromitra*) *esculenta* mushrooms. *See also* mushroom poisoning, **271–275**
 toxicity of, **272t**
 treatment of monomethylhydrazine poisoning caused by, **273**
 pyridoxine for, **273, 499–500**
- Hematologic disorders
 arsenic causing, **117**
 lead causing, **239, 524**
 occupational causes of, **522t, 524**
- Hemlock. *See also* plants, **309–319**
 poison hemlock, **314t**
 rhabdomyolysis caused by, **27t**
 water hemlock (cicutoxin), **314t, 317t**
 odor caused by, **32t**
 seizures caused by, **23t**
- Hemodiafiltration, venovenous
 for metformin overdose, **96**
 for salicylate overdose, **333**
- Hemodialysis
 for barbiturate overdose, **126**
 for bromide poisoning, **141**
 for chlorophenoxy herbicide poisoning, **165**
 for disopyramide overdose, **326**
 for enhanced elimination, **55–57, 56t**
 for ethylene glycol poisoning, **198**
 for formaldehyde poisoning, **209**
 for gabapentin overdose, **87**
 for hyperkalemia, **38**
 for isopropyl alcohol poisoning, **236**
 for lithium overdose, **245**
 for magnesium overdose, **251**
 for metformin overdose, **96**
 for methanol poisoning, **261**

- for *N*-acetylprocainamide (NAPA) overdose, 326
for procainamide overdose, 326
regional anticoagulation in, protamine for reversal of, 497–498
for salicylate overdose, 333
for theophylline overdose, 355
for thiocyanate elimination in nitroprusside overdose, 282, 478
for topiramate overdose, 87
for valproic acid overdose, 364
Hemofiltration, for enhanced elimination, 57
Hemoglobinuria, arsine gas causing, 120
Hemolysis
 arsine gas causing, 119, 524
 dapsone causing, 179, 180
 in methemoglobinemia, 262
 in mushroom poisoning, 272*t*
 renal failure and, 39, 39*t*
Hemolytic anemia
 Heinz body
 dapsone causing, 179, 180
 methemoglobinemia and, 262
 in mushroom poisoning, 272*t*
Hemoperfusion, 56*t*, 57
 for barbiturate overdose, 126
 for carbamazepine overdose, 150
 for chloramphenicol overdose, 84
 for dapsone overdose, 101
 for disopyramide overdose, 326
 for enhanced elimination, 56*t*, 57
 for *N*-acetylprocainamide (NAPA) overdose, 326
 for phenylbutazone overdose, 286
 for procainamide overdose, 326
 for salicylate overdose, 333
 for theophylline overdose, 355
 for valproic acid overdose, 364
Hemorrhagic fevers, viral, as biological weapons, 369*t*. *See also* warfare agents, biological, 367–372
Henbane/black henbane, 311*t*, 314*t*. *See also* plants, 309–319
Heparin
 for ergot overdose, 190
 protamine for overdose of, 497–498
 teratogenic effects of, 59*t*
Hepatic failure/hepatotoxicity, 40, 40*t*
 acetaminophen causing, 40*t*, 66, 67, 67*f*
 in amatoxin-type mushroom poisoning, 40*t*, 272*t*, 274
 dantrolene causing, 431
 drugs and toxins causing, 40*t*
 ethanol causing, 40*t*, 191
 hypoglycemia in, 35*t*
 occupational exposures and, 522*t*, 524
Hepatic steatosis, antiretroviral drugs causing, 111
Hepatitis
 chemical, 524
 in mushroom poisoning, 272*t*
Heptachlor. *See also* chlorinated hydrocarbons, 161–162
 hazard summary for, 577*t*
 toxicity of, 161*t*
n-Heptane, hazard summary for, 577*t*
2-Heptanone (methyl-*n*-amyl ketone), hazard summary for, 588*t*
2,6-dimethyl-4-Heptanone (diisobutyl ketone), hazard summary for, 564*t*
3-Heptanone (ethyl butyl ketone), hazard summary for, 570*t*
5-methyl-3-Heptanone (ethyl amyl ketone), hazard summary for, 570*t*
Heptenophos. *See also* organophosphates and carbamates, 291–295
 toxicity of, 292*t*
Herbal/alternative products, toxicity of, 215–218, 216–217*t*
 “Herbal Ecstasy,” 320. *See also* ephedrine, 320–322
Herbicides
 chlorophenoxy, 164–165
 rhabdomyolysis caused by, 27*t*, 164
 toxicity of, 164–165
 paraquat and diquat, 296–298
Heroin (diacetylmorphine), 286, 289*t*. *See also* opiates/opioids, 286–291
 with cocaine (speedball), 171. *See also* cocaine, 171–173
 pharmacokinetics of, 390*t*
 toxicity of, 286, 289*t*
 withdrawal from, in neonates, 62–63
Herring (pickled), monoamine oxidase inhibitor interaction and, 270*t*
Heterodon envenomation, 343*t*. *See also* snakebites, 343–346
Heteromeles arbutifolia, 317*t*. *See also* plants, 309–319
Hexachlorobenzene. *See also* chlorinated hydrocarbons, 161–162
 toxicity of, 161*t*
Hexachlorobutadiene, hazard summary for, 577*t*
Hexachlorocyclopentadiene, hazard summary for, 577*t*
Hexachloroethane (perchloroethane), hazard summary for, 577*t*
Hexachloronaphthalene, hazard summary for, 577*t*
Hexachlorophene. *See also* phenols, 302–303
 toxicity of, 302
Hexacyanoferrate, ferric (Prussian blue), 499
 as binding agent, 53*t*, 330*t*
 pharmacology/use of, 499
 for radiation poisoning, 330*t*, 499
 for thallium poisoning, 353, 499
Hexalen. *See* altretamine, 104*t*
Hexamethylphosphoramide, hazard summary for, 577*t*
Hexane isomers, hazard summary for, 578*t*
n-Hexane
 hazard summary for, 578*t*
 job processes associated with exposure to, 521*t*
 neuropathy caused by, 31*t*
2-Hexanone (methyl *n*-butyl ketone)
 hazard summary for, 589*t*
 neuropathy caused by, 31*t*
5-methyl-2-Hexanone (methyl isoamyl ketone), hazard summary for, 592*t*
Hexavalent chromium compounds, toxicity of, 167–169
Hexacyclium. *See also* anticholinergic agents, 84–86
 toxicity of, 85*t*
Hexone (methyl isobutyl ketone), hazard summary for, 592*t*
sec-Hexyl acetate, hazard summary for, 578*t*
Hexylcaine. *See also* anesthetics, local, 74–77
 toxicity of, 75*t*
Hexylene glycol, hazard summary for, 578*t*
Hexyresorcinol. *See also* antiseptics/disinfectants, 109–111
 toxicity of, 109, 110
HF (hydrogen fluoride/hydrofluoric acid), 221–224
 calcium for contamination/poisoning caused by, 47*t*, 223, 424–426
 exposure limits for, 214*t*, 222, 579*t*
 hazard summary for, 579*t*
 occupational exposure to, 521*t*, 523
 topical treatment for exposure to, 47*t*, 223
 toxicity of, 158*t*, 200*t*, 214*t*, 221–224
HI-6, 493. *See also* oximes, 492–494
 for nerve agent exposures, 377
HIE (hyperinsulinemia-euglycemia) therapy, 146, 450–451, 455–456
Highly active antiretroviral therapy (HAART), 111. *See also* antiviral and antiretroviral agents, 111–115
High-pressure injection injuries, work-related, 522
Hippastrum equestre, 311*t*. *See also* plants, 309–319
Hippobroma longiflora, 317*t*. *See also* plants, 309–319
Hismanal. *See* astemizole, 97*t*, 98
History
 in diagnosis of poisoning, 28–29
 occupational exposure, 518–520, 521*t*
Hivid. *See* zalcitabine, 113*t*
HIV infection/AIDS, treatment of, 111–115, 112–113*t*
HLO-7, 493. *See also* oximes, 492–494
 for nerve agent exposures, 377
“Hog” (slang). *See* phencyclidine, 300–302
Hognose snake envenomation, 343*t*. *See also* snakebites, 343–346
Holiday Household Insect Fogger. *See* pyrethrins/pyrethroids (fenvalerate), 322–324, 323*t*
1,1,1-trichloroethane, 359–361
Holly berries, 314*t*. *See also* plants, 309–319
Honeybee (Apidae) envenomation, 225–226
Honeysuckle, 314*t*. *See also* plants, 309–319

- Hops. *See also* plants, **309–319**
European, 314t
wild, 314t
- Horizontal gaze nystagmus, in diagnosis of poisoning, 30
- Hormones, as antineoplastic agents. *See also* antineoplastic agents, **100–107**
toxicity of, 100, 103t
- Hornet envenomation, 225–226
- Horse chestnut, 314t. *See also* plants, **309–319**
- Hospital sterilizer
reproductive disorders associated with use of, 523
toxic exposure associated with use of, 521t
- Hospital treatment, for victims of hazardous materials incident, 516–517
decontamination and, 517
- Hot tub disinfection, toxic exposures and, 521t
- Hot water, for stonefish (*scorpaenidae*) envenomation, 244
- Hot zone (Exclusion Zone), at hazardous materials incident site, 510, 511f
victim decontamination in, 515–516
victim stabilization in, 515
- Household products, nontoxic or minimally toxic, accidental exposure to, **286**, 287t, 288t
- HPA (2-hydroxypropyl acrylate), hazard summary for, 580t
- Human immunodeficiency virus (HIV), treatment for infection with, **111–115**, 112–113t
- Human regular insulin. *See also* insulin, 93–96, **455–456**
pharmacokinetics of, 391t
toxicity of, 94t
- Human tetanus immune globulin, 352, **503–505**
pharmacology/use of, **503–505**
- Human tissue-derived botulism immune globulin (BIG), for infant botulism, 138, 420
- Humulin R. *See* insulin, 93–96, **455–456**
- Humulus lupulus*, 314t. *See also* plants, **309–319**
- Hura crepitans*, 317t. *See also* plants, **309–319**
- Hurricane. *See* benzocaine, 75, 75t, 76
- Hyacinth (*Hyacinthus*), 314t. *See also* plants, **309–319**
- Hyaluronidase, for antineoplastic infusion extravasation, 106
- Hycamtin. *See* topotecan, 104t
- Hycodan (hydrocodone and homatropine). *See* hydrocodone, 289t
- Hycimine. *See*
acetaminophen, **66–69**
caffeine, **142–144**
chlorpheniramine, 97t
hydrocodone, 289t
phenylephrine, **320–322**
- Hydergine. *See* ergoloid derivatives, 189–190
- Hydralazine
hypotension caused by, 16t
pharmacokinetics of, 390t
toxicity of, 365–366
- Hydrangea/*Hydrangea* spp., 314t. *See also* plants, **309–319**
- Hydrastis* spp., 217t, 313t. *See also* herbal and alternative products, **215–218**; plants, **309–319**
- Hydrated lime (calcium hydroxide), hazard summary for, 545t
- Hydrazine
hazard summary for, 578t
hepatotoxicity of, 524
job processes associated with exposure to, 521t
- Hydrazoic acid
pharmacokinetics of, 390t
sodium salt of. *See also* azide, sodium, **122–124**
hazard summary for, 612t
toxicity of, 122–123
toxicity of, 122–123
- Hydrea. *See* hydroxyurea, 105t
- Hydrocarbons, **219–221**, 219t
aliphatic, toxicity of, 219
aromatic
particulate polycyclic, hazard summary for, 552t
toxicity of, 219, 219t
ventricular arrhythmias caused by, 14t, 15, 526–527
aspiration of, 219, 220, 221, 527
bronchospasm caused by, 9t
hypoxia caused by, 7t, 8
chlorinated, **161–162**
binding agent for, 53t
cardiovascular disease caused by, 161, 523
central nervous system effects and, 161, 523
esmolol for poisoning caused by, 443–444
hepatic failure caused by, 40t, 161
job processes associated with exposure to, 521t
pharmacokinetics of, 161
propranolol for poisoning caused by, 496–497
renal failure caused by, 39t, 161
seizures caused by, 23t, 161
toxicity of, **161–162**
ventricular arrhythmias caused by, 14t, 162, 526–527
fluorinated (freons), **209–210**
exposure limits for, 209
propranolol for poisoning caused by, 210, 496–497
toxicity of, **209–210**
ventricular arrhythmias caused by, 14t, 209, 210, 526–527
- halogenated
toxicity of, 219, 219t
hepatitis and, 524
ventricular arrhythmias caused by, 15
toxicity of, **219–221**, 219t, 526–527
arrhythmias and, 14t, 15, 162, 526–527
cardiovascular disorders and, 161, 523
central nervous system effects and, 161, 523
in children, 60t
skin/dermatologic effects and, 526
- Hydrochlorothiazide. *See also* diuretics, **187–189**
for lithium-induced nephrogenic diabetes insipidus, 36, 245
pharmacokinetics of, 390t
toxicity of, 188t
- Hydrocodone, 289t. *See also* opiates/opioids, **286–291**
pharmacokinetics of, 390t
toxicity of, 289t
in toxicology screens, 41t
- Hydrocortisone
for anaphylactic/anaphylactoid reactions, 28t
for hyponatremia in adrenal insufficiency, 37
for phosphine/phosphide poisoning, 307
- Hydrocortisone cream. *See also* low-toxicity products, **286**
accidental exposure to, 287t
- Hydrocotyle asiatica*, 313t. *See also* plants, **309–319**
- Hydrocyanic acid. *See also* hydrogen cyanide gas, **177–179**
hazard summary for, 579t
- HydroDIURIL. *See* hydrochlorothiazide, 188t
- Hydroflumethiazide. *See also* diuretics, **187–189**
pharmacokinetics of, 390t
toxicity of, 188t
- Hydrofluoric acid, **221–224**
calcium for contamination/poisoning caused by, 47t, 223, 424–426
exposure limits for, 222, 579t
hazard summary for, 579t
occupational exposure to, 521t, 523
topical treatment for exposure to, 47t, 223
toxicity of, 158t, **221–224**
- Hydrogen bromide, hazard summary for, 578t
- Hydrogen chloride. *See also* gases, irritant, **213–215**
exposure limits for, 214t, 579t
hazard summary for, 579t
toxicity of, 214t
- Hydrogen cyanide gas. *See also* cyanide, **177–179**
as chemical weapon, 373, 375t. *See also* warfare agents, chemical, **372–378**
exposure limits for, 177, 579t
hazard summary for, 579t
occupational exposure to, 524
toxicity of, 177–179, 373, 375t
- Hydrogen fluoride, **221–224**
calcium for contamination/poisoning caused by, 47t, 223, 424–426
exposure limits for, 214t, 222, 579t
hazard summary for, 579t
occupational exposure to, 521t
topical treatment for exposure to, 47t, 223
toxicity of, 158t, 200t, 214t, **221–224**
- Hydrogen peroxide. *See also* antiseptics/disinfectants, **109–111**
hazard summary for, 579t
toxicity of, 109, 110

- Hydrogen peroxide 3%. *See also* low-toxicity products, **286**
accidental exposure to/toxicity of, 110, 287*t*
- Hydrogen phosphide (phosphine), **306–307**
exposure limits for, 306, 603*t*
hazard summary for, 603*t*
job processes associated with exposure to, 521*t*
toxicity of, **306–307**
- Hydrogen selenide (selenium hydride). *See also* selenium, **337–339**
hazard summary for, 579*t*
toxicity of, 338, 338*t*
- Hydrogen selenite (selenious acid). *See also* selenium, **337–339**
toxicity of, 337–338, 338*t*
in children, 60*t*
- Hydrogen sulfide, **224–225**
anion gap/lactic acidosis caused by, 34*t*
coma caused by, 19*t*, 224
exposure limits for, 224, 580*t*
hazard summary for, 580*t*
hypoxia caused by, 7*t*, 8
nitrites for poisoning caused by, 224, 476–477
occupational exposure to, 521*t*, 523, 524
odor caused by, 32*t*
seizures caused by, 23*t*, 224
stupor caused by, 19*t*, 224
tachycardia caused by, 13*t*
toxicity of, **224–225**
central nervous system effects and, 523
- Hydrolysis, for chemical weapons decontamination, 378
- Hydromorphone, 289*t*. *See also* opiates/opioids, **286–291**
pharmacokinetics of, 390*t*
toxicity of, 289*t*
- Hydrophidæ envenomation, 343*t*. *See also* snakebites, **343–346**
- Hydroquinone. *See also* phenols, **302–303**, plants, **309–319**
hazard summary for, 580*t*
toxicity of, 302, 310*t*
- Hydroxocobalamin (vitamin B₁₂), **453–454**
for cyanide poisoning, 178, 453–454
nitroprusside-induced, 282, 453–454, 478
in smoke inhalation, 342
pharmacology/use of, **453–454**
- Hydroxybenzene. *See also* phenols, **302–303**
hazard summary for, 601*t*
- 4-Hydroxybutanoic acid. *See* gamma-hydroxybutyrate (GHB), 210–213, 211*t*
- 4-Hydroxybutyrate, sodium. *See* gamma-hydroxybutyrate (GHB), 210–213, 211*t*
- β-Hydroxybutyrate levels, in differentiation of ethylene glycol poisoning from alcoholic ketoacidosis, 192, 197–198
- Hydroxychloroquine
diazepam for overdose of, 415–418
pharmacokinetics of, 390*t*
toxicity of, 165–167
- 5-Hydroxy-*N,N*-dimethyltryptamine (bufotenine). *See also* hallucinogens, **247–249**; herbal and alternative products, **215–218**
toxicity of, 216*t*, 248*t*
- Hydroxymethylbenzene (cresol). *See also* phenols, **302–303**
hazard summary for, 554*t*
toxicity of, 302
- 4-Hydroxy-4-methyl-2-pentanone (diacetone alcohol), hazard summary for, 557*t*
- 2-Hydroxypropyl acrylate, hazard summary for, 580*t*
- Hydroxyurea. *See also* antineoplastic agents, **100–107**
toxicity of, 105*t*
- Hydroxyzine. *See also* antihistamines, **96–98**
pharmacokinetics of, 390*t*
seizures caused by, 23*t*
toxicity of, 97*t*
- Hyland's Teething Tablets. *See*, atropine, 85*t*, **412–413**
- Hymenoptera envenomation, **225–226**
anaphylactic reaction caused by, 28*t*, 226
- Hyoscyamine, pharmacokinetics of, 390*t*
- L-Hyoscyamine. *See also* anticholinergic agents, **84–86**
pharmacokinetics of, 392*t*
toxicity of, 85*t*
- Hyoscyamus* spp., 311*t*, 314*t*, 315*t*. *See also* plants, **309–319**
- Hyoscyamus niger*, 311*t*. *See also* plants, **309–319**
- Hyperammonemia, L-carnitine for, 426–427
- Hyperbaric oxygen therapy, **482–484**
for carbon monoxide poisoning, 153, 153*t*, 482–484
in smoke inhalation, 342
for cyanide poisoning, 178
for hydrogen peroxide ingestion, 111
for *Loxosceles* spider envenomation, 348
for methemoglobinemia, 263
- Hypercarbia, in ventilatory failure, 7
- Hyperglycemia, 34–35, 35*t*
causes of, 35*t*
diazoxide causing, 35*t*, 434
epinephrine causing, 35*t*, 442
- Hypericum perforatum* (St. John's Wort), 217*t*, 269–271, 317*t*. *See also* herbal and alternative products, **215–218**; monoamine oxidase inhibitors, **269–271**; plants, **309–319**
- Hyperinsulinemia-euglycemia (HIE) therapy, 146, 450–451, 455–456
- Hyperkalemia, 37–38, 38*t*
angiotensin blockers/ACE inhibitors causing, 38*t*, 77
beta-adrenergic blockers causing, 38*t*, 132
calcium for, 38, 424–426
cardiac (digitalis) glycosides causing, 38*t*, 156
causes of, 38*t*
glucose/dextrose with insulin for, 38, 450–451, 455–456
in hydrogen fluoride and hydrofluoric acid poisoning/contamination, 222, 223
QRS interval prolongation in, 11, 11*t*, 12*t*, 38
in renal failure, 38*t*, 39
- Hypermagnesemia, 250–251. *See also* magnesium, **250–251**, **463–464**
calcium for, 424–426
cathartics for gastrointestinal decontamination and, 52
- Hypernatremia, 35–36, 36*t*
cathartics for gastrointestinal decontamination and, 52
drugs and toxins causing, 36*t*
- Hyperosmolality, cathartics for gastrointestinal decontamination and, 52
- "Hyperoxygen therapy," with hydrogen peroxide, 110
- Hypersensitivity pneumonitis (allergic alveolitis)
molds causing, 268
occupational causes of, 522
- Hypersensitivity reactions, bronchospasm caused by, 9, 9*t*
- Hyperstat. *See* diazoxide, **433–434**
- Hypertension, **17–18**, 18*t*
amphetamines causing, 17, 18*t*, 74
in children, 62
drugs and toxins causing, 17, 18*t*
epinephrine causing, 18*t*, 442
with neurologic abnormality, 10
pseudoephedrine/ephedrine/decongestants causing, 18*t*, 321, 322
treatment of, 18
diuretics for, **187–189**
esmolol for, 18, 443–444
labetalol for, 18, 459–460
nitroprusside for, 18, 282, 477–479
phenolamine for, 18, 322, 487–488
propranolol for, 18, 496–497
- Hypertensive crisis, diazoxide for, 433–434
- Hyperthermia, **21–22**, 21*t*
in agitation/delirium/psychosis, 25
in amantadine overdose, 70
amphetamines causing, 21*t*, 73
cocaine causing, 21*t*, 172
drugs and toxins causing, 21*t*
hypotension and, 16, 16*t*
malignant, 21*t*, 22
rigidity caused by, 22, 26, 26*t*
treatment of, 22
dantrolene in, 22, 431–432
renal failure caused by, 39*t*
rhabdomyolysis associated with, 27*t*, 39*t*
treatment of, 22
dantrolene for, 431–432
neuromuscular blocking agents for, 22, 472–475

- Hypertonic saline, for hyponatremia, 37
 Hypertonic sodium bicarbonate. *See* sodium bicarbonate, 419–420
 Hyperventilation, for tricyclic antidepressant overdose, 92
 Hypnotics. *See* barbiturates, 124–126; sedative-hypnotics, 335–337
 Hypocalcemia
 calcium for, 424–426
 in hydrogen fluoride and hydrofluoric acid poisoning/contamination, 222, 223
 Hypochlorite
 ammonia mixtures and, chloramine gas released by, 70
 calcium/sodium, for chemical weapons decontamination, 378
 in household bleach, accidental ingestion of, 163
 toxicity of, 162–164
 Hypoglycemia, 35, 35*t*
 antidiabetic agents causing, 35, 93–96
 beta-adrenergic blockers causing, 132
 causes of, 35*t*
 ethanol causing, 35*t*, 191
 glucose for, 95, 450–451
 octreotide for, 480–481
 Hypoglycemic agents. *See* antidiabetic (hypoglycemic) agents, 93–96
 Hypokalemia, 38–39, 38*t*
 in barium poisoning, 38, 38*t*, 126, 127
 causes of, 38*t*
 diuretics causing, 38*t*, 39, 188
 epinephrine causing, 38*t*, 442
 potassium for, 491–492
 theophylline causing, 38, 38*t*
 Hypomagnesemia, magnesium for, 251, 463–464
 Hyponatremia, 36–37, 36*t*
 drugs and toxins causing, 36*t*
 Hypopituitarism, hypoglycemia in, 35*t*
 Hypotension, 16–17, 16*t*
 angiotensin blockers/ACE inhibitors causing, 77
 barbiturates causing, 16*t*
 beta-adrenergic blockers causing, 16*t*, 132
 calcium antagonists causing, 16*t*, 144–145, 145 in children, 62
 drugs and toxins causing, 16, 16*t*
 hyperthermia and, 16, 16*t*
 hypothermia and, 16, 16*t*, 17, 21
 nitrates/nitrites causing, 279
 treatment of, 16–17
 dopamine for, 16, 17, 438–439
 epinephrine for, 442–443
 fluid/saline therapy, 10, 16, 17
 norepinephrine for, 17, 479–480
 Hypothermia, 20–21, 20*t*
 barbiturates causing, 20*t*, 125
 bradycardia and, 11, 21
 drugs and toxins causing, 20, 20*t*
 electrocardiographic changes in, 11, 13*t*, 20
 hypotension and, 16, 16*t*, 17, 21
 treatment of, 21. *See also* rewarming, 11, 17, 21
 Hypovolemia
 hypernatremia with, treatment of, 36
 hyponatremia with, 36
 treatment of, 37
 Hypoxia, 7–8, 7*t*
 anion gap/lactic acidosis associated with, 34*t*
 causes of, 7–8, 7*t*
 cellular, 7*t*, 8
 coma and, 19*t*
 seizures and, 23*t*
 stupor and, 19*t*
 tachycardia and, 13*t*
 oxygen therapy for, 8, 482–484
 treatment of, 8
 in ventilatory failure, 7
 Hytrin. *See* terazosin, 365–366
 IARC (International Agency for Research on Cancer), evaluation of potential carcinogens by, 527
 Ibotenic acid, poisoning with mushrooms containing, 272*t*, 273. *See also* mushroom poisoning, 271–275
 IBP (kitacin). *See also* organophosphates and carbamates, 291–295
 toxicity of, 292*t*
 Ibriumomab tiuxetan. *See also* antineoplastic agents, 100–107
 toxicity of, 104*t*
 Ibuprofen. *See also* nonsteroidal anti-inflammatory drugs, 283–286
 anion gap acidosis caused by, 34*t*, 285
 pharmacokinetics of, 285, 390*t*
 renal failure caused by, 39*t*, 285
 toxicity of, 284*t*, 285
 Ibutilide, ventricular arrhythmias caused by, 14*t*
 “Ice”. *See* methamphetamine, 72, 73*t*
 Ichthammol (ichthylol). *See also* antiseptics/disinfectants, 109–111
 toxicity of, 109, 110
 Idamycin. *See* idarubicin, 102*t*, 106
 Idarubicin. *See also* antineoplastic agents, 100–107
 extravasation of, 106
 toxicity of, 102*t*, 106
 IDLH (immediately dangerous to life or health) designation, 529
 Ifex. *See* ifosfamide, 101*t*
 Ifosfamide. *See also* antineoplastic agents, 100–107
 toxicity of, 101*t*
 IgE (immunoglobulin E), in anaphylactic/anaphylactoid reactions, 27, 28*t*
 Ileus, in diagnosis of poisoning, 30–31
Ilex aquifolium, 314*t*. *See also* plants, 309–319
Ilex glabra, 314*t*. *See also* plants, 309–319
Ilex paraguayensis, 315*t*. *See also* plants, 309–319
 Imatinib. *See also* antineoplastic agents, 100–107
 toxicity of, 105*t*
 Imdur. *See* isosorbide mononitrate, 279–280
 Imipramine. *See also* tricyclic antidepressants, 90–93
 pharmacokinetics of, 390*t*
 toxicity of, 88*t*
 in children, 60*t*
 in toxicology screens, 41*t*
 Immediately dangerous to life or health (IDLH) designation, 529
 Immobility
 renal failure caused by, 39*t*
 rhabdomyolysis caused by, 27*t*, 39*t*
 Immune globulin
 botulism, human tissue-derived (BIG), for infant botulism, 138, 420
 tetanus, 352, 503–505
 pharmacology/use of, 503–505
 Immunoglobulin E (IgE), in anaphylactic/anaphylactoid reactions, 27, 28*t*
 Immunotherapy allergen extracts, anaphylactic reaction caused by, 28*t*
 Imodium. *See* loperamide, 246–247
 Inamrinone, 454–455
 for calcium antagonist overdose, 146, 454–455
 pharmacology/use of, 454–455
 Inapsine. *See* droperidol, 107*t*, 451–453
 Incapacitating agents, as chemical weapons, 373, 376, 377. *See also* warfare agents, chemical, 372–378
 Incense. *See also* nontoxic products, 286
 accidental exposure to, 287*t*
 Incident Commander, at hazardous materials incident site, 510
 Incident Command System, for response to hazardous materials incidents, 510–511, 511*f*
 Indapamide. *See also* diuretics, 187–189
 pharmacokinetics of, 390*t*
 toxicity of, 188*t*
 ventricular arrhythmias caused by, 14*t*
 Indelible markers. *See also* nontoxic products, 286
 accidental exposure to, 287*t*
 Indene, hazard summary for, 580*t*
 Inderal. *See* propranolol, 132*t*, 496–497
 Indiride. *See*
 hydrochlorothiazide, 188*t*
 propranolol, 132*t*, 496–497
 Indian currant, 314*t*. *See also* plants, 309–319
 Indian tobacco, 314*t*. *See also* plants, 309–319

- Indinavir. *See also* antiviral and antiretroviral agents, **111–115**
pharmacokinetics of, 390*t*
toxicity of, 113*t*, 114
- Indium, hazard summary for, 580*t*
- Indocin. *See* indomethacin, 284*t*
- Indomethacin. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
for lithium-induced nephrogenic diabetes insipidus, 36, 245
pharmacokinetics of, 390*t*
toxicity of, 284*t*
- Indoramin
pharmacokinetics of, 390*t*
toxicity of, 365–366
- Induction anesthesia, propofol for, 494–496
- Inert gases, hypoxia caused by, 7*t*
- Infant botulism, 136–138
treatment of, 138, 420
- INH (isoniazid), **233–234**
anion gap/lactic acidosis caused by, 34*t*, 233
neuropathy caused by, 31*t*
pharmacokinetics of, 233, 391*t*
pyridoxine for overdose of, 234, 499–500
seizures caused by, 23*t*, 233
toxicity of, 82*t*, **233–234**
- Inhalation decontamination, 47
- Inhaled irritants. *See also* gases, irritant, **213–215**
accidental exposure to, 288*t*
occupational exposure to, 520
- Inhalers, nicotine. *See also* nicotine, **277–278**
toxicity of, 277
- Ink (without aniline dyes). *See also* nontoxic products, **286**
accidental exposure to, 287*t*
- Inkberry, 314*t*. *See also* plants, **309–319**
- Ink jet cleaner (slang). *See* 1,4-butanediol, 210–213, 211*t*
- Inner G. *See* 1,4-butanediol, 210–213, 211*t*
- Incor. *See* inamrinone, **454–455**
- Inocybe* mushrooms. *See also* mushroom poisoning, **271–275**
toxicity of, 272*t*
- Inorganic salts, poor adsorption to activated charcoal and, 52*t*
- Inotropin. *See* dopamine, **438–439**
- INR (International Normalized Ratio), in anticoagulant-based rodenticide poisoning, 379
- Insect envenomation, **225–226**
anaphylactic reaction caused by, 28*t*, 226
- Insecticide poisoning, pralidoxime (2-PAM)/oximes for, 294–295, 492–494
- Insecticides. *See*
chlorinated hydrocarbons, **161–162**
organophosphates and carbamates, **291–295**
pyrethrins/pyrethroids, **322–324**
- Insom-X. *See* gamma-butyrolactone, 210–213, 211*t*
- Insulin, **455–456**. *See also* antidiabetic (hypoglycemic) agents, **93–96**
with glucose/dextrose, for calcium antagonist overdose/hyperkalemia, 38, 146, 450–451, 455–456
for hyperglycemia, 35
hypoglycemia caused by, 35*t*, 95, 96, 455
pharmacokinetics of, 94*t*, 390–391*t*
pharmacology/use of, **455–456**
toxicity of, 93–96, 94*t*, 455
- Insulin aspart. *See also* insulin, 93–96, **455–456**
pharmacokinetics of, 390*t*
toxicity of, 94*t*
- Insulin-dependent diabetes mellitus, Vacor (PNU) causing, 361
- Insulin glargine. *See also* insulin, 93–96, **455–456**
pharmacokinetics of, 390*t*
toxicity of, 94*t*
- Insulin zinc (lente). *See also* insulin, 93–96, **455–456**
pharmacokinetics of, 391*t*
toxicity of, 94*t*
- Intensive care, admission to, 58
- Interferon alpha 2a. *See also* antineoplastic agents, **100–107**
toxicity of, 105*t*
- Interferon alpha 2b. *See also* antineoplastic agents, **100–107**
toxicity of, 105*t*
- Interleukin-2 (aldesleukin). *See also* antineoplastic agents, **100–107**
toxicity of, 104*t*
- Intermediate syndrome, inadequate 2-PAM dosing and, 493
- Intermittent mandatory ventilation, 7
- International Agency for Research on Cancer (IARC), evaluation of potential carcinogens by, 527
- International Normalized Ratio (INR), in anticoagulant-based rodenticide poisoning, 379
- Interstitial nephritis, occupational causes of, 524
- Intracranial hemorrhage, pseudoephedrine/ephedrine/decongestants causing, 321
- Intracranial hypertension
pentobarbital in management of, 485–486
in vitamin A toxicity, mannitol for, 464–465
- Intravenous fluid therapy
for arsine gas exposure, 120
for bromide poisoning, 141
for hypernatremia, 36
for hyponatremia, 37
hyponatremia caused by, 36*t*
for hypotension, 10, 16, 17
in management of circulatory problems, 10
for rhabdomyolysis, 27
- Intron A. *See* interferon alpha 2b, 105*t*
- Intubation, endotracheal, **4–6, 5*f***
nasotracheal route for, 5, 5*f*
orotracheal route for, 5–6, 5*f*
neuromuscular blockers for, 5–6, 472–475
for ventilatory failure, 7
- Inversine. *See* mecamlamine, 278
- Invigorate. *See* gamma-butyrolactone, 210–213, 211*t*
- Invirase. *See* saquinavir, 113*t*
- Iodide. *See also* iodine, **226–228**
potassium (KI), **456–457**
pharmacology/use of, **456–457**
for radiation poisoning, 330*t*, 456–457
toxicity of, 226
sodium, toxicity of, 226
- Iodinated contrast media, anaphylactoid reaction caused by, 28*t*
- Iodine, **226–228**
exposure limits for, 227, 581*t*
hazard summary for, 581*t*
toxicity of, **226–228**
- Iodine-131. *See also* radiation (ionizing), **327–331**
chelating/blocking agents for exposure to, 330*t*
potassium iodide, 330*t*, 456–457
- Iodochlorhydroxyquin. *See also* iodine, **226–228**
toxicity of, 226
- Iodofenphos (jodfenphos). *See also* organophosphates and carbamates, **291–295**
toxicity of, 292*t*
- Iodoform. *See also* iodine, **226–228**
toxicity of, 226
- Iodomethane (methyl iodide), hazard summary for, 592*t*
- Iodophors. *See also* iodine, **226–228**
toxicity of, 226
- Ionamin. *See* phentermine, 72, 73*t*
- Ionizing radiation
occupational exposure to, 524
toxicity of, **327–331**
- Iopanoic acid, for thyroid hormone overdose, 357
- Ipecac syrup, **228–229, 457–458**
for emesis in gastrointestinal decontamination, 48–49, 457–458
in pediatric patient, 49, 458
in pregnant patient, 59, 458
pharmacology/use of, **457–458**
toxicity of, **228–229, 457–458**
- Ipomoea violacea*, 315*t*, 318*t*. *See also* plants, **309–319**
- Ipratropium. *See also* anticholinergic agents, **84–86**
for bronchospasm, 9
pharmacokinetics of, 391*t*
toxicity of, 85*t*
- Irbesartan, pharmacokinetics of, 391*t*
- Irinotecan. *See also* antineoplastic agents, **100–107**
toxicity of, 104*t*
- Iris/Iris spp, 313*t*, 314*t*. *See also* plants, **309–319**

- Isolan. See also organophosphates and carbamates, 291–295**
 toxicity of, 293*t*
- Isoniazid (INH), 233–234**
 anion gap/lactic acidosis caused by, 34*t*, 233
 neuropathy caused by, 31*t*
 pharmacokinetics of, 233, 391*t*
 pyridoxine for overdose of, 234, 499–500
 seizures caused by, 23*t*, 233
 toxicity of, 82*t*, **233–234**
- Isophane insulin. See also insulin, 93–96, 455–456**
 pharmacokinetics of, 390*t*
 toxicity of, 94*t*
- Isophorone, hazard summary for, 582*t***
- Isophorone diisocyanate, hazard summary for, 582*t***
- Isoprocab (MIPC). See also organophosphates and carbamates, 291–295**
 toxicity of, 293*t*
- Isopropanamide. See also anticholinergic agents, 84–86**
 toxicity of, 85*t*
- Isopropanol (isopropyl alcohol), 234–236**
 for chemical exposures to skin, 47*t*
 elimination of, 56*t*
 estimation of level of from osmolar gap, 33*t*, 235
 exposure limits for, 235, 582*t*
 hazard summary for, 582*t*
 odor caused by, 32*t*, 235
 osmolar gap elevation caused by, 32*t*, 235
 pharmacokinetics of, 235, 391*t*
 toxicity of, **234–236**
 in toxicology screens, 41*t*
 interferences and, 44*t*
 volume of distribution of, 56*t*, 235, 391*t*
- 2-Isopropoxyethanol, hazard summary for, 582*t***
- o*-Isopropoxyphenyl *N*-methylcarbamate (propoxur). See also organophosphates and carbamates, 291–295**
 hazard summary for, 607*t*
 toxicity of, 293*t*
- Isopropyl acetate, hazard summary for, 582*t***
- Isopropyl alcohol, 234–236**
 for chemical exposures to skin, 47*t*
 elimination of, 56*t*
 estimation of level of from osmolar gap, 33*t*, 235
 exposure limits for, 235, 582*t*
 hazard summary for, 582*t*
 odor caused by, 32*t*, 235
 osmolar gap elevation caused by, 32*t*, 235
 pharmacokinetics of, 235
 toxicity of, **234–236**
 in toxicology screens, 41*t*
 interferences and, 44*t*
 volume of distribution of, 56*t*, 235
- Isopropylamine, hazard summary for, 583*t***
- Isopropylbenzene (cumene), hazard summary for, 555*t***
- Isopropyl cellosolve (2-isopropoxyethanol), hazard summary for, 582*t***
- Isopropyl ether, hazard summary for, 583*t***
- Isopropyl glycidyl ether, hazard summary for, 583*t***
- Isoproterenol, 458–459**
 for atrioventricular (AV) block, 11, 458–459
 for atypical/polymorphic ventricular tachycardia (torsade de pointes), 15, 458–459
 for beta-adrenergic blocker overdose, 133, 458–459
 for bradycardia, 11, 458–459
 pharmacology/use of, **458–459**
- Isosoptin. See verapamil, 144, 145, 145*t*, 146**
- Isordil. See isosorbide dinitrate, 279–280**
- Isosorbide dinitrate**
 pharmacokinetics of, 391*t*
 toxicity of, 279–280
- Isosorbide mononitrate**
 pharmacokinetics of, 391*t*
 toxicity of, 279–280
- Isosathion. See also organophosphates and carbamates, 291–295**
 toxicity of, 292*t*
- Isradipine. See also calcium antagonists, 144–147**
 pharmacokinetics of, 391*t*
 toxicity of, 144, 145*t*
 ventricular arrhythmias caused by, 14*t*
- Isuprel. See isoproterenol, 458–459**
- Itai-itai disease, cadmium causing, 142**
- Ivy, 314*t*. See also plants, 309–319**
 American, 311*t*
 Boston, 311*t*
 devils, 313*t*
 English, 313*t*
 glacier, 313*t*
 heart, 313*t*
 oakleaf, 315*t*
 poison, 316*t*
- Ivy bush, 314*t*. See also plants, 309–319**
- J wave, in hypothermia, 11, 13*t*, 20**
- Jack-in-the-pulpit, 314*t*. See also plants, 309–319**
- Jaggery palm, 314*t*. See also plants, 309–319**
- Jalap root, 314*t*. See also plants, 309–319**
- Japanese beech, 311*t*. See also plants, 309–319**
- Jasco Chemical Premium Paint and Epoxy Remover. See methanol, 260–261**
 methylene chloride, **265–267**
- Jasco Chemical Speedomatic Paint Remover. See methanol, 260–261**
 methylene chloride, **265–267**
- Jasmine, Carolina, 314*t*. See also plants, 309–319**
- Jasminum officinale*, 314*t*. See also plants, 309–319**

- Jasmolin I or II (pyrethrum), hazard summary for, 609t
Jatropha spp, 311t, 316t. *See also* plants, **309–319**
 “Jaw thrust” maneuver, 1, 4f
 Jellyfish envenomation, **236–237**
 Jequirity bean, 314t. *See also* plants, **309–319**
 Jerusalem cherry, 314t. *See also* plants, **309–319**
 Jessamine. *See also* plants, **309–319**
 Carolina or yellow (*Gelsemium sempervirens*), 314t
 day or night (*Cestrum* spp), 314t
 poet’s, 314t
 “Jet” (slang). *See* ketamine, **300–302**
 Jetberry bush (jetbead), 314t. *See also* plants, **309–319**
 Jet fuel
 hepatotoxicity of, 524
 toxic exposures and, 521t
 Jimmyweed, 314t. *See also* plants, **309–319**
 Jimsonweed, 314t. *See also* plants, **309–319**
 Jin bu huan, 217t. *See also* herbal and alternative products, **215–218**
 Jodfenphos (iodofenphos). *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292t
 “Joints” (slang). *See* marijuana, **252–254**
 Jolt. *See* gamma-butyrolactone, 210–213, 211t
Juglans, 317t. *See also* plants, **309–319**
 Juniper (*Juniperus macrospora*), 314t. *See also* plants, **309–319**
 Kadian. *See* morphine, 286–291, 289t, **468–469**
 Kalentra. *See*
 lopinavir, 113t
 ritonavir, 113t
Kalmia spp, 314t, 315t. *See also* plants, **309–319**
 Kanamycin. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 391t
 toxicity of, 82t
 Kaolin. *See also* low-toxicity products, **286**
 accidental exposure to, 287t
Karwinskia humboldtiana (buckthorn/coyotillo). *See also* plants, **309–319**
 neuropathy caused by, 31t
 toxicity of, 311t, 312t
 Kava-kava, 217t, 314t. *See also* herbal and alternative products, **215–218**; plants, **309–319**
 Kayexalate (sodium polystyrene sulfonate)
 as binding agent, 53t
 for hyperkalemia, 38
 KCl (potassium chloride), 492. *See also* potassium, **491–492**
 for barium poisoning, 127
 for hypokalemia, 38, 39, 491–492
 Ketzol. *See* cefazolin, 82t
 Kemadrin. *See* procyclidine, 85t
 Kentucky coffee tree, 314t. *See also* plants, **309–319**
 Kepone. *See also* chlorinated hydrocarbons, **161–162**
 hazard summary for, 583t
 repeat-dose activated charcoal for overdose of, 58t
 toxicity of, 161t
 Keppra. *See* levetiracetam, 86t, 87
 Kerlone. *See* betaxolol, 132t
 Kerosene. *See also* hydrocarbons, **219–221**
 toxicity of, 219, 219t
 in children, 60t
 Ketalar. *See* ketamine, **300–302**
 Ketamine, **300–302**
 in drug-assisted assault, 64t
 dyskinesias caused by, 26t
 pharmacokinetics of, 300–301, 391t
 toxicity of, **300–302**
 Ketene, hazard summary for, 583t
 Ketoacidosis
 alcoholic, 192
 anion gap acidosis caused by, 33, 34t, 192
 ethylene glycol poisoning differentiated from, 192, 197–198
 osmolar gap elevation caused by, 32t, 33
 diabetic
 anion gap acidosis caused by, 33, 34t
 insulin for, 455–456
 osmolar gap elevation caused by, 32t, 33
 Ketones. *See also* hydrocarbons, **219–221**
 toxicity of, 219
 in toxicology screens, interferences and, 44t
 Ketoprofen. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
 pharmacokinetics of, 391t
 toxicity of, 284t
 Ketorolac. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
 pharmacokinetics of, 391t
 toxicity of, 284t
 Khat, 314t. *See also* plants, **309–319**
 KI (iodide/potassium iodide), **456–457**. *See also* iodine, **226–228**
 pharmacology/use of, **456–457**
 for radiation poisoning, 330t, 456–457
 toxicity of, 226
 King snake envenomation, 343t. *See also* snakebites, **343–346**
 Kitacin (IBP). *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292t
 “Kit-kat” (slang). *See* ketamine, **300–302**
 Kitty litter. *See also* nontoxic products, **286**
 accidental exposure to, 287t
 Klonopin. *See* clonazepam, 130t
 Knockout. *See* gamma-butyrolactone, 210–213, 211t
Kochia spp, 312t. *See also* plants, **309–319**
 KOH (potassium hydroxide), hazard summary for, 606t
 Kola nut (*Cola nitida*), toxicity of, 143
 Krait envenomation, 343t. *See also* snakebites, **343–346**
 “Krystal” (slang). *See* phencyclidine, **300–302**
 Kwell. *See* lindane, 161, 161t
 KZn₂(CrO₄)₂(OH) (zinc potassium chromate), hazard summary for, 627t
 L (lewisite)
 burns of eye caused by, dimercaprol (BAL) for, 413–415
 as chemical weapon, 115, 372, 374t, 377. *See also* warfare agents, chemical, **372–378**
 toxicity of, 115, 372, 373, 374t
 Labetalol, **459–460**. *See also* beta-adrenergic blockers, **131–133**
 for hypertension, 18, 459–460
 inamrinone for overdose of, 454–455
 for monoamine oxidase inhibitor overdose, 271
 pharmacokinetics of, 391t
 pharmacology/use of, **459–460**
 toxicity of, 132t, 460
 Laboratory tests
 in diagnosis of poisoning, **31–40**. *See also* toxicology screening, **40–45**
 for occupational toxins, 524–525
 for substances used in drug-assisted assault, 64–65, 64t
Labum anagyroides, 313t. *See also* plants, **309–319**
 Lacrimator agents, as chemical weapons, 372, 373. *See also* warfare agents, chemical, **372–378**
 Lactase. *See also* low-toxicity products, **286**
 accidental exposure to, 287t
 Lactic acidosis, 33, 34t
 antiretroviral drugs causing, 34t, 111, 114
 bicarbonate for, 419–420
 drugs and toxins causing, 34t
 metformin causing, 34t, 93, 95
 osmolar gap elevation caused by, 32t
 Lactulose, hypernatremia caused by, 36t
 Ladyslipper (*Cypripedium* spp), 314t. *See also* plants, **309–319**
 Lady’s slipper (*Pedicularis thymaloides*), 314t. *See also* plants, **309–319**
 Lamictal. *See* lamotrigine, 86t, 87
 Lamivudine. *See also* antiviral and antiretroviral agents, **111–115**
 pharmacokinetics of, 391t
 toxicity of, 112t
 Lamotrigine. *See also* anticonvulsants, **86–87**
 pharmacokinetics of, 391t
 toxicity of, 86t, 87
Lamprolipsis envenomation, 343t. *See also* snakebites, **343–346**

- Lanacane Creme. *See* benzocaine, 75, 75*t*, 76
- Lannate (methomyl). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 587*t*
toxicity of, 293*t*
- Lanolin. *See also* low-toxicity products, **286**
accidental exposure to, 287*t*
- Lanoxicaps. *See* digoxin, 155–157
- Lanoxin. *See* digoxin, 155–157
- Lantadene. *See also* plants, **309–319**
toxicity of, 310*t*
- Lantana (*Lantana camara*), 314*t*. *See also* plants, **309–319**
- Lariam. *See* mefloquine, 165–167
- Larkspur, 314*t*. *See also* plants, **309–319**
- Laryngoscopy, for orotracheal intubation, 6
- Laryngospasm, neuromuscular blocking agents for, 472–475
- Lasix. *See* furosemide, 188*t*
- Latex paint. *See also* low-toxicity products, **286**
accidental exposure to, 287*t*
- Lathyrus odoratus*, 317*t*. *See also* plants, **309–319**
- Latrodectus* (black widow spider) antivenom, 348, **409–410**
pharmacology/use of, **409–410**
- Latrodectus* (black widow spider) envenomation, 346–348
antivenom for, 348, **409–410**
methocarbamol for, 348, 465–466
morphine for, 348, 468–469
during pregnancy, 409
rigidity caused by, 26*t*, 347
- α -Latrotoxin, in black widow spider venom, 346
- Laughing gas. *See* nitrous oxide, **282–283**
- Laurel, 314*t*. *See also* plants, **309–319**
English, 313*t*
mountain, 315*t*
- Laurus nobilis*, 314*t*. *See also* plants, **309–319**
- Lavage, gastric, for gastrointestinal decontamination, 49–50, 51*t*
in caustic and corrosive agent ingestion, 159
in pregnant patient, 59
toxic ingestions and, 516
- Lavender oil. *See also* essential oils, **147–148**
toxicity of, 147*t*
- L-Carnitine
pharmacology/use of, **426–427**
for valproic acid overdose, 364, 426
- L-dopa, monoamine oxidase inhibitor interaction and, 270*t*
- Lead, **238–242**
abdominal x-ray showing, 46*t*
anemia caused by, 239, 524
blood levels of, 240, 241
in bone, x-ray fluorescence measurement of, 240
calcium EDTA for poisoning caused by, 241, 440–442
confusion caused by, 24*t*
delirium caused by, 24*t*
dimercaprol (BAL) for poisoning caused by, 241, 413–415
exposure limits for, 239, 242, 584*t*
hazard summary for, 584*t*
job processes associated with exposure to, 521*t*
neuropathy caused by, 31*t*, 239
penicillamine for poisoning caused by, 241, 484–485
pharmacokinetics of, 238
reproductive disorders associated with exposure to, 239
seizures caused by, 23*t*
succimer (DMSA) for poisoning caused by, 241, 501–503
tetraethyl
hazard summary for, 618*t*
neurotoxic effects of, 523
tetramethyl, hazard summary for, 618*t*
toxicity of, **238–242**
central nervous system effects of, 239, 523
in children, 238, 239, 241–242
hematologic effects of, 239, 524
unithiol (DMP5/2,3-dimercaptopropanol-sulfonic acid) for poisoning caused by, 241, 506–508
urinary excretion of, 240
- Lead arsenate, hazard summary for, 584*t*
- Lead chromate. *See also* chromium, **167–169**
hazard summary for, 584*t*
- Lead colic, **238–242**
- Lead encephalopathy, 239, 241
- “Lead pipe” rigidity, in neuroleptic malignant syndrome, 22
- Left-sided, head down position, in airway management, 1, 4*t*
- Legalon. *See* silibinin, **500–501**
- Leiurus* spp scorpion envenomation, 334–335
- Lente insulin (insulin zinc). *See also* insulin, 93–96, **455–456**
pharmacokinetics of, 391*t*
toxicity of, 94*t*
- Leipota* mushrooms. *See also* mushroom poisoning, **271–275**
toxicity of, 272*t*, 273–275
- Leptophos. *See also* organophosphates and carbamates, **291–295**
toxicity of, 292*t*
- “Lethal factor,” in anthrax toxicity, 368
- Letrozole. *See also* antineoplastic agents, **100–107**
toxicity of, 103*t*
- Leucovorin calcium (folinic acid), **460–461**, 461*t*
for methanol poisoning, 261, 460–461
pharmacology/use of, **460–461**, 461*t*
for trimethoprim poisoning, 81, 460–461
- Leukemia, occupational causes of, 524
- Leukeran. *See* chlorambucil, 101*t*
- Leukopenia, antineoplastic agents causing, 100–106
- Leuprolide. *See also* antineoplastic agents, **100–107**
toxicity of, 103*t*
- Leustatin. *See* cladribine, 102*t*
- Levamisole. *See also* antineoplastic agents, **100–107**
toxicity of, 105*t*
- Levatol. *See* penbutolol, 132*t*
- Levbid. *See* hyoscyamine, 85*t*
- Level of consciousness, decreased (coma and stupor), **19–20**, 19*t*
benzodiazepines causing, 19*t*, 20, 130
flumazenil for treatment of, 20, 131, 416, 446–447
drugs and toxins causing, 19*t*
with immobility, rhabdomyolysis and renal failure caused by, 39*t*
treatment of, 19–20
flumazenil for, 20, 131, 416, 446–447
nalmeferone for, 469–472
naloxone for, 20, 469–472
- Levetiracetam. *See also* anticonvulsants, **86–87**
pharmacokinetics of, 391*t*
toxicity of, 86*t*, 87
- Levobunolol. *See also* beta-adrenergic blockers, **131–133**
pharmacokinetics of, 392*t*
toxicity of, 132*t*
- Levobupivacaine. *See also* anesthetics, local, **74–77**
toxicity of, 75*t*
- Levocarnitine (L-carnitine)
pharmacology/use of, **426–427**
for valproic acid overdose, 364, 426
- Levodopa
confusion caused by, 24*t*
delirium caused by, 24*t*
dyskinesias caused by, 26*t*
hypertension caused by, 18*t*
- Levofloxacin, ventricular arrhythmias caused by, 14*t*
- Levomethadyl, ventricular arrhythmias caused by, 14*t*
- Levophed. *See* norepinephrine, **479–480**
- Levothyroxine. *See also* thyroid hormone, **354–356**
pharmacokinetics of, 392*t*
toxicity of, 356–357, 356*t*
- Levsin. *See* hyoscyamine, 85*t*
- Lewisite
burns of eye caused by, dimercaprol (BAL) for, 413–415
as chemical weapon, 115, 372, 374*t*, 377. *See also* warfare agents, chemical, **372–378**
toxicity of, 115, 372, 373, 374*t*
- Lexapro (escitalopram). *See* citalopram, 88, 88*t*, 89
- Lexxel. *See*
enalapril, 77, 387*t*
felodipine, 144, 145*t*
- L-hyoscyamine. *See also* anticholinergic agents, **84–86**
pharmacokinetics of, 392*t*
toxicity of, 85*t*
- Librax. *See*
chlordiazepoxide, 130*t*
clidinium, 85*t*
- Librium. *See* chlordiazepoxide, 130*t*

- Licorice, wild, 314*t*. *See also* plants, **309–319**
 Licorice root, 314*t*. *See also* plants, **309–319**
 Lidocaine, **462–463**. *See also* antiarrhythmic drugs, **78–81**
 confusion caused by, 24*t*, 462
 delirium caused by, 24*t*
 with epinephrine, toxicity of, 75*t*
 as local anesthetic, 74, 75*t*. *See also* anesthetics, local, **74–77**
 for nasotracheal intubation, 5
 pharmacokinetics of, 392*t*
 pharmacology/use of, 74, **462–463**
 seizures caused by, 23*t*, 462
 toxicity of, 74, 75*t*, 76, 462
 in toxicology screens, 41*t*, 76
 for ventricular arrhythmias, 15, 462–463
 Lighter fluid. *See also* hydrocarbons, **219–221**
 toxicity of, 219
 Ligroin (VM&P naphtha), hazard summary for, 626*t*
Ligustrum spp, 316*t*. *See also* plants, **309–319**
 Lily. *See also* plants, **309–319**
 black, 311*t*
 calla, 312*t*
 wild, 317*t*
 glory, 173. *See also* colchicine, **171–173**
 Lily of the Nile, 314*t*. *See also* plants, **309–319**
 Lily-of-the-valley, 155, 314*t*. *See also* cardiac (digitalis) glycosides, **155–157**; plants, **309–319**
 Lily-of-the-valley bush, 314*t*. *See also* plants, **309–319**
 Limbitrol (amitriptyline with chlordiazepoxide). *See* amitriptyline, 88*t*, 90
 chlordiazepoxide, 130*t*
 Lime (calcium oxide)
 hazard summary for, 545*t*
 hydrated/caustic (calcium hydroxide), hazard summary for, 545*t*
 Lime-A-Way Bathroom/Kitchen Cleaner
 non-phosphate formula (citric acid, hydroxyacetic acid, sulfamic acid). *See* caustic and corrosive agents, **157–159**
 phosphate formula (hydroxyacetic acid, phosphoric acid). *See* caustic and corrosive agents, **157–159**
 Lime nitrogen (calcium cyanamide), hazard summary for, 545*t*
 Lincomycin. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 392*t*
 toxicity of, 82*t*
 Lindane. *See also* chlorinated hydrocarbons, **161–162**
 hazard summary for, 584*t*
 toxicity of, 161, 161*t*
 in children, 60*t*, 161
 volume of distribution of, 55*t*
 Linezolid. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 392*t*
 toxicity of, 82*t*
Lingstrum spp, 312*t*. *See also* plants, **309–319**
 Lionfish envenomation, **242–243**
 Lion's mane jellyfish (*Cyanea capitillata*) envenomation, treatment of, 237
 Liothyronine (triiodothyronine/T₃). *See also* thyroid hormone, **356–357**
 pharmacokinetics of, 392*t*
 toxicity of, 356–357, 356*t*
 Liotrix. *See* triiodothyronine, 356–357
 Lip balm. *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
 Lipodystrophy, antiretroviral agents causing, 111
 Lipstick. *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
 Liquefied petroleum gas (LPG), hazard summary for, 585*t*
 "Liquid E" (slang). *See* gamma-hydroxybutyrate (GHB), 210–213, 211*t*
 "Liquid Ecstasy" (slang). *See* gamma-hydroxybutyrate (GHB), 210–213, 211*t*
 Liquid Gold. *See* 1,4-butanediol, 210–213, 211*t*
 Liquid Libido. *See* gamma-butyrolactone, 210–213, 211*t*
 Liquid Paper Correction Fluid. *See* trichloroethane, **359–361**
 Liquid Plumr. *See*
 caustic and corrosive agents, **157–159**
 hypochlorite, 162–164
 sodium hydroxide, 613*t*
 Liquid soap hand- and dishwashing. *See also* low-toxicity products, **286**
 accidental exposure to, 287*t*
 Liquiprin. *See* acetaminophen, **66–69**
 Lisinopril. *See also* angiotensin blockers/ACE inhibitors, **77–78**
 pharmacokinetics of, 392*t*
 toxicity of, 77
 Lispro. *See also* insulin, 93–96, **455–456**
 pharmacokinetics of, 391*t*
 toxicity of, 94*t*
Listeria monocytogenes, food poisoning/systemic infection caused by (listeriosis), 203, 204*t*, 205. *See also* food poisoning, bacterial, **203–205**
 Listerine Antiseptic Mouthwash. *See* ethanol, **190–193**; **444–446**
 Listermint with Fluoride. *See* fluoride, **200–201**
 Lithium, **243–246**
 atrioventricular (AV) block caused by, 10*t*
 binding agent for, 53*t*
 bradycardia caused by, 10*t*, 244
 coma caused by, 19*t*, 244
 confusion caused by, 24*t*
 delirium caused by, 24*t*, 244
 dyskinesias caused by, 26*t*
 elimination of, 56*t*, 244
 hyperkalemia caused by, 38*t*
 hypernatremia caused by, 36, 36*t*
 hyperthermia caused by, 21*t*, 244
 nephrogenic diabetes insipidus caused by, 36, 244
 pharmacokinetics of, 244, 392*t*
 poor adsorption to activated charcoal and, 52*t*
 quantitative levels/potential interventions and, 45*t*, 244–245
 rhabdomyolysis caused by, 27*t*
 rigidity caused by, 26*t*
 seizures caused by, 23*t*, 244
 stupor caused by, 19*t*, 244
 teratogenic effects of, 59*t*
 toxicity of, **204–206**
 in toxicology screens, interferences and, 44*t*
 volume of distribution of, 55*t*, 56*t*, 244, 392*t*
 Lithium hydride, hazard summary for, 585*t*
 Lithobid. *See* lithium, **243–246**
 Lithonate. *See* lithium, **243–246**
 Lithotabs. *See* lithium, **243–246**
 Little mauve stinger jellyfish (*Pelagia noctiluca*) envenomation, treatment of, 237
 Liver (chicken), monoamine oxidase inhibitor interaction and, 270*t*
 Liver disease. *See* hepatic failure/hepatotoxicity, 40
 Liver transplantation
 for acetaminophen-induced hepatic failure, 68
 for amatoxin mushroom poisoning-induced liver failure, 275
 LMWH (low-molecular-weight heparin), protamine for overdose of, 497–498
 "Loads". *See*
 codeine, 289*t*
 glutethimide, 335*t*, 336
 Lobelia, 314*t*. *See also* plants, **309–319**
 Lobelia spp, 312*t*, 314*t*. *See also* plants, **309–319**

- Mephobarbital. *See also* barbiturates, **124–126**
 pharmacokinetics of, 125*t*, 393*t*
 toxicity of, 125*t*
- Mephosfolan. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
- Mephyton. *See* phytonadione (vitamin K₁), **508–509**
- Mepivacaine. *See also* anesthetics, local, **74–77**
 toxicity of, 75*t*
- Meprobamate. *See also* sedative-hypnotics, **335–337**
 in drug-assisted assault, 64*t*
 elimination of, 56*t*
 pharmacokinetics of, 393*t*
 toxicity of, 335*t*, 336
 in toxicology screens, 41*t*
 volume of distribution of, 56*t*, 393*t*
- Mercaptans
n-butyl, hazard summary for, 544*t*
 ethyl, hazard summary for, 573*t*
 methyl, hazard summary for, 593*t*
 odor caused by, 32*t*
- Mercaptoacetic acid (thioglycolic acid), hazard summary for, 619*t*
- Mercaptophos (demeton). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 557*t*
 pralidoxime (2-PAM)/oximes for poisoning with, 492–494
 toxicity of, 292*t*
- 6-Mercaptopurine. *See also* antineoplastic agents, **100–107**
 teratogenic effects of, 59*t*
 toxicity of, 102*t*
- Mercuric chloride, toxicity of, 254–257
- Mercuric sulfide, teratogenic effects of, 59*t*
- Mercurochrome. *See also* mercury, **254–257**
 toxicity of, 255
- Mercury dimethyl, hazard summary for, 565*t*
- Mercury/mercury vapor, **254–257**, 255*t*
 agitation caused by, 24*t*
 alkyl compounds of, 254
 hazard summary for, 586*t*
 binding agents for, 53*t*, 256–257
 dimercaprol (BAL) for poisoning caused by, 256–257, 413–415
 exposure limits for, 254, 586*t*
 hazard summary for, 586*t*
 hypoxia caused by, 7*t*
 job processes associated with exposure to, 521*t*
 neuropathy caused by, 31*t*
 penicillamine for poisoning caused by, 256, 484–485
 psychosis caused by, 24*t*, 255
 renal failure caused by, 39*t*, 255, 256
 reproductive disorders associated with exposure to, 256
 succimer (DMSA) for poisoning caused by, 256, 257, 501–503
 teratogenic effects of, 59*t*, 256
 in thermometers, accidental exposure to, 288*t*
 toxicity of, **254–257**, 255*t*
 central nervous system effects of, 255, 256, 523
 unithiol (DMPS/2,3-dimercaptopropanol-sulfonic acid) for poisoning caused by, 256, 506–508
- Merremia tuberosa*, 318*t*. *See also* plants, **309–319**
- Mescal bean, 315*t*. *See also* plants, **309–319**
- Mescal button, 315*t*, 316*t*. *See also* plants, **309–319**
- Mescaline (3,4,5-trimethoxyphenethylamine), 248*t*. *See also* hallucinogens, **247–249**
 toxicity of, 248*t*
- Mesityl oxide, hazard summary for, 586*t*
- Meso-2,3-dimercaptosuccinic acid (succimer/DMSA), **501–503**
 for arsenic poisoning, 118, 501–503
 for arsine gas poisoning, 121
 for lead poisoning, 241, 501–503
 for mercury poisoning, 256, 257, 501–503
 pharmacology/use of, **501–503**
- Mesoridazine. *See also* antipsychotic drugs, **107–109**
 pharmacokinetics of, 393*t*
 toxicity of, 107*t*
 ventricular arrhythmias caused by, 14*t*
- Mesothelioma, asbestos exposure and, 122
- Metabisulfite, sodium, hazard summary for, 613*t*
- Metabolic acidemia, treatment of, 34
- bicarbonate for, 34, 419–420
- Metabolic acidosis
 anion gap, 33–34, 34*t*
 drugs and toxins causing, 34*t*
 metformin causing, 34*t*, 93, 95
 osmolar gap with, 32, 33
 antiretroviral agents causing, 34*t*, 111, 114
 bicarbonate for, 419–420
- Metacrate (MTMC). *See also* organophosphates and carbamates, **291–295**
 toxicity of, 293*t*
- Metal degreasing, toxic exposures and, 521*t*
- Metaldehyde, **258**
 anion gap acidosis caused by, 34*t*, 258
 osmolar gap elevation caused by, 32*t*, 258

- pharmacokinetics of, 258, 393t
seizures caused by, 23t, 258
toxicity of, **258**
- Metal fume fever, **259, 520**
hyperthermia caused by, 21t
hypoxia caused by, 7t
- Metallic foreign bodies, abdominal x-ray showing, 46t
- Metal plating, toxic exposures and, 521t
- Metal work, toxic exposures and, 521t
- Metaproterenol. *See also* beta-adrenergic agents, **131–133**
pharmacokinetics of, 393t
propranolol for overdose of, 496–497
toxicity of, 134t
- Metaraminol, monoamine oxidase inhibitor interaction and, 270t
- Metaxalone, pharmacokinetics of, 393t
- Metformin. *See also* antidiabetic (hypoglycemic) agents, **93–96**
anion gap/lactic acidosis caused by, 34t, 93, 95
elimination of, 56t
pharmacokinetics of, 393t
toxicity of, 93, 94t, 96
- Methacrylate
job processes associated with exposure to, 521t
methyl, hazard summary for, 593t
- Methacrylic acid, hazard summary for, 586t
- Methacrylonitrile (methacrylonitrile), hazard summary for, 588t
- Methadone, 289t. *See also* opiates/opioids, **286–291**
pharmacokinetics of, 289, 393t
toxicity of, 289t
in toxicology screens, 41t
interferences and, 44t
withdrawal from, in neonates, 62–63
- Methamidophos. *See also* organophosphates and carbamates, **291–295**
toxicity of, 292t
- Methamphetamine, 72, 73t. *See also* amphetamines, **72–74**
pharmacokinetics of, 393t
toxicity of, 72, 73t
- Methanal (formaldehyde), **207–209**. *See also* caustic and corrosive agents, **157–159**; gases, irritant, **213–215**
anion gap acidosis caused by, 34t, 158t, 208
exposure limits for, 208, 214t, 575t
hazard summary for, 575t
methanol intoxication and, 208, 260–261
toxicity of, 158t, **207–209**, 214t
- Methanamide (formamide), hazard summary for, 575t
- Methane, hypoxia caused by, 7t
- Methane arsonates. *See also* arsenic, **115–119**
toxicity of, 115
- Methanol (methyl alcohol), **260–261**
anion gap elevation/acidosis caused by, 32, 33, 34t, 260, 261
bicarbonate for poisoning caused by, 419–420
elimination of, 56t, 260
estimation of level of from osmolar gap, 33t
ethanol for poisoning with, 261, 444–446, 446t
exposure limits for, 260, 588t
folic acid for poisoning caused by, 261, 447–448
fomepizole for poisoning caused by, 261, 445, 448–449
formaldehyde/formic acid and, 208, 260–261
in formalin, 208
hazard summary for, 588t
leucovorin for poisoning caused by, 261, 460–461
osmolar gap elevation caused by, 32, 32t, 33, 260
pharmacokinetics of, 260
quantitative levels/potential interventions and, 45t, 260
seizures caused by, 23t, 260
toxicity of, **260–261**
in toxicology screens, 41t
volume of distribution of, 56t
- Methanethine. *See also* anticholinergic agents, **84–86**
toxicity of, 85t
- Methaqualone. *See also* sedative-hypnotics, **335–337**
elimination of, 56t
pharmacokinetics of, 393t
rigidity caused by, 26t
toxicity of, 335t, 336
- in toxicology screens, 41t
volume of distribution of, 56t, 393t
- Methazolamide. *See also* diuretics, **187–189**
pharmacokinetics of, 393t
toxicity of, 188t
- Methdilazine. *See also* antihistamines, **96–98**
toxicity of, 97t
- Methemoglobin/methemoglobinemia, **261–263**, 262t
agents causing, 261, 262t
benzocaine or prilocaine, 75, 76
bromates, 139
chlorates, 160
dapsone, 81, 179–180, 180
nitrites, 279
phenols, 302, 303
potassium permanganate, 110, 111, 158t
coma in, 19t, 262
hyperbaric oxygen therapy for, 263
hypoxia in, 7t, 8, 262
methylene blue for treatment of, 263, 466–467
occupational causes of, 261, 524
quantitative levels/potential interventions and, 45t, 262, 263
smoke inhalation and, 342
stupor in, 19t, 262
tachycardia in, 13t
in toxicology screens, interferences and, 44t
- Methicillin. *See also* antibacterial agents, **81–84**
pharmacokinetics of, 393t
toxicity of, 83t
- Methidathion. *See also* organophosphates and carbamates, **291–295**
toxicity of, 292t
- Methiocarb. *See also* organophosphates and carbamates, **291–295**
toxicity of, 293t
- Methocarbamol, **465–466**. *See also* skeletal muscle relaxants, **339–341**
for *Latrodectus* spider bites, 348, 465–466
pharmacokinetics of, 394t
pharmacology/use of, **465–466**
toxicity of, 340t, 465–466
- Methohexital. *See also* barbiturates, **124–126**
pharmacokinetics of, 125t, 394t
toxicity of, 125, 125t
- Methomyl. *See also* organophosphates and carbamates, **291–295**
hazard summary for, 587t
toxicity of, 293t
- Methotrexate. *See also* antineoplastic agents, **100–107**
elimination of, 56t
leucovorin calcium for overdose of, 460–461, 461t
teratogenic effects of, 59t
toxicity of, 102t
volume of distribution of, 56t
- Methoxamine, hypertension caused by, 18t
- p-Methoxyamphetamine (PMA), 248t. *See also* hallucinogens, **247–249**
toxicity of, 248t, 249
- o-Methoxyaniline (o-anisidine), hazard summary for, 537t
- Methoxychlor. *See also* chlorinated hydrocarbons, **161–162**
hazard summary for, 587t
toxicity of, 161t
- 2-Methoxyethanol (EGME/ethylene glycol monomethyl ether/methyl cellosolve). *See also* glycols, **194–198**
hazard summary for, 587t
hematologic disorders caused by, 524
toxicity of, 196t
- 2-Methoxyethyl acetate, hazard summary for, 587t
- 3-Methoxy-4,5-methylene-dioxyallylbenzene (myristicin/nutmeg), 248t, 315t. *See also* hallucinogens, **247–249**; plants, **309–319**
- 2,2-bis(p-Methoxyphenol)-1,1,1-trichloroethane (methoxychlor). *See also* chlorinated hydrocarbons, **161–162**
hazard summary for, 587t
toxicity of, 161t
- 1-Methoxy-2-propanol (propylene glycol monomethyl ether), hazard summary for, 608t

- Methscopolamine. *See also* anticholinergic agents, **84–86**
 pharmacokinetics of, 394*t*
 toxicity of, 85*t*
- Methyclothiazide. *See also* diuretics, **187–189**
 pharmacokinetics of, 394*t*
 toxicity of, 188*t*
- Methyl acetate, hazard summary for, 587*t*
- Methyl acetylene, hazard summary for, 587*t*
- Methyl acrylate, hazard summary for, 588*t*
- Methylacrylonitrile, hazard summary for, 588*t*
- Methylal, hazard summary for, 588*t*
- Methyl alcohol (methanol), **260–261**
 anion gap elevation/acidosis caused by, 32, 33, 34*t*, 260, 261
 bicarbonate for poisoning caused by, 419–420
 elimination of, 56*t*, 260
 estimation of level of from osmolar gap, 33*t*
 ethanol for poisoning with, 261, 444–446, 446*t*
 exposure limits for, 260, 588*t*
 folic acid for poisoning caused by, 261, 447–448
 fomepizole for poisoning caused by, 261, 445, 448–449
 formaldehyde/formic acid and, 208, 260–261
 in formalin, 208
 hazard summary for, 588*t*
 leucovorin for poisoning caused by, 261, 460–461
 osmolar gap elevation caused by, 32, 32*t*, 33, 260
 pharmacokinetics of, 260
 quantitative levels/potential interventions and, 45*t*, 260
 seizures caused by, 23*t*, 260
 toxicity of, **260–261**
 in toxicology screens, 41*t*
 volume of distribution of, 56*t*
- Methylamine, hazard summary for, 588*t*
- Methyl-*n*-amyl ketone, hazard summary for, 588*t*
- 2-Methylaniline (*o*-toluidine), hazard summary for, 621*t*
- 3-Methylaniline (*m*-toluidine), hazard summary for, 621*t*
- 4-Methylaniline (*p*-toluidine), hazard summary for, 621*t*
- N*-Methylaniline, hazard summary for, 589*t*
- 2-Methylaziridine (propylene imine), hazard summary for, 608*t*
- Methylbenzene (toluene), **357–359**
 exposure limits for, 358, 620*t*
 hazard summary for, 620*t*
 hypokalemia caused by, 38*t*
 kinetics of, 358
 toxicity of, **357–359**
- n*-Methyl-1(1,3-benzodioxol-5-yl)-2-butanamine (MBDB), 248*t*. *See also* hallucinogens, **247–249**
 toxicity of, 248*t*
- Methyl bromide, **263–265**
 exposure limits for, 264, 589*t*
 hazard summary for, 589*t*
 job processes associated with exposure to, 521*t*
 pharmacokinetics of, 264
 seizures caused by, 23*t*, 264
 toxicity of, **263–265**
 central nervous system effects and, 264, 523
- 3-Methyl-butanol (isoamyl alcohol), hazard summary for, 581*t*
- 3-Methyl butyl acetate (isoamyl acetate), hazard summary for, 581*t*
- α -Methylbutyl acetate (*sec*-amyl acetate), hazard summary for, 537*t*
- Methyl(1-(butylcarbamoyl)-2-benzimidazolecarbamate (benomyl), hazard summary for, 539*t*
- Methyl *n*-butyl ketone
 hazard summary for, 589*t*
 neuropathy caused by, 31*t*
- Methyl cellosolve (ethylene glycol monomethyl ether/2-methoxyethanol/EGME). *See also* glycols, **194–198**
 hazard summary for, 587*t*
 hematologic disorders caused by, 524
 toxicity of, 196*t*
- Methyl cellosolve acetate (2-methoxyethyl acetate), hazard summary for, 587*t*
- Methyl chloride, hazard summary for, 589*t*
- Methyl chloroform (1,1,1-trichloroethane)
 exposure limits for, 359–360, 622*t*
 hazard summary for, 622*t*
 toxicity of, 359–361
- Methyl chloromethyl ether (chloromethyl methyl ether/CMME), hazard summary for, 550*t*
- Methyl cyanide (acetonitrile). *See also* cyanide, **177–179**
 hazard summary for, 533*t*
 job processes associated with exposure to, 521*t*
 toxicity of, 177
- Methyl-2-cyanoacrylate, hazard summary for, 589*t*
- Methylcyclohexane, hazard summary for, 590*t*
- o*-Methylcyclohexanone, hazard summary for, 590*t*
- Methylcyclopentadienyl manganese tricarbonyl (MMT), toxicity of, 251–252
- Methyl demeton, hazard summary for, 590*t*
- 2-Methyl-4,6-dinitrophenol (dinitro-*o*-cresol), hazard summary for, 565*t*
- Methyldopa, 16*t*, 169–171
 coma caused by, 19*t*
 monoamine oxidase inhibitor interaction and, 270*t*
 pharmacokinetics of, 394*t*
 stupor caused by, 19*t*
 toxicity of, 169–171
- 4,4'-Methylene-bis(2-chloroaniline), hazard summary for, 590*t*
- Methylene bis(4-cyclohexylisocyanate), hazard summary for, 590*t*
- Methylene bisphenyl isocyanate, hazard summary for, 590*t*
- Methylene blue, **466–467**
 for methemoglobinemia, 263, 466–467
 in bromate poisoning, 139
 in chlorate poisoning, 160
 in dapsone overdose, 81, 180, 180–181
 in nitrate/nitrite overdose, 280
 in nitrogen oxide poisoning, 281
 in pentachlorophenol poisoning, 298
 in phenol poisoning, 303
 in phosphate containing detergent ingestion, 182
 in smoke inhalation, 342
 pharmacology/use of, **466–467**
- Methylene chloride (dichloromethane), **265–267**
 exposure limits for, 266, 591*t*
 hazard summary for, 591*t*
 job processes associated with exposure to, 521*t*
 toxicity of, 158*t*, **265–267**
- 4,4'-Methylene dianiline, hazard summary for, 591*t*
- Methylene dichloride (methylene chloride/dichloromethane), **265–267**
 exposure limits for, 266, 591*t*
 hazard summary for, 591*t*
 job processes associated with exposure to, 521*t*
 toxicity of, 158*t*, **265–267**
- Methylene diisocyanate (MDI), toxicity of, **232–233**
- 3,4-Methylenedioxy-amphetamine (MDA). *See also* amphetamines, **72–74**; hallucinogens, **247–249**
 toxicity of, 248*t*, 249
- 3,4-Methylenedioxymethamphetamine (MDMA/ecstasy), 72, 248*t*. *See also* amphetamines, **72–74**; hallucinogens, **247–249**
 hyperthermia caused by, 21*t*
 monoamine oxidase inhibitor interaction and, 270*t*
 seizures caused by, 23*t*
 toxicity of, 72, 248*t*
- 3,4-Methylene-*n*-ethylamphetamine (MDE/Eve), 248*t*. *See also* amphetamines, **72–74**; hallucinogens, **247–249**
 toxicity of, 248*t*
- Methyl ethyl ketone, hazard summary for, 591*t*
- Methyl ethyl ketone peroxide, hazard summary for, 591*t*
- Methyl formate, hazard summary for, 591*t*
- 5-Methyl-3-heptanone (ethyl amyl ketone), hazard summary for, 570*t*
- 5-Methyl-2-hexanone (methyl isoamyl ketone), hazard summary for, 592*t*
- Methylhydrazine (monomethylhydrazine)
 hazard summary for, 592*t*
 hepatotoxicity of, 524
 job processes associated with exposure to, 521*t*
 poisoning with mushrooms containing, 272*t*
 treatment of, 273
 pyridoxine for, 273, 499–500
- Methylin. *See* methylphenidate, 72, 73*t*
- Methyl iodide, hazard summary for, 592*t*

- Methyl isoamyl ketone, hazard summary for, 592*t*
 Methyl isobutyl ketone, hazard summary for, 592*t*
 Methyl isocyanate, hazard summary for, 593*t*
 Methyl mercaptan, hazard summary for, 593*t*
 Methylmercury. *See also* mercury, **254–257**
 acetylcysteine for poisoning caused by, 257, 405–407
 exposure limits for, 255
 teratogenic effects of, 59*t*, 256
 toxicity of, 254–257
 central nervous system effects of, 256, 523
 Methyl methacrylate, hazard summary for, 593*t*
 S-Methyl-N[(methylcarbamoyl)oxy] thioacetimidate (methomyl). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 587*t*
 toxicity of, 293*t*
 Methyl parathion, hazard summary for, 593*t*
 2-Methyl-2,4-pentanediol (hexylene glycol), hazard summary for, 578*t*
 4-Methyl-2-pentanone (methyl isobutyl ketone), hazard summary for, 592*t*
 4-Methyl-3-penten-2-one (mesityl oxide), hazard summary for, 586*t*
 Methylphenidate, 72, 73*t*. *See also* amphetamines, **72–74**
 monoamine oxidase inhibitor interaction and, 270*t*
 pharmacokinetics of, 394*t*
 toxicity of, 72, 73*t*
 Methylphenol (cresol). *See also* phenols, **302–303**
 hazard summary for, 554*t*
 toxicity of, 302
 4-*tert*-butyl-2-chlorophenyl *N*-methyl *O*-Methylphosphoramidate (crufomate), hazard summary for, 554*t*
 Methylprednisolone, for anaphylactic/anaphylactoid reactions, 28*t*
 2-Methyl-pro-penenitrile (methylacrylonitrile), hazard summary for, 588*t*
 2-Methylpropenoic acid (methacrylic acid), hazard summary for, 586*t*
 2-Methyl-1 propanol (isobutyl alcohol), hazard summary for, 582*t*
 2-Methylpropyl acetate (isobutyl acetate), hazard summary for, 581*t*
 Methyl propyl ketone, hazard summary for, 593*t*
 4-Methylpyrazole (4-MP/fomepizole), **448–449**
 for ethylene glycol poisoning, 198, 445, 448–449
 for methanol poisoning, 261, 445, 448–449
 pharmacology/use of, **448–449**
 Methyl salicylate. *See also* salicylates, **331–333**
 odor caused by, 32*t*
 toxicity of, 331
 in children, 60*t*
 Methyl silicate, hazard summary for, 593*t*
 Methylstyrene (vinyl toluene), hazard summary for, 626*t*
 α-Methylstyrene, hazard summary for, 594*t*
 Methyl tert butyl ether, hazard summary for, 594*t*
 Methyl trithion. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
 Methypyrrol. *See also* sedative-hypnotics, **335–337**
 pharmacokinetics of, 394*t*
 toxicity of, 335*t*
 Methysergide, 189–190
 pharmacokinetics of, 394*t*
 for serotonin syndrome, 89, 271
 toxicity of, 189–190
 Metoclopramide, **467–468**
 for acetaminophen-induced vomiting, 68, 467–468
 dystonia caused by, 26*t*
 pharmacology/use of, **467–468**
 Metolazone. *See also* diuretics, **187–189**
 pharmacokinetics of, 394*t*
 toxicity of, 188*t*
 Metoprolol. *See also* beta-adrenergic blockers, **131–133**
 pharmacokinetics of, 394*t*
 for pseudoephedrine/ephedrine/decongestant-induced arrhythmias, 322
 toxicity of, 132*t*
 Metribuzin, hazard summary for, 594*t*
 MetroCream. *See* metronidazole, 82*t*
 MetroGel. *See* metronidazole, 82*t*
 Metronidazole. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 394*t*
 toxicity of, 82*t*
 Mevinphos. *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 594*t*
 toxicity of, 292*t*
 Mexacarbate. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 293*t*
 Mexiletine. *See also* antiarrhythmic drugs, **78–81**
 pharmacokinetics of, 394*t*
 toxicity of, 79–80, 79*t*
 Mexilit. *See* mexiletine, 79–80, 79*t*
 Mezlin. *See* mezlocillin, 83*t*
 Mezlocillin. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 394*t*
 toxicity of, 83*t*
 Mg (magnesium), **250–251, 463–464**
 for beta-adrenergic blocker overdose, 132*t*
 osmolar gap elevation caused by, 32*t*
 pharmacokinetics of, 250, 392*t*
 pharmacology/use of, **463–464**
 toxicity of, **250–251, 463**
 Mibefradil. *See also* calcium antagonists, **144–147**
 pharmacokinetics of, 394*t*
 toxicity of, 144, 145, 145*t*
 withdrawal of from market, 145
 MIC (methyl isocyanate), hazard summary for, 593*t*
 Mica, hazard summary for, 594*t*
 Miconazole. *See also* low-toxicity products, **286**
 accidental exposure to, 287*t*
 Microelectronics chip industry, toxic exposures and, 521*t*
 Micronase. *See* glyburide, 93, 94*t*
 Micrurus (coral snake) envenomation, 343*t*. *See also* snakebites, **343–346**
 antivenom for, 345, **410–411**
 Micrurus fulvius (coral snake) antivenom, 345, **410–411**
 pharmacology/use of, **410–411**
 Midamor. *See* amiloride, 188*t*
 Midazolam, **415–418**. *See also* benzodiazepines, **129–131, 415–418**
 for agitation/delirium/psychosis, 25, 415–418
 for dyskinesia, 26
 for hyperthermia, 22
 pharmacokinetics of, 394*t*, 416
 pharmacology/use of, **415–418**
 for seizures, 24, 415–418
 for strychnine poisoning, 349
 for tetanus, 352
 toxicity of, 129, 130, 130*t*, 416
 Midol. *See*
 aspirin, 331–333
 caffeine, **142–144**
 ephedrine, **320–322**
 Miglitol. *See also* antidiabetic (hypoglycemic) agents, **93–96**
 pharmacokinetics of, 394*t*
 toxicity of, 94*t*
 Milk, as binding agent, 53*t*
 Milk of magnesia. *See* magnesium, **250–251, 463–464**
 Milk thistle (silibinin/*Silybum marianum*), 217*t*, **500–501**.
 See also herbal and alternative products, **215–218**
 for amatoxin mushroom poisoning, 275, 500–501
 pharmacology/use of, **500–501**
 toxicity of, 217*t*
 Milkweed, 315*t*. *See also* plants, **309–319**
 Miltown. *See* meprobamate, 335*t*, 336
 Mineral acids
 anion gap acidosis caused by, 34*t*
 corrosive injury caused by, 157–159
 poor adsorption to activated charcoal and, 52*t*
 Mineral oil, for chemical exposures to skin, 47*t*
 Mineral seal oil. *See also* hydrocarbons, **219–221**
 toxicity of, 219*t*
 Mineral spirits (Stoddard solvent), hazard summary for, 613*t*
 Minipress. *See* prazosin, 365–366
 Minizide. *See* polythiazide, 188*t*
 Minocin. *See* minocycline, 83*t*

- Minocycline. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 394*t*
 toxicity of, 83*t*
- Minoxidil
 hypotension caused by, 16*t*
 pharmacokinetics of, 394*t*
 toxicity of, 365–366
- Miosis, selected causes of, 30, 30*t*
- MIPC (isoprocarb). *See also* organophosphates and carbamates, **291–295**
 toxicity of, 293*t*
- Mirabilis jalapa*, 313*t*. *See also* plants, **309–319**
- Miraculous Insecticide Chalk. *See* deltamethrin, 323
- Mirex. *See also* chlorinated hydrocarbons, **161–162**
 toxicity of, 161*t*
- Mirtazapine, 88. *See also* antidepressants, noncyclic, **88–90**
 pharmacokinetics of, 394*t*
 toxicity of, 88, 88*t*, 89
- Mistletoe. *See also* plants, **309–319**
 American, 315*t*
 European, 315*t*
- Mithracin. *See* mithramycin (plicamycin), 102*t*, 106
- Mithramycin (plicamycin). *See also* antineoplastic agents, **100–107**
 extravasation of, 106
 toxicity of, 102*t*, 106
- Mitomycin-C. *See also* antineoplastic agents, **100–107**
 extravasation of, 106
 toxicity of, 102*t*, 106
- Mitotane. *See also* antineoplastic agents, **100–107**
 toxicity of, 105*t*
- Mitotic inhibitors. *See also* antineoplastic agents, **100–107**
 toxicity of, 100, 103–104*t*
- Mitoxantrone. *See also* antineoplastic agents, **100–107**
 extravasation of, 106
 toxicity of, 102*t*, 106
- Mivacron. *See* mivacurium, 473*t*, 475
- Mivacurium. *See also* neuromuscular blocking agents, **472–475**
 for orotracheal intubation, 472–475
 pharmacology/use of, 473*t*, 475
- Mixed alpha- and beta-adrenergic syndrome, 29, 29*t*
- Mixed cholinergic syndrome, 29*t*, 30
- MMT (methylcyclopentadienyl manganese tricarbonyl), toxicity of, 251–252
- Moban. *See* molindone, 107*t*
- MOCA (4,4'-methylene-bis[2-chloroaniline]), hazard summary for, 590*t*
- Mock azalea, 315*t*. *See also* plants, **309–319**
- Moclobemide. *See also* monoamine oxidase inhibitors, **269–271**
 pharmacokinetics of, 394*t*
 toxicity of, 269–271
- Moexipril
 pharmacokinetics of, 395*t*
 ventricular arrhythmias caused by, 14*t*
- Mojave rattlesnake envenomation, 344, 345. *See also* snakebites, **343–346**
 antivenom for, 345, 408
- Molds, toxicity of, **267–269**
- Molindone. *See also* antipsychotic drugs, **107–109**
 toxicity of, 107*t*
- Monkshood, 315*t*. *See also* plants, **309–319**
- Monoacetin (glyceryl monoacetate), in fluoroacetate poisoning, 202
- Monoamine oxidase inhibitors (MAOIs), **269–271**, 270*t*
 drug/food interactions and, 270, 270*t*
 with dextromethorphan, 183, 270*t*
 hypertension caused by, 18*t*, 270
 phentolamine for, 487–488
 hyperthermia caused by, 21*t*, 22, 270
 mydriasis caused by, 30*t*
 neuromuscular blocking agents for overdose of, 472–475
 rhabdomyolysis caused by, 27*t*
 rigidity caused by, 26*t*
 serotonin syndrome caused by, 22, 89, 270, 271
 toxicity of, **269–271**, 270*t*
- Monochlorobenzene (chlorobenzene), hazard summary for, 549*t*
- Monoclonal antibodies, as antineoplastic agents. *See also* antineoplastic agents **100–107**
 toxicity of, 100, 104*t*
- Monocrotophos. *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 595*t*
 toxicity of, 292*t*
- Monofluorophosphate, sodium, 200*t*. *See also* fluoride, **200–201**
- Monomethylhydrazine (methylhydrazine)
 hazard summary for, 592*t*
 hepatotoxicity of, 524
 job processes associated with exposure to, 521*t*
 poisoning with mushrooms containing, 272*t*
 treatment of, 273
- pyridoxine for, 273, 499–500
- Monopril. *See* fosinopril, 389*t*
- Monstera friedrichsthali*, 317*t*. *See also* plants, **309–319**
- Moonseed, 315*t*. *See also* plants, **309–319**
 Carolina, 315*t*
- Mop and Glo. *See* ammonia, **70–72**, 214, 214*t*
- Moraine. *See also* tricyclic antidepressants, **90–93**
 toxicity of, 81
- Moricizine. *See also* antiarrhythmic drugs, **78–81**
 pharmacokinetics of, 395*t*
 toxicity of, 79*t*, 80
- Mormon tea, 315*t*. *See also* plants, **309–319**
- Morning glory, 315*t*. *See also* plants, **309–319**
- Morphine, 286–291, 289*t*, **468–469**. *See also* opiates/opioids, **286–291**
 for *Latrodectus* spider bites, 348, 468–469
 pharmacokinetics of, 395*t*
 pharmacology/use of, **468–469**
 for strychnine poisoning, 349
 for tetanus, 352
 toxicity of, 286–291, 289*t*, 469
 in toxicology screens, 41*t*
 interferences and, 44*t*
- Morpholine, hazard summary for, 595*t*
- Mothballs, drugs or toxins causing odor of, 32*t*
- Motofen (difenoxin and atropine), 246–247
- Motor oil. *See also* hydrocarbons, **219–221**
 toxicity of, 219*t*
- Motrin. *See* ibuprofen, 284*t*, 285
- Mountain laurel, 315*t*. *See also* plants, **309–319**
- Moxalactam. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 395*t*
 toxicity of, 82*t*
- Moxifloxacin, ventricular arrhythmias caused by, 14*t*
- 4-MP (fomepizole), **448–449**
 for ethylene glycol poisoning, 198, 445, 448–449
 for methanol poisoning, 261, 445, 448–449
 pharmacology/use of, **448–449**
- MPMC (meobal). *See also* organophosphates and carbamates, **291–295**
 toxicity of, 293*t*
- Mr. Muscle Aerosol Oven Cleaner. *See* caustic and corrosive agents, **157–159**
 ethylene glycol monobutyl ether (EGBE/2-butoxyethanol/butyl cellosolve), 196*t*, 432
- MS Contin. *See* morphine, 286–291, 289*t*, **468–469**
- MSDSs (Material Safety Data Sheets)
 for information about substance involved in hazardous materials incident, 512
 for information about substance involved in occupational exposure, 520
- MSIR. *See* morphine, 286–291, 289*t*, **468–469**
- MTBE (methyl tert butyl ether), hazard summary for, 594*t*
- MTMC (metacrate). *See also* organophosphates and carbamates, **291–295**
 toxicity of, 293*t*
- Mucomyst. *See* acetylcysteine, **405–407**
- Mucosil. *See* acetylcysteine, **405–407**
- Mum (chrysanthemum). *See also* plants, **309–319**
 pyrethrins derived from, 322
 toxicity of, 312*t*
- Munchausen's syndrome by proxy, 61
- ipeac poisoning and, 228, 229

- Muriatic acid (hydrogen chloride). *See also* gases, irritant, **213–215**
 exposure limits for, 214*t*, 579*t*
 hazard summary for, 579*t*
 toxicity of, 214*t*
- Murine Plus Eye Drops. *See* tetrahydrozoline, 169–171
- Muscarine, poisoning with mushrooms containing, 272*t*, 273. *See also* mushroom poisoning, **271–275**
- Muscarinic cholinergic syndrome, 29*t*, 30
- Muscimol, poisoning with mushrooms containing, 272*t*, 273. *See also* mushroom poisoning, **271–275**
- Muscle relaxants, **339–341**, 340*t*
 benzodiazepines as, 415–418
 toxicity of, **339–341**
- Muscle rigidity. *See* rigidity, **25–26**, 26*t*
- Muscle spasm
 drugs for treatment of
 benzodiazepines, 415–418
 methocarbamol, 465–466
 toxicity of, **339–341**, 340*t*
 in strychnine poisoning, 349–350
 in tetanus, 351, 352
- Musculoskeletal disorders, occupational causes of, 522, 522*t*
- Mushroom poisoning, **271–275**, 272*t*
 acetylcysteine for, 275, 405–407
 amatoxin-type, 272*t*, **273–275**
 atropine and glycopyrrolate for, 412–413
 hepatic failure caused by, 40*t*, 272*t*, 274
 hypotension caused by, 16*t*
 pyridoxine for, 499–500
 renal failure caused by, 39*t*
 rhabdomyolysis caused by, 27*t*
 silibinin (milk thistle) for, 275, 500–501
 tachycardia caused by, 13*t*
- Mustards
 as chemical weapons, 372, 374*t*. *See also* warfare agents, chemical, **372–378**
 toxicity of, 372, 374*t*
- Mustine, teratogenic effects of, 59*t*
- Mycotoxins, 267–268. *See also* molds, **267–269**
 T-2, as biological weapons, 370*t*. *See also* warfare agents, biological, **367–372**
 toxicity of, 267–268
- Mydriasis, selected causes of, 30, 30*t*
- Mylanta. *See* magnesium, **250–251**, **463–464**
- Mylar balloons. *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
- Myleran. *See* busulfan, 101*t*
- Myocardial infarction
 carbon monoxide exposure and, 523
 cocaine abuse and, 172
 nitrate exposure and, 279
 pseudoephedrine/ephedrine/decongestants causing, 321
- Myristica fragrans* (nutmeg), 248*t*, 315*t*. *See also* hallucinogens, **247–249**; plants, **309–319**
- Myristica oil. *See also* essential oils, **147–148**
 toxicity of, 147*t*
- Myristicin (3-methoxy-4,5-methylene-dioxallylbenzene/nutmeg), 248*t*, 315*t*. *See also* hallucinogens, **247–249**; plants, **309–319**
- Mysoline. *See* primidone, 124–125
- Myxedema, hypoglycemia in, 35*t*
- Nabumetone. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
 pharmacokinetics of, 395*t*
 toxicity of, 284*t*
- N*-acetylcysteine (NAC), **405–407**
 for acetaminophen overdose, 68–69, 405–407
 anaphylactoid reaction caused by, 28*t*
 for carbon tetrachloride poisoning, 155, 405–407
 for chloroform poisoning, 155, 405–407
 for chromium poisoning, 168, 405–407
 for methyl bromide poisoning, 265
 for methylmercury poisoning, 257, 405–407
 for pennyroyal oil ingestion, 148, 405–407
 pharmacology/use of, **405–407**
- N*-acetylprocainamide (NAPA), 324*t*, 325. *See also* procainamide, **324–326**
 elimination of, 56*t*
 toxicity of, 324–326, 324*t*
- Nadolol. *See also* beta-adrenergic blockers, **131–133**
 elimination of, 56*t*
 pharmacokinetics of, 395*t*
 repeat-dose activated charcoal for overdose of, 58*t*
 toxicity of, 132*t*
 volume of distribution of, 56*t*, 395*t*
- Nafcillin. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 395*t*
 toxicity of, 83*t*
 warfarin interaction and, 379*t*
- NaHSO₃ (sodium bisulfite), hazard summary for, 612*t*
- Nail polish (dry). *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
- Nails
 arsenic concentrations in, 117, 118
 artificial, toxic exposures associated with application and removal of, 521*t*
- Naja* envenomation, 343*t*. *See also* snakebites, **343–346**
- Naked lady, 315*t*. *See also* plants, **309–319**
- Nalbuphine, 289*t*. *See also* opiates/opioids, **286–291**
 pharmacokinetics of, 395*t*
 toxicity of, 289*t*
- Naled (1,2-dibromo-2,2-dichloroethyl dimethyl phosphate). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 558*t*
 toxicity of, 292*t*
- Nalfon. *See* fenoprofen, 284*t*, 285
- Nalidixic acid. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 395*t*
 toxicity of, 82*t*
- Nalmefene, **469–472**, 470*t*
 for opiate/opioid overdose, 290, 469–472
 pharmacology/use of, **469–472**, 470*t*
- Naloxone, 1, **469–472**, 470*t*
 for clonidine overdose, 170, 469–472
 for coma and stupor, 20, 469–472
 for dextromethorphan overdose, 184
 for ethanol toxicity, 192, 469–472
 for Lomotil overdose, 246
 for opiate/opioid overdose, 290, 469–472
 pharmacokinetics of, 395*t*, 470*t*
 pharmacology/use of, **469–472**, 470*t*
 for seizures, 23
 for valproic acid overdose, 364, 469–472
- Naltrexone, 469
 pharmacokinetics of, 395*t*
- NaN₃ (sodium azide), **122–124**
 anion gap acidosis caused by, 34*t*
 coma caused by, 19*t*
 hazard summary for, 612*t*
 stupor caused by, 19*t*
 toxicity of, **122–124**
- NaOH (sodium hydroxide), hazard summary for, 613*t*
- NAPA (procainamide *N*-acetylprocainamide), 324*t*, 325. *See also* procainamide, **324–326**
 elimination of, 56*t*
 toxicity of, 324–326, 324*t*
- Naphtha, varnish makers' and printers' (VM&P), hazard summary for, 626*t*
- Naphthalene, **275–277**
 hazard summary for, 595*t*
 odor caused by, 32*t*, 276
 pharmacokinetics of, 276
 renal failure caused by, 39*t*
 toxicity of, **275–277**
- β-Naphthylamine, hazard summary for, 595*t*
- 1-Naphthyl *N*-methylcarbamate (carbaryl). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 546*t*
 pralidoxime (2-PAM)/oximes for poisoning with, 492–494
 toxicity of, 293*t*
- α-Naphthylthiourea (ANTU), hazard summary for, 538*t*
- Naprosyn. *See* naproxen, 284*t*

- Naproxen. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
 pharmacokinetics of, 285, 395*t*
 toxicity of, 284*t*
- Naratriptan, ventricular arrhythmias caused by, 14*t*
- Narcan. *See* naloxone, **469–472**
- Narcissus/*Narcissus* spp, 312*t*, 315*t*. *See also* plants, **309–319**
- Nardil. *See* phenelzine, 269–271
- Nasal cannula, for oxygen therapy, 483, 483*t*
- Nasal decongestants, **320–322**, 321*t*. *See also* cionidine and related drugs, **169–171**; decongestants, **320–322**
- Nasal spray, nicotine. *See also* nicotine, **277–278**
 toxicity of, 277
- NaSH (sodium bisulfide), hazard summary for, 612*t*
- Nasopharyngeal artificial airway, 4
- Nasotracheal intubation, 5, 5*f*
- Nateglinide. *See also* antidiabetic (hypoglycemic) agents, **93–96**
 pharmacokinetics of, 395*t*
 toxicity of, 94*t*

 pharmacokinetics of, 108
 seizures caused by, 23*t*
 toxicity of, **107–109**, 107*t*
 ventilatory failure caused by, 6*t*
- Neurologic disorders
 arsenic poisoning and, 116
 in hypertension, 18
 in mushroom poisoning, 272*t*
- NeuroMod. *See* 1,4-butanediol, 210–213, 211*t*
- Neuromuscular blocking agents, **472–475**, 473*t*
 glycopyrrolate in reversal of, 412
 for hyperthermia, 22, 472–475
 in agitation/delirium/psychosis, 25
 in seizures, 24
 neostigmine for reversal of, 489–491
 for orotracheal intubation, 5–6, 472–475
 pharmacology/use of, **472–475**, 473*t*
 for tricyclic antidepressant-induced seizures, 92
 ventilatory failure caused by, 6*t*, 474
- Neurontin. *See* gabapentin, 86*t*, 87
- Neuropathy
 arsenic causing, 31*t*, 116
 in diagnosis of poisoning, 30, 31*t*
 lead causing, 31*t*, 239
 occupational causes of, 523
 in organophosphate poisoning, 31*t*, 293
 in Vacor (PNU) poisoning, 361
- Neurotoxic disorders
 antiviral and antiretroviral agents causing, 111
 occupational causes of, 522*t*, 523
- Neurotoxic shellfish poisoning, 205–207, 206*t*
- Nevirapine. *See also* antiviral and antiretroviral agents, **111–115**
 pharmacokinetics of, 395*t*
 toxicity of, 113*t*, 114
- Newborns, 62–63
 drug withdrawal in, 62–63
 pharmacokinetics in, 62
 tetanus in, 351–352
 vital signs in, 61*t*, 62
- Newspaper. *See also* nontoxic products, **286**
 accidental exposure to, 287*t*
- N-Force. *See* 1,4-butanediol, 210–213, 211*t*
- NFPA (National Fire Protection Association)
 exposure guidelines and, 528–530
 labeling system for hazardous chemicals and, 512, 512–513*f*, 529–530
- Niacin. *See also* vitamins, **366–367**
 diphenhydramine for overdose/toxicity of, 436–437
 pharmacokinetics of, 395*t*
 toxicity of, 366–367
- Niacinamide (nicotinamide), **475–476**
 pharmacology/use of, **475–476**
 for Vacor (PNU) poisoning, 362, 475–476
- Niaspan. *See* niacin, 366–367
- Nicardipine. *See also* calcium antagonists, **144–147**
 hypotension caused by, 16*t*
 pharmacokinetics of, 395*t*
 toxicity of, 144, 145*t*
 ventricular arrhythmias caused by, 14*t*
- Nickel (metal), hazard summary for, 596*t*
- Nickel carbonyl (nickel tetracarbonyl), hazard summary for, 595*t*
- Nickel salts (nickle chloride/nitrate/oxide/sulfate), hazard summary for, 596*t*
- Nicoderm. *See* nicotine, **277–278**
- Nicorette gum. *See* nicotine, **277–278**
- Nicotiana* spp, 317*t*. *See also* nicotine, **277–278**; plants, **309–319**

- Nicotinamide (niacinamide), **475–476**
pharmacology/use of, **475–476**
for Vacor (PNU) poisoning, 362, 475–476
- Nicotine, **277–278**. *See also* plants, **309–319**
hazard summary for, 596t
hypertension caused by, 18t, 278
miosis caused by, 30t, 278
mydriasis caused by, 30t, 278
pharmacokinetics of, 277, 395t
seizures caused by, 23t, 278
toxicity of, **277–278**, 310t
ventilatory failure caused by, 6t, 278
- Nicotine chewing gum. *See also* nicotine, **277–278**
toxicity of, 277
- Nicotine inhaler systems. *See also* nicotine, **277–278**
toxicity of, 277
- Nicotine lozenges. *See also* nicotine, **277–278**
toxicity of, 277
- Nicotine nasal spray. *See also* nicotine, **277–278**
toxicity of, 277
- Nicotine patches, transdermal. *See also* nicotine, **277–278**
toxicity of, 277
- Nicotinic cholinergic syndrome, 29, 29t
- Nicotrol. *See* nicotine, **277–278**
- Nifedipine. *See also* calcium antagonists, **144–147**
hypotension caused by, 16t
pharmacokinetics of, 396t
toxicity of, 144, 145t
- Night jessamine, 314t. *See also* plants, **309–319**
- Nightshade, 315t. *See also* plants, **309–319**
black, 311t, 315t
deadly, 313t, 315t
- Nilutamide. *See also* antineoplastic agents, **100–107**
toxicity of, 103t
- Nimbex. *See* cisatracurium, 473t, 475
- Nimodipine. *See also* calcium antagonists, **144–147**
toxicity of, 144
- Nipent. *See* pentostatin, 102t
- Nipride. *See* nitroprusside, **281–282**, **477–479**
- Nisoldipine. *See also* calcium antagonists, **144–147**
pharmacokinetics of, 396t
toxicity of, 145t
- Nitramine (tetryl), hazard summary for, 619t
- Nitrate oxidants, job processes associated with exposure to, 521t
- Nitrates, **279–280**
narrow anion gap caused by, 33
toxicity of, **279–280**
withdrawal from, coronary artery spasms caused by, 523
- Nitrendipine. *See also* calcium antagonists, **144–147**
pharmacokinetics of, 396t
toxicity of, 144, 155t
- Nitric acid. *See also* gases, irritant, **213–215**
exposure limits for, 214t, 596t
hazard summary for, 596t
toxicity of, 214t
- Nitric acid n-propyl ester (*n*-propyl nitrate), hazard summary for, 608t
- Nitric oxide. *See also* gases, irritant, **213–215**
exposure limits for, 214t, 280, 596t
hazard summary for, 596t
toxicity of, 214t, 280–281
- Nitrites, **279–280**, **476–477**, 477t
for cyanide poisoning, 178, 377, 476–477
for hydrogen sulfide poisoning, 224, 476–477
hypotension caused by, 16t, 279
pharmacology/use of, **476–477**, 477t
toxicity of, **279–280**, 476
- p*-Nitroaniline, hazard summary for, 597t
- Nitrobenzene, hazard summary for, 597t
- 4-Nitrobiphenyl (4-nitrodiphenyl), hazard summary for, 597t
- p*-Nitrochlorobenzene, hazard summary for, 597t
- 4-Nitrodiphenyl, hazard summary for, 597t
- Nitro Dur. *See* nitroglycerin, 279–280
- Nitroethane
hazard summary for, 597t
job processes associated with exposure to, 521t
- Nitrofurantoin. *See also* antibacterial agents, **81–84**
neuropathy caused by, 31t
- pharmacokinetics of, 396t
toxicity of, 83t
- Nitrogen, hypoxia caused by, 7t
- Nitrogen-based fertilizers. *See also* low-toxicity products, **286**
accidental exposure to, 287t
- Nitrogen dioxide. *See also* gases, irritant, **213–215**
exposure limits for, 214t, 280, 597t
hazard summary for, 597t
hypoxia caused by, 7t
job processes associated with exposure to, 521t
toxicity of, 214, 214t, 280–281
- Nitrogen fluoride (nitrogen trifluoride), hazard summary for, 598t
- Nitrogen monoxide (nitric oxide). *See also* gases, irritant, **213–215**
exposure limits for, 214t, 280, 596t
hazard summary for, 596t
toxicity of, 214t, 280–281
- Nitrogen mustard, as chemical weapon, 372. *See also* warfare agents, chemical, **372–378**
- Nitrogen oxides, **280–281**
exposure limits for, 280
toxicity of, **280–281**
- Nitrogen trifluoride, hazard summary for, 598t
- Nitroglycerin
contraindications to sildenafil use and, 279
for ergot overdose, 190
hazard summary for, 598t
toxicity of, 279–280
- Nitromethane, hazard summary for, 598t
- O*-ethyl *O*-*p*-Nitrophenyl phenylphosphonothioate (EPN). *See also* organophosphates and carbamates, **291–295**
hazard summary for, 568t
toxicity of, 292t
- Nitropress. *See* nitroprusside, **281–282**, **477–479**
- 1-Nitropropane, hazard summary for, 598t
- 2-Nitropropane
hazard summary for, 598t
hepatic failure caused by, 40t
- Nitroprusside, **281–282**, **477–479**
cyanide released from, 177, 178, 281–282, 478
hydroxocobalamin prophylaxis/treatment and, 282, 453–454, 478
thiosulfate prophylaxis/treatment and, 282, 478, 505–506
for ergot overdose, 190, 477–479
for hypertension, 18, 281, 322, 477–479
hypotension caused by, 16t, 282
pharmacokinetics of, 396t
pharmacology/use of, **477–479**
thiocyanate intoxication caused by, 281–282, 478
toxicity of, **281–282**, 478
- Nitrosamine, hepatic failure caused by, 40t
- N*-Nitrosodimethylamine, hazard summary for, 598t
- Nitrostat. *See* nitroglycerin, 279–280
- Nitrotoluene (*o*-, *m*-, *p*-nitrotoluene), hazard summary for, 599t
- Nitrous oxide, **282–283**
exposure limits for, 283, 599t
hazard summary for, 599t
neuropathy caused by, 31t, 283
toxicity of, **282–283**
- Nix Creme Rinse. *See* permethrin, 323t
- Nizatidine. *See also* H₂ blockers, **428–430**
pharmacology/use of, 428–430, 430t
- NMS (neuroleptic malignant syndrome), 21t, 22, 108
bromocriptine for, 22, 422–424
rigidity in, 22, 26, 26t
- N,N*-dimethyltryptamine (DMT), 248t. *See also* hallucinogens, **247–249**
toxicity of, 248t
- NNRTI (non-nucleoside reverse transcriptase inhibitors). *See also* antiviral and antiretroviral agents, **111–115**
toxicity of, 113t
- NO (nitric oxide). *See also* gases, irritant, **213–215**
exposure limits for, 214t, 280, 596t
hazard summary for, 596t
toxicity of, 214t, 280–281

- NoDoz. *See* caffeine, **142–144**

carcinogen regulation and, 529
exposure limits set by, 529
regional offices of, 525*t*
- Osmium tetroxide (osmic acid), hazard summary for, 599*t*
- Osmolality
serum, in diagnosis of poisoning, 32–33, 32*t*, 33*t*
in toxicology screens, interferences and, 44*t*
- Osmolar (osmolal) gap
alcohol and glycol levels estimated from, 33*t*
with anion gap acidosis, 32, 33
in diagnosis of poisoning, 32–33, 32*t*, 33*t*
elevation of
causes of, 32–33, 32*t*
treatment of, 33
- Osmotic contrast dyes, osmolar gap elevation caused by, 32*t*
- Osmotic diuresis, for arsine gas poisoning, 120
- Ototoxicity, occupational, 523
- “Ouch-ouch” disease, cadmium causing, 142
- Overdrive pacing, for atypical/polymorphic ventricular tachycardia (torsade de pointes), 15
in beta-adrenergic blocker overdose, 133
in tricyclic antidepressant overdose, 92
- Oxalic acid/oxalates, **295–296**. *See also* caustic and corrosive agents, **157–159**
calcium for poisoning caused by, 296, 424–426
exposure limits for, 295, 599*t*
hazard summary for, 599*t*
renal failure caused by, 39*t*
topical treatment for exposure to, 47*t*
toxicity of, 158*t*, **295–296**
- Oxalis* spp, 317*t*. *See also* plants, **309–319**
- Oxalonnitrile (cyanogen), hazard summary for, 555*t*
- Oxamyl. *See also* organophosphates and carbamates, **291–295**
toxicity of, 293*t*
- Oxaprozin. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
pharmacokinetics of, 396*t*
toxicity of, 284*t*
- Oxazepam. *See also* benzodiazepines, **129–131**, **415–418**
pharmacokinetics of, 396*t*
toxicity of, 130*t*
- Oxcarbazine, pharmacokinetics of, 396*t*
- Oxidizing agents
caustic/corrosive injury caused by, 157–159
renal failure caused by, 39*t*
tachycardia caused by, 13*t*
- Oximes, **492–494**
for cholinesterase inhibitor insecticide and nerve agent exposures, 294–295, 377, 492–494
pharmacology/use of, **492–494**
- Oxybutynin. *See also* anticholinergic agents, **84–86**
pharmacokinetics of, 396*t*
toxicity of, 85*t*
- Oxycodone, 289*t*. *See also* opiates/opioids, **286–291**
pharmacokinetics of, 396*t*
toxicity of, 289*t*
in toxicology screens, 41*t*

- OxyContin. *See* oxycodone, 289t
- Oxymeteton-methyl. *See also* organophosphates and carbamates, **291–295**
toxicity of, 292t
- Oxydeprofos. *See also* organophosphates and carbamates, **291–295**
toxicity of, 292t
- OxyFAST. *See* oxycodone, 289t
- Oxygen
insufficient, in hypoxia, 7
pharmacology/use of, **482–484**, 483t
triatomic (ozone). *See also* gases, irritant, **213–215**
exposure limits for, 214t, 600t
hazard summary for, 600t
job processes associated with exposure to, 521t

- Potassium cyanide. *See also* cyanide, **177–179**
hazard summary for, 555t
- Potassium dichromate, toxicity of, 167
- Potassium hydroxide, hazard summary for, 606t
- Potassium iodide (KI), **456–457**. *See also* iodine, **226–228**
pharmacology/use of, **456–457**
for radiation poisoning, 330t, 456–457
toxicity of, 226
- Potassium nitrate/nitrite, toxicity of, 279–280
- Potassium permanganate. *See also* antiseptics/disinfectants, **109–111**; caustic and corrosive agents, **157–159**
toxicity of, 109, 110, 158t
- Potassium-sparing diuretics. *See also* diuretics, **187–189**
toxicity of, 188t
- Potato (unripe/leaves), 316t. *See also* plants, **309–319**
- Pothos, 316t. *See also* plants, **309–319**
- Potomania, beer, 36t, 37

- Pottery glazing, toxic exposures and, 521*t*
 Povidone-iodine. *See also* iodine, **226–228**
 toxicity of, 226
 PPA. *See* phenylpropanolamine, **320–322**
 p-phenylaniline (4-aminodiphenyl), hazard summary for, 536*t*
 Pralidoxime (2-PAM), **492–494**
 for cholinesterase inhibitor insecticide and nerve agent exposures, 294–295, 492–494
 for organophosphate poisoning, 294–295, 492–494
 pharmacology/use of, **492–494**
 Pramoxine. *See also* anesthetics, local, **74–77**
 toxicity of, 75*t*
 Pramoxine. *See* pramoxine, 75*t*
 Prairie crocus, 312*t*. *See also* plants, **309–319**
 Prax Lotion. *See* pramoxine, 75*t*
 Prayer bean, 316*t*. *See also* plants, **309–319**
 Prazosin
 hypotension caused by, 16*t*
 pharmacokinetics of, 398*t*
 toxicity of, 365–366
 Precose. *See* acarbose, 94*t*
 Prednisone
 accidental ingestion of, 287*t*. *See also* low-toxicity products, **286**
 agitation caused by, 24*t*
 psychosis caused by, 24*t*
 Pregnancy
 antidote use in, 404, 405*t*
 black widow envenomation during, 409
 Listeria food contamination and, 205
 overdose in, 58–59
 acetaminophen, 66
 radiation exposure during, 328
 unwanted, overdose and, 58–59
 Prelu-2. *See* phendimetrazine, 72, 73*t*
 Prickly pear (thorn), 316*t*. *See also* plants, **309–319**
 Prickly poppy, 316*t*. *See also* plants, **309–319**
 Pride of China, 316*t*. *See also* plants, **309–319**
 Pride of India, 316*t*. *See also* plants, **309–319**
 Pride-of-Madeira, 316*t*. *See also* plants, **309–319**
 Priilocaine. *See also* anesthetics, local, **74–77**
 toxicity of, 75, 75*t*, 76
 Primaquine
 pharmacokinetics of, 166, 398*t*
 toxicity of, 165–167
 Primidone. *See also* barbiturates, **124–126**
 pharmacokinetics of, 124–125, 398*t*
 in toxicology screens, 41*t*
 Primiphos-ethyl. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
 Primiphos-methyl. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
 Primrose, 316*t*. *See also* plants, **309–319**
 Primula vulgaris, 316*t*. *See also* plants, **309–319**
 Prinivil. *See* lisinopril, 77
 Privet, 316*t*. *See also* plants, **309–319**
 California, 312*t*
 common, 316*t*
 Pro-Banthine. *See* propantheline, 85*t*
 Procainamide, **324–326**, 324*t*
 atrioventricular (AV) block caused by, 10*t*
 bradycardia caused by, 10*t*, 325
 elimination of, 56*t*
 hypotension caused by, 16*t*
 hypoxia caused by, 7*t*
 pharmacokinetics of, 398*t*
 QRS interval prolongation caused by, 11*t*, 325
 toxicity of, **324–326**, 324*t*
 in toxicology screens, 41*t*
 ventricular arrhythmias caused by, 14*t*, 325
 volume of distribution of, 56*t*, 398*t*
 Procaine. *See also* anesthetics, local, **74–77**
 agitation caused by, 24*t*
 psychosis caused by, 24*t*
 toxicity of, 75*t*
 Procanbid. *See* procainamide, **324–326**
 Procarbazine. *See also* antineoplastic agents, **100–107**;
 monoamine oxidase inhibitors, **269–271**
 pharmacokinetics of, 398*t*
 toxicity of, 105*t*, 269–271
 Procardia. *See* nifedipine, 144, 145*t*
 Prochlorperazine. *See also* antipsychotic drugs, **107–109**
 abdominal x-ray showing, 46*t*
 dystonia caused by, 26*t*
 pharmacokinetics of, 398*t*
 toxicity of, 107*t*
 in toxicology screens, 41*t*
 Procyanidins, 217*t*. *See also* herbal and alternative products, **215–218**
 Procyclidine. *See also* anticholinergic agents, **84–86**
 pharmacokinetics of, 398*t*
 toxicity of, 85*t*
 Product labels
 for information about substance involved in hazardous materials incident, 512, 512–513*t*, 529–530
 for information about substance involved in occupational exposure, 520
 Profenofos. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
 ProG. *See* 1,4-butanediol, 210–213, 211*t*
 Progestins, as antineoplastic agents. *See also* antineoplastic agents, **100–107**
 toxicity of, 103*t*
 Proglycem. *See* diazoxide, **433–434**
 Proleukin. *See* aldesleukin, 104*t*
 Prolonged insulin zinc. *See also* insulin, 93–96, **455–456**
 pharmacokinetics of, 391*t*
 toxicity of, 94*t*
 Promecarb. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 293*t*
 Promethazine. *See also* antihistamines, **96–98**; antipsychotic drugs, **107–109**
 pharmacokinetics of, 398*t*
 toxicity of, 97*t*, 107*t*
 Promusol. *See* 1,4-butanediol, 210–213, 211*t*
 Pronestyl. *See* procainamide, **324–326**
 Propacet. *See*
 acetaminophen, **66–69**
 propoxyphene, 289, 289*t*
 Propafenone. *See also* antiarrhythmic drugs, **78–81**
 pharmacokinetics of, 398*t*
 toxicity of, 79*t*, 80
 Propane
 1,2-epoxy-3-butoxy (*n*-butyl glycidyl ether), hazard summary for, 544*t*
 hazard summary for, 606*t*
 hypoxia caused by, 7*t*
 1-Propanol (propyl alcohol), hazard summary for, 607*t*
 2-Propanol (isopropyl alcohol), **234–236**
 for chemical exposures to skin, 47*t*
 elimination of, 56*t*
 estimation of level of from osmolar gap, 33*t*, 235
 exposure limits for, 235, 582*t*
 hazard summary for, 582*t*
 odor caused by, 32*t*, 235
 osmolar gap elevation caused by, 32*t*, 235
 pharmacokinetics of, 235
 toxicity of, **234–236**
 in toxicology screens, 41*t*
 interferences and, 44*t*
 volume of distribution of, 56*t*, 235
 2,3-epoxy-1-Propanol (glycidol), hazard summary for, 576*t*
 2-Propanone (acetone)
 drugs or toxins causing odor of, 32*t*
 estimation of level of from osmolar gap, 33*t*
 hazard summary for, 533*t*
 osmolar gap elevation caused by, 32*t*
 in toxicology screens, 41*t*
 Propantheline. *See also* anticholinergic agents, **84–86**
 pharmacokinetics of, 398*t*
 toxicity of, 85*t*
 Proparacaine. *See also* anesthetics, local, **74–77**
 toxicity of, 75*t*

- Propargyl alcohol, hazard summary for, 607t
- 2-Propenal (acrolein). *See also* gases, irritant, **213–215**
 exposure limits for, 214t, 534t
 hazard summary for, 534t
 job processes associated with exposure to, 521t
 toxicity of, 214t
- Propenamide (acrylamide)
 hazard summary for, 534t
 neuropathy caused by, 31t
- Propenenitrile (acrylonitrile). *See also* cyanide, **177–179**
 acetylcysteine for poisoning caused by, 405–407
 hazard summary for, 534t
 toxicity of, 177
- Propenoic acid (acrylic acid), hazard summary for, 534t
- 2-Propenoic acid methyl ester (methyl acrylate), hazard summary for, 588t
- 2-Propen-1-ol (allyl alcohol), hazard summary for, 535t
- Propetamphos. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292t
- Propionic acid
 anion gap acidosis caused by, 34t
 hazard summary for, 607t
- Propionitrile. *See also* cyanide, **177–179**
 toxicity of, 177
- Propofol, **494–496**
 pharmacology/use of, **494–496**
 for seizures, 24, 494–496
- Propoxur. *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 607t
 toxicity of, 293t
- Propoxycaïne. *See also* anesthetics, local, **74–77**
 toxicity of, 75t
- Propoxyphene, 289t. *See also* opiates/opioids, **286–291**
 atrioventricular (AV) block caused by, 10t
 bradycardia caused by, 10t
 cardiotoxicity of, 289
 hypotension caused by, 16t
 pharmacokinetics of, 398t
 QRS interval prolongation caused by, 11t
 toxicity of, 289, 289t
 in toxicology screens, 41t
- Propranolol, 132t, **496–497**. *See also* beta-adrenergic blockers, **131–133**
 atrioventricular (AV) block caused by, 10t, 496
 for beta-agonist overdose, 135, 496–497
 bradycardia caused by, 10t, 496
 for caffeine poisoning, 144, 496–497
 for carbon tetrachloride poisoning, 155
 for chloroform poisoning, 155
 for cocaine overdose, 173, 496–497
 for freon toxicity, 210
 for hypertension, 18, 496–497
 hypoglycemia caused by, 35t
 hypotension caused by, 16t, 497
 for methylene chloride poisoning, 266
 pharmacokinetics of, 399t
 pharmacology/use of, **496–497**
 QRS interval prolongation caused by, 11t
 for sedative-hypnotic overdose, 336
 seizures caused by, 23t
 for tachycardia, 13, 15, 496–497
 for theophylline overdose, 355, 496–497
 for thyroid hormone overdose, 357
 for toluene and xylene poisoning, 358
 toxicity of, 131, 132t, 496–497
 in toxicology screens, 41t
 for trichloroethane/trichloroethylene/perchloroethylene poisoning, 360
- n*-Propyl acetate, hazard summary for, 607t
- Propyl alcohol, hazard summary for, 607t
- Propylene dichloride, hazard summary for, 607t
- Propylene glycol. *See also* glycols, **194–198**
 estimation of level of from osmolar gap, 33t
 osmolar gap elevation caused by, 32t
 in phenytoin preparation, toxicity of, 303, 304, 489
 toxicity of, 195t, 197
- Propylene glycol dinitrate (1,2-propylene glycol dinitrate), hazard summary for, 608t
- Propylene glycol monomethyl ether, hazard summary for, 608t
- Propylene imine, hazard summary for, 608t
- Propylene oxide, hazard summary for, 608t
- n*-Propyl nitrate, hazard summary for, 608t
- Propylthiopyrophosphate. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292t
- Propylthiouracil, for thyroid hormone overdose, 357
- Propyne (methyl acetylene), hazard summary for, 587t
- 2-Propyn-1-ol (propargyl alcohol), hazard summary for, 607t
- ProSom. *See* estazolam, 130t
- Prostep. *See* nicotine, **277–278**
- Prostigmin. *See* neostigmine, **489–491**
- Protamine, pharmacology/use of, **497–498**
- Protamine zinc insulin. *See also* insulin, 93–96, **455–456**
 pharmacokinetics of, 391t
 toxicity of, 94t
- Protease inhibitors, 111. *See also* antiviral and antiretroviral agents, **111–115**
 toxicity of, 113t
- Protective equipment, personal
 information about in occupational-exposure history, 519
 for response in hazardous materials incident, 515
- Protein binding, accessibility to removal by enhanced elimination and, 54
- Prothoate. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292t
- Prothrombin time (PT), in anticoagulant-based rodenticide poisoning, 379
- Protoanemonin. *See also* plants, **309–319**
 toxicity of, 310t
- Protopam. *See* pralidoxime (2-PAM), **492–494**
- Protoporphyrin levels, in lead poisoning, 240
- Protriptyline. *See also* tricyclic antidepressants, **90–93**
 pharmacokinetics of, 399t
 toxicity of, 88t
 in toxicology screens, 41t
- Proventil. *See* albuterol, 134t
- Provera. *See* medroxyprogesterone, 103t
- Prozac. *See* fluoxetine, 88, 88t, 89
- Prunus* spp, 311t, 312t, 315t. *See also* cyanide, **177–179**;
 plants, **309–319**
- Prunus laurocerasus*, 313t. *See also* plants, **309–319**
- Prunus virginiana*, 312t. *See also* plants, **309–319**
- Pruritus, diphenhydramine for, 436–437
- Prussian blue (ferric hexacyanoferrate), **499**
 as binding agent, 53t, 330t
 pharmacology/use of, **499**
 for radiation poisoning, 330t, 499
 for thallium poisoning, 353, 499
- Prussic acid. *See also* hydrogen cyanide gas, **177–179**
 hazard summary for, 579t
- Pseudoephedrine, **320–322**, 321t
 hypertension caused by, 18t, 321
 pharmacokinetics of, 320, 399t
 propranolol for overdose of, 322, 496–497
 tachycardia caused by, 13t
 toxicity of, **320–322**
- Pseudohyponatremia, 36
- Pseudotumor cerebri, vitamin A-induced, mannitol for, 464–465
- Psilocybe cubensis* mushrooms. *See also* mushroom poisoning, **271–275**
 toxicity of, 272t
- Psilocybin (4-phosphoryloxy-*N,N*-dimethyltryptamine), 248t.
See also hallucinogens, **247–249**
 toxicity of, 248t, 272t
- Psilocyn, toxicity of, 272t
- Psychiatric consultation, for suicide risk, 58
- Psychogenic polydipsia, 36t, 37
- Psychological disorders, work-related, 522t, 523–524
- Psychosis, **24–25**, 24t
 drugs and toxins causing, 24t
 treatment of, 25
 haloperidol/droperidol for, 25, 451–453

- Psychosocial evaluation, 58
 PT (prothrombin time), in anticoagulant-based rodenticide poisoning, 379
Pteridium aquilinum, 311*t*. *See also* plants, **309–319**
 Pterois envenomation, 243–244
 Puff adder envenomation, 343*t*. *See also* snakebites, **343–346**

 anion gap/lactic acidosis associated with, 34*t*
 drugs and toxins causing, 23*t*
 rhabdomyolysis associated with, 27*t*
 treatment of, 23–24
 benzodiazepines for, 24, 415–418
 fosphenytoin for, 488–489
 glucose for, 450–451
 pentobarbital for, 24, 485–486
 phenobarbital for, 24, 486–487
 phenytoin for, 24, 303, 488–489
 primidone for, 124–125
 propofol for, 24, 494–496
 valproic acid for, 362
- Seldane. *See* terfenadine, 97*t*, 98
- Selegiline. *See also* monoamine oxidase inhibitors, **269–271**
 amphetamine blood test interference and, 74
 pharmacokinetics of, 400*t*
 toxicity of, 269–271
- Selenic acid. *See also* selenium, **337–339**
 toxicity of, 338*t*
- Selenious acid (gun bluing). *See also* selenium, **337–339**
 toxicity of, 337–338, 338*t*
 in children, 60*t*
- Selenium/elemental selenium, **337–339**, 338*t*
 exposure limits for, 337, 610*t*
 hazard summary for, 610*t*
 neuropathy caused by, 31*t*
 odor caused by, 32*t*, 337, 338
 toxicity of, **337–339**, 338*t*
- Selenium dioxide (selenium oxide). *See also* selenium, **337–339**
 hazard summary for, 610*t*
 toxicity of, 338, 338*t*
- Selenium hexafluoride (selenium fluoride). *See also* selenium, **337–339**
 hazard summary for, 611*t*
 toxicity of, 338, 338*t*
- Selenium hydride (hydrogen selenide). *See also* selenium, **337–339**
 hazard summary for, 579*t*
 toxicity of, 338, 338*t*
- Selenium oxide (selenium dioxide). *See also* selenium, **337–339**
 hazard summary for, 610*t*
 toxicity of, 338, 338*t*
- Selenium oxychloride, hazard summary for, 611*t*
- Selenium salt. *See also* selenium, **337–339**
 toxicity of, 338
- Selenium trioxide (sodium selenite). *See also* selenium, **337–339**
 toxicity of, 338, 338*t*
- Self-contained breathing apparatus, for personal protection during response in hazardous materials incidents, 515
- Semilente insulin (rapid insulin zinc). *See also* insulin, 93–96, **455–456**
 pharmacokinetics of, 391*t*
 toxicity of, 94*t*
- Semprex-D. *See* acrivastine, 97*t*
- Pseudoephedrine, **320–322**

 teratogenic effects of, 59*t*
 toxicity of, **186–187**
 warfarin interaction and, 379*t*
- 1,2,3,4-Tetrahydrobenzene (cyclohexene), hazard summary for, 556*t*
- Δ-9-Tetrahydrocannabinol (THC), 252. *See also* marijuana, **252–254**
 in “drugs of abuse” panel, 42*t*
 toxicity of, 252, 253
- Tetrahydrofuran, hazard summary for, 618*t*
- Tetrahydro-1,4-oxazine (morpholine), hazard summary for, 595*t*
- Tetrahydropalmatine, 216*t*. *See also* herbal and alternative products, **215–218**
- Tetrahydrozoline, 169–171
 coma caused by, 19*t*
 hypertension caused by, 18*t*
 hypotension caused by, 16*t*
 miosis caused by, 30*t*
 pharmacokinetics of, 401*t*
 stupor caused by, 19*t*
 toxicity of, 169–171
- Tetraiodothyronine (thyroxine/levothyroxine). *See also* thyroid hormone, **356–357**
 pharmacokinetics of, 392*t*
 toxicity of, 356–357, 356*t*
- Tetramethrin. *See also* pyrethrins/pyrethroids, **322–324**
 toxicity of, 323*t*
- Tetramethyl lead, hazard summary for, 618*t*
- Tetramethyl succinonitrile, hazard summary for, 618*t*
- O,O,O',O'*-Tetramethyl *O,O*-thiodi-*p*-phenylene phosphorothioate (temephos). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 616*t*
 toxicity of, 292*t*
- Tetramethylthiuram disulfide (thiram), hazard summary for, 619*t*
- Tetranitromethane, hazard summary for, 619*t*
- Tetrasodium pyrophosphate, hazard summary for, 619*t*
- Tetrodotoxin, food poisoning caused by, 205–207, 206*t*
- Tetryl, hazard summary for, 619*t*
- Texas umbrella tree, 317*t*. *See also* plants, **309–319**
- Thalidomide, teratogenic effects of, 59*t*
- Thallium, **352–354**
 binding agent for, 53*t*, 353
 hazard summary for, 619*t*
 hepatic failure caused by, 40*t*
 neuropathy caused by, 31*t*
 odor caused by, 32*t*
 Prussian blue (ferric hexocyanoferrate) for poisoning caused by, 353, 499
 toxicity of, **352–354**
 ventricular arrhythmias caused by, 14*t*
- Thallium acetate, hazard summary for, 619*t*
- Thallium nitrate, hazard summary for, 619*t*
- Thallium sulfate, hazard summary for, 619*t*
- Thalomid. *See* thalidomide, 59*t*
- THC (Δ-9-tetrahydrocannabinol), 252. *See also* marijuana, **252–254**
 in “drugs of abuse” panel, 42*t*
 toxicity of, 252, 253
- Thenylidamine. *See also* antihistamines, **96–98**
 toxicity of, 97*t*
- Theo-24. *See* theophylline, **354–356**
- Theobid. *See* theophylline, **354–356**
- Theo-Dur. *See* theophylline, **354–356**
- Theolair. *See* theophylline, **354–356**
- Theophylline, **354–356**
 agitation caused by, 24*t*
 anion gap/lactic acidosis caused by, 34*t*, 354
 elimination of, 56*t*, 354
 esmolol for overdose of, 355, 443–444
 hyperglycemia caused by, 35*t*, 354
 hypokalemia caused by, 38, 38*t*, 354, 355
 hypotension caused by, 16*t*, 354, 355
 metoclopramide for vomiting caused by, 467–468
 pharmacokinetics of, 354, 401*t*
 propranolol for overdose of, 355, 496–497
 psychosis caused by, 24*t*
 quantitative levels/potential interventions and, 45*t*, 355
 repeat-dose activated charcoal for overdose of, 58*t*, 356
 seizures caused by, 23*t*, 354, 355
 tachycardia caused by, 13*t*, 354, 355
 toxicity of, **354–356**
 in children, 60*t*
 in toxicology screens, interferences and, 44*t*
 ventricular arrhythmias caused by, 14*t*, 354, 355
 volume of distribution of, 55*t*, 56*t*, 354, 355
- Theo-X. *See* theophylline, **354–356**
- Thermal-breakdown products, 531
- Thermal injury, smoke inhalation and, 341, 342
- “Thermogenic” dietary supplements, toxicity of, caffeine and, 143
- Thermometers. *See also* nontoxic products, **286**
 accidental exposure to, 287*t*, 288*t*
- Thevetia peruviana*, 311*t*, 315*t*, 318*t*. *See also* plants, **309–319**
- THF (tetrahydrofuran), hazard summary for, 618*t*
- Thiamine (vitamin B₁), **505**
 abdominal x-ray showing, 46*t*
 for alcohol-related disorders, 192
 for coma and stupor, 20, 505
 for ethylene glycol poisoning, 198, 505
 for hypoglycemia, 35
 pharmacology/use of, **505**
- Thiazide diuretics. *See also* diuretics, **187–189**
 hyperglycemia caused by, 35*t*
 toxicity of, 188*t*
- Thiazolidinediones (glitazones). *See also* antidiabetic (hypoglycemic) agents, **93–96**
 pharmacokinetics of, 94*t*
 toxicity of, 93, 94*t*
- Thimet (phorate). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 603*t*
 toxicity of, 292*t*
- Thiocyanate toxicity
 elimination and, 56*t*
 from nitroprusside infusion, 281–282, 478
- Thiodicarb. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 293*t*
- Thioglycolic acid, hazard summary for, 619*t*
- 6-Thioguanine. *See also* antineoplastic agents, **100–107**
 toxicity of, 102*t*
- Thiometon. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*

- Thiopental. *See also* barbiturates, **124–126**
 pharmacokinetics of, 125*t*, 401*t*
 toxicity of, 125*t*
- Thioplex. *See* thiotepa, 101*t*
- Thioridazine. *See also* antipsychotic drugs, **107–109**
 pharmacokinetics of, 401*t*
 QRS interval prolongation caused by, 11*t*
 toxicity of, 107*t*
 in children, 60*t*
 ventricular arrhythmias caused by, 14*t*
- Thiosulfate, sodium, **505–506**
 for antineoplastic infusion extravasation, 106, 505–506
 for bromate poisoning, 139, 505–506
 for chlorate poisoning, 160
 for cyanide poisoning, 178, 377, 505–506
 nitroprusside-induced, 478, 505–506
 in smoke inhalation, 342, 505–506
 for iodine poisoning, 227
 pharmacology/use of, **505–506**
- Thiotepa. *See also* antineoplastic agents, **100–107**
 toxicity of, 101*t*
- Thiothixene. *See also* antipsychotic drugs, **107–109**
 pharmacokinetics of, 401*t*
 toxicity of, 107*t*
- Thiram, hazard summary for, 619*t*
- Third spacing, hypotension caused by, 16*t*
- Thisilyn. *See* milk thistle, **500–501**
- Thompson's Water Seal. *See* aliphatic hydrocarbons, 219
- Thorazine. *See* chlorpromazine, 107*t*
- Thornapple, 317*t*. *See also* plants, **309–319**
- Threshold Limit Value (TLV), 528–529
- Threshold Limit Value Ceiling (TLV-C), 528
- Threshold Limit Value Time-Weighted Average (TLV-TWA), 528
- Thrombocytopenia, antineoplastic agents causing, 100
- Thuja* spp., 312*t*. *See also* plants, **309–319**
- Thunder. *See* 1,4-butanediol/gamma-butyrolactone, 210–213, 211*t*
- Thunder Nectar. *See* 1,4-butanediol, 210–213, 211*t*
- Thymol. *See also* essential oils, **147–148**
 toxicity of, 147*t*
- Thyro-Block. *See* potassium iodide, **456–457**
- Thyroid hormone, **356–357**, 356*t*
 desiccated
 pharmacokinetics of, 401*t*
 toxicity of, 356–357, 356*t*
 hyperthermia caused by, 21*t*, 356
 tachycardia caused by, 13*t*, 356, 357
 toxicity of, **356–357**, 356*t*
- Thyrolar. *See* triiodothyronine, 356–357
- Thyroxine (levothyroxine). *See also* thyroid hormone, **354–356**
 pharmacokinetics of, 392*t*
 toxicity of, 356–357, 356*t*
- Tiagabine. *See also* anticonvulsants, **86–87**
 pharmacokinetics of, 401*t*
 toxicity of, 86*t*, 87
- Tiazac. *See* diltiazem, 144, 145*t*
- Ticar. *See* ticarcillin, 83*t*
- Ticarcillin. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 401*t*
 toxicity of, 83*t*
- Tick paralysis, neuropathy associated with, 31*t*
- Tidal volume, for mechanical ventilation, 7
- TIG (human tetanus immune globulin), 352, **503–505**
 pharmacology/use of, **503–505**
- Tigan. *See* trimethobenzamide/trimethobenzamine, 107*t*
- Tilex Instant Mildew Stain Remover. *See*
 caustic and corrosive agents, **157–159**
 hypochlorite, 162–164
 sodium hydroxide, 313
- Timet (phorate). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 603*t*
 toxicity of, 292*t*
- Timolide. *See*
 hydrochlorothiazide, 188*t*
 timolol, 132*t*
- Timolol. *See also* beta-adrenergic blockers, **131–133**
 pharmacokinetics of, 401*t*
 toxicity of, 132*t*
- Timoptic. *See* timolol, 132*t*
- Tin
 metal and inorganic compounds of, hazard summary for, 620*t*
 organic compounds of, hazard summary for, 620*t*
- Tinazaparin, protamine for overdose of, 497–498
- Tincture of iodine. *See* iodine, **226–228**
- Titanium dioxide, hazard summary for, 620*t*
- Tityus* spp scorpion envenomation, 334–335
- Tizanidine. *See also* clonidine, **169–171**
 pharmacokinetics of, 401*t*
 toxicity of, 169–171, 340
 ventricular arrhythmias caused by, 14*t*
- TLV (Threshold Limit Value), 528–529
- TLV-C (Threshold Limit Value Ceiling), 528
- TLV-TWA (Threshold Limit Value Time-Weighted Average), 528
- TMAN (trimellitic anhydride)
 hazard summary for, 623*t*
 job processes associated with exposure to, 521*t*
- TMB4, 492, 493. *See also* oximes, **492–494**
- TMSN (tetramethyl succinonitrile), hazard summary for, 618*t*
- TNT (trinitrotoluene), hazard summary for, 624*t*
- Toad venom, cardiac glycosides in, 155, 216*t*. *See also* cardiac (digitalis) glycosides, **155–157**; herbal and alternative products, **215–218**
- Tobacco. *See also* nicotine, **277–278**; plants, **309–319**
 environmental smoke from, hazard summary for, 568*t*
 Indian, 317*t*
 toxicity of, 277–278, 317*t*
- Tobramycin. *See also* antibacterial agents, **81–84**
 pharmacokinetics of, 401*t*
 toxicity of, 82*t*
- Tocainide. *See also* antiarrhythmic drugs, **78–81**
 pharmacokinetics of, 79, 401*t*
 toxicity of, 79–80, 79*t*
- TOCP (triorthocresyl phosphate). *See also* organophosphates and carbamates, **291–295**
 hazard summary for, 624*t*
 toxicity of, 292*t*
- Toddlers. *See also* children, poisoning in, **59–60**
 poisoning in, 59–60, 60*t*
- Tofranil. *See* imipramine, 88*t*
- Tolazamide. *See also* antidiabetic (hypoglycemic) agents, **93–96**
 pharmacokinetics of, 401*t*
 toxicity of, 94*t*
- Tolazoline
 contraindications to for clonidine overdose, 170
 pharmacokinetics of, 401*t*
 toxicity of, 365–366
- Tolbutamide. *See also* antidiabetic (hypoglycemic) agents, **93–96**
 pharmacokinetics of, 401*t*
 toxicity of, 94*t*
- Tolectin. *See* tolmetin, 284*t*
- Tolidine (*o*-tolidine), hazard summary for, 620*t*
- Tolmetin. *See also* nonsteroidal anti-inflammatory drugs, **283–286**
 pharmacokinetics of, 401*t*
 toxicity of, 284*t*
- Tolterodine. *See also* anticholinergic agents, **84–86**
 pharmacokinetics of, 401*t*
 toxicity of, 85*t*
- Toluene, **357–359**
 exposure limits for, 358, 620*t*
 hazard summary for, 620*t*
 hypokalemia caused by, 38*t*
 kinetics of, 358
 toxicity of, **357–359**
- Toluene 2,4-diisocyanate (TDI), **232–233**
 asthma caused by, 520
 exposure limits for, 232, 621*t*
 hazard summary for, 621*t*
 toxicity of, **232–233**
- m*-Toluidine, hazard summary for, 621*t*
- o*-Toluidine, hazard summary for, 621*t*
- p*-Toluidine, hazard summary for, 621*t*

- Toluol (toluene), **357–359**
 exposure limits for, 358, 620*t*
 hazard summary for, 620*t*
 hypokalemia caused by, 38*t*
 kinetics of, 358
 toxicity of, **357–359**
- Tomato leaves, 317*t*. *See also* plants, **309–319**
- Tonka bean, 317*t*. *See also* plants, **309–319**
- Tonocard. *See* tocinide, 79–80, 79*t*
- Toothpaste
 with fluoride, **200–201**
 without fluoride, 287*t*. *See also* low-toxicity products, **286**
- Topamax. *See* topiramate, 86*t*, 87
- Topiramate. *See also* anticonvulsants, **86–87**
 pharmacokinetics of, 401*t*
 toxicity of, 86*t*, 87
- Topoisomerase inhibitors. *See also* antineoplastic agents, **100–107**
 toxicity of, 100, 104*t*
- Topotecan. *See also* antineoplastic agents, **100–107**
 toxicity of, 104*t*
- Toprol. *See* metoprolol, 132*t*
- Toradol. *See* ketorolac, 284*t*
- Toremifene. *See also* antineoplastic agents, **100–107**
 toxicity of, 103*t*
- Torsade de pointes, 14, 15*t*
 droperidol and haloperidol causing, 14*t*, 25, 452
 drugs and toxins causing, 14, 14*t*
 terfenadine or astemizole causing, 14*t*, 96
 treatment of, 15
 isoproterenol for, 15, 458–459
 magnesium for, 463–464
 tricyclic antidepressants causing, 14*t*, 91, 92
 type Ia antiarrhythmic drugs causing, 324, 325
- Torsemide
 pharmacokinetics of, 401*t*
 toxicity of, 188*t*
- Total clearance, effectiveness of enhanced elimination and, 55, 56*t*
- Toxalbumin. *See also* plants, **309–319**
 toxicity of, 310*t*
- Toxaphene (chlorinated camphene). *See also* chlorinated hydrocarbons, **161–162**
 hazard summary for, 548*t*
 toxicity of, 161*t*
- Toxicodendron* spp, 315*t*, 316*t*. *See also* plants, **309–319**
- Toxicology screening, **40–45**
 agents commonly included in, 41*t*, 42*t*
 agents not included in, 42*t*
 approach to, 45, 45*t*
 in drug-assisted assault, 64–65, 64*t*
 interferences in, 43–44*t*
 limitations of, 40–42
 uses for, 42–45
- Toxogonin. *See* obidoxime, 492
- Toyon leaves, 317*t*. *See also* plants, **309–319**
- Tracrium. *See* atracurium, 473*t*, 475
- Tramadol, 287–289, 289*t*. *See also* opiates/opioids, **286–291**
 monoamine oxidase inhibitor interaction and, 270*t*
 pharmacokinetics of, 402*t*
 toxicity of, 287–289, 289*t*
- Trandate. *See* labetalol, **459–460**
- Trandolapril, pharmacokinetics of, 402*t*
- Transdermal nicotine patches. *See also* nicotine, **277–278**
 toxicity of, 277
- Transderm Scop. *See* scopolamine, 85*t*, 373, 376
- Transfusion exchange
 for arsine gas poisoning, 120, 121
 for iron poisoning, 231
 for methemoglobinemia, 263
 for nitrate/nitrite overdose, 280
 for warfarin overdose, 380
- Transport, for victims of hazardous materials incident, 516
- Tranxene. *See* clorazepate, 130*t*
- Tranylcypromine. *See also* monoamine oxidase inhibitors, **269–271**
 abdominal x-ray showing, 46*t*
 pharmacokinetics of, 402*t*
 toxicity of, 269–271
- Trastuzumab. *See also* antineoplastic agents, **100–107**
 toxicity of, 104*t*
- Trauma
 occupational causes of, 522*t*
 rhabdomyolysis associated with, 27*t*
- Trazodone, 88. *See also* antidepressants, noncyclic, **88–90**
 monoamine oxidase inhibitor interaction and, 89, 270*t*
 pharmacokinetics of, 89, 402*t*
 toxicity of, 88, 88*t*, 89
- Tremolite (asbestos), **121–122**
 exposure limits for, 121, 538*t*
 hazard summary for, 538*t*
 toxicity of, **121–122**
- Tretinoin (retinoic acid). *See also* antineoplastic agents, **100–107**
 teratogenic effects of, 59*t*
 toxicity of, 105*t*
- Triaminic Cold Syrup. *See* chlorpheniramine, 97*t*
 phenylpropanolamine, **320–322**
- Triaminic DM. *See* dextromethorphan, **183–184**
 phenylpropanolamine, **320–322**
- Triaminic Expecto-rant. *See* guaifenesin, 287*t*
 phenylpropanolamine, **320–322**
- Triaminic Nite Lite. *See* chlorpheniramine, 97*t*
 dextromethorphan, **183–184**
 pseudoephedrine, **320–322**
- Triaminic Multisymptom Cold Syrup. *See* chlorpheniramine, 97*t*
 dextromethorphan, **183–184**
 phenylpropanolamine **320–322**
- Triamterene. *See also* diuretics, **187–189**
 pharmacokinetics of, 402*t*
 toxicity of, 188*t*
- Triatomic oxygen (ozone). *See also* gases, irritant, **213–215**
 exposure limits for, 214*t*, 600*t*
 hazard summary for, 600*t*
 job processes associated with exposure to, 521*t*
 toxicity of, 214*t*
- Triavil (amitriptyline with perphenazine). *See* amitriptyline, 88*t*, 90
 perphenazine, 107*t*
- Triazolam. *See also* benzodiazepines, **129–131**, **415–418**
 pharmacokinetics of, 402*t*
 toxicity of, 129, 130, 130*t*
- 3-amino-1,2,4-Triazole (amitrole), hazard summary for, 536*t*
- Triazophos. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
- Tribromomethane (bromoform), hazard summary for, 542*t*
- Tribufos. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
- Tributyl phosphate, hazard summary for, 621*t*
- Trichlorfon. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 292*t*
- Trichlormethiazide. *See also* diuretics, **187–189**
 pharmacokinetics of, 402*t*
 toxicity of, 188*t*
- Trichloroacetic acid, hazard summary for, 621*t*
- 1,2,4-Trichlorobenzene, hazard summary for, 621*t*
- Trichloroethane, **359–361**
 exposure limits for, 359–360
 toxicity of, **359–361**
- 1,1,1-Trichloroethane (methyl chloroform)
 exposure limits for, 359–360, 622*t*
 hazard summary for, 622*t*
 toxicity of, 359–361
- 1,1,2-Trichloroethane
 exposure limits for, 359–360, 622*t*
 hazard summary for, 622*t*
 toxicity of, 359–361
- 2,2-bis(*p*-methoxyphenyl)-1,1,1-Trichloroethane (methoxy-chlor). *See also* chlorinated hydrocarbons, **161–162**
 hazard summary for, 587*t*
 toxicity of, 161*t*

- Trichloroethanol (chloral hydrate). *See also* sedative-hypnotics, **335–337**
 abdominal x-ray showing, 46*t*
 in drug-assisted assault, 64*t*
 elimination of, 56*t*
 esmolol for overdose of, 336, 443–444
 odor caused by, 32*t*
 pharmacokinetics of, 384*t*
 propranolol for overdose of, 336, 496–497
 toxicity of, 335*t*, 336
 in toxicology screens, 41*t*
 ventricular arrhythmias caused by, 14*t*, 15, 336
 volume of distribution of, 56*t*, 384*t*
 warfarin interaction and, 379*t*
- Trichloroethylene (trichloroethene), **359–361**
 exposure limits for, 360, 622*t*
 hazard summary for, 622*t*
 toxicity of, **359–361**
- Trichlorofluoromethane (Freon 11)
 hazard summary for, 622*t*
 toxicity of, 209–210
- Trichloromethane (chloroform), **154–155**
 acetylcysteine for poisoning caused by, 155, 405–407
 exposure limits for, 154, 550*t*
 hazard summary for, 550*t*
 methyl (1,1,1-trichloroethane)
 exposure limits for, 359–360, 622*t*
 hazard summary for, 622*t*
 toxicity of, 359–361
 toxicity of, **154–155**
- Trichloronaphthalene, hazard summary for, 622*t*
- Trichloronitromethane (chloropicrin), hazard summary for, 551*t*
- 2,4,5-Trichlorophenoxyacetic acid (2,4,5-T)
 in Agent Orange, 164
 hazard summary for, 623*t*
 toxicity of, 164–165
- 4-amino-3,5,6-Trichloropicolinic acid (picloram), hazard summary for, 605*t*
- 1,1,2-Trichloro-1,2,2-trifluoroethane (Freon 113)
 hazard summary for, 623*t*
 toxicity of, 209–210
- Trichoderma* spp. *See also* molds, **267–269**
 toxicity of, 267
- Trichothecene mycotoxins, as biological weapons, 370*t*. *See also* warfare agents, biological, **367–372**
- Tricyclic antidepressants, 88*t*, **90–93**
 atrioventricular (AV) block caused by, 10*t*, 91
 bicarbonate for overdose of, 15, 92, 419–420
 bradycardia caused by, 10*t*, 91
 coma caused by, 19*t*, 90, 91
 dyskinesias caused by, 26*t*
 hypertension caused by, 18*t*, 90
 hyperthermia caused by, 21*t*, 91
 hypotension caused by, 16*t*, 90, 91
 hypothermia caused by, 20*t*
 hypoxia caused by, 7*t*
 mydriasis caused by, 30*t*
 pharmacokinetics of, 90
 physostigmine contraindicated in overdose of, 13, 92, 490
 QRS interval prolongation caused by, 11, 11*t*, 12*t*, 91
 rhabdomyolysis caused by, 27*t*, 91
 seizures caused by, 23*t*, 90, 91, 92
 stupor caused by, 19*t*
 tachycardia caused by, 13, 13*t*, 14*t*, 15, 90, 91
 toxicity of, 88*t*, **90–93**
 in toxicology screens, 41*t*, 91–92
 interferences and, 44*t*
 ventilatory failure caused by, 6*t*
 ventricular arrhythmias caused by, 14*t*, 15, 90
- Tridihexethyl. *See also* anticholinergic agents, **84–86**
 toxicity of, 85*t*
- Tridymite (silica), hazard summary for, 611*t*
- Trien. *See* triethyl tetramine dihydrochloride, 176
- Triethylamine, hazard summary for, 623*t*
- Triethylene glycol. *See also* glycols, **194–198**
 toxicity of, 196*t*
- Triethyl tetramine dihydrochloride, for copper poisoning, 176
- Trifluoperazine. *See also* antipsychotic drugs, **107–109**
 abdominal x-ray showing, 46*t*
 pharmacokinetics of, 402*t*
 toxicity of, 107*t*
 in toxicology screens, 41*t*
- Trifluorobromomethane, hazard summary for, 623*t*
- Trifluoromethane (Freon 23), hazard summary for, 623*t*
- Trifluridine. *See also* antiviral and antiretroviral agents, **111–115**
 toxicity of, 112*t*
- Trihexyphenidyl. *See also* anticholinergic agents, **84–86**
 pharmacokinetics of, 402*t*
 toxicity of, 85*t*
 in toxicology screens, 41*t*
- 1,2,3-Trihydroxybenzene (pyrogallol), hazard summary for, 609*t*
- Triiodothyronine (liothyronine/T₃). *See also* thyroid hormone, **354–356**
 pharmacokinetics of, 392*t*
 toxicity of, 356–357, 356*t*
- Trilafon. *See* perphenazine, 107*t*
- Trileptal. *See* oxcarbazepine, 396*t*
- Trimazosin
 pharmacokinetics of, 402*t*
 toxicity of, 365–366
- Trimellitic anhydride
 hazard summary for, 623*t*
 job processes associated with exposure to, 521*t*
- Trimepazine. *See also* antihistamines, **96–98**
 abdominal x-ray showing, 46*t*
 pharmacokinetics of, 402*t*
 toxicity of, 97*t*
- Trimethacarb. *See also* organophosphates and carbamates, **291–295**
 toxicity of, 293*t*
- Trimethadione, teratogenic effects of, 59*t*
- Trimethobenzamide/trimethobenzmine. *See also* antipsychotic drugs, **107–109**
 pharmacokinetics of, 402*t*
 toxicity of, 107*t*
- Trimethoprim. *See also* antibacterial agents, **81–84**
 leucovorin calcium for overdose of, 81, 460–461
 pharmacokinetics of, 402*t*
 toxicity of, 81, 84*t*
- 3,4,5-Trimethoxyphenethylamine (mescaline), 248*t*. *See also* hallucinogens, **247–249**
 toxicity of, 248*t*

Antiemetics, Prokinetic Agents and Drugs for Irritable Bowel Syndrome

Vomiting means expulsion of gastric contents through mouth due to mass antiperistalsis. It is often preceded by *nausea* which means an uneasy feeling in anticipation of vomiting. In between these two stages there is a series of weaker and unproductive vomiting movements called *retching*. Vomiting can be a valuable, life saving, physiological response to the ingested toxic substances. However, it is also an unwanted side effect of radiation and cancer chemotherapeutic agents. It also occurs in early pregnancy, during migraine attack and due to motion sickness. Vomiting results due to stimulation of vomiting center (VC) which is located in the lateral medullary reticular formation. Efferent fibres from this center, when stimulated, cause stimulation of phrenic nerve supplying to diaphragm and of somatic nerve supplying the abdominal muscles to promote emesis.

EXCITING INPUTS AND NEUROTRANSMITTER ROLE IN EMESIS

Proper pharmacological management of vomiting requires understanding of neurotransmitter involvement in emesis (Fig.28.1).

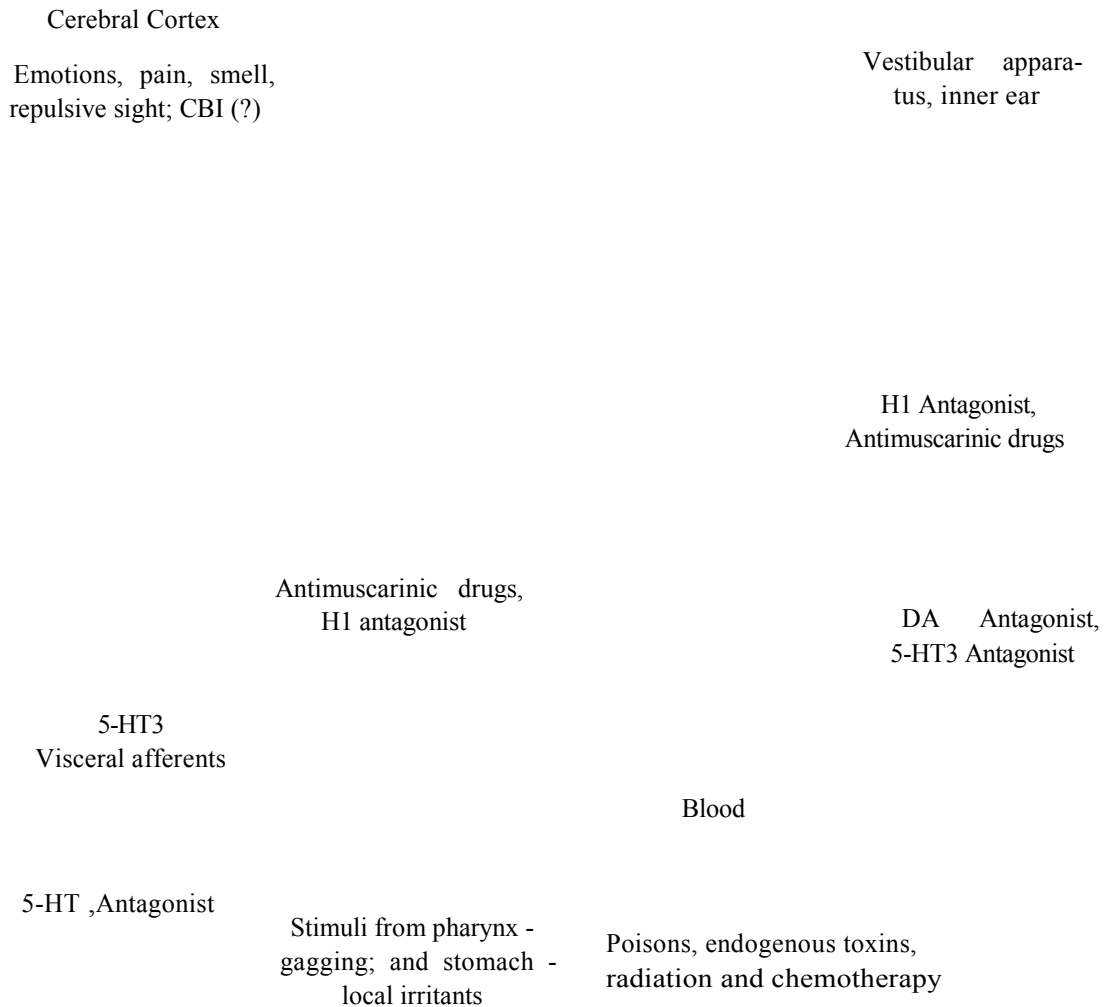

1. The major afferent inputs to vomiting centre are routed through chemoreceptor trigger zone (CTZ; or area postrema) which is located at the end of IV ventricle. Since CTZ lies outside of the BBB, it can freely monitor for toxic and emetogenic stimuli circulating in blood or CS F and can relay this information to VC to trigger nausea and vomiting. The CTZ is rich in dopamine (D₂), serotonin (5-HT₃), muscarinic (M₁), histamine (H₁), opioid (μ) and NK₁ receptors which could be the targets for existing and newer antiemetic drugs.
2. The vestibular apparatus generates impulses during motion sickness which reach VC mainly *via* cerebellum. Vestibular apparatus is rich in muscarinic (M₁) and histaminic (H₁) receptors.
3. Vagal and splanchnic afferents in the GIT mucosa are rich in 5-HT₃ receptors. Irritation of GIT mucosa by irritants, chemotherapeutic agents, radiation therapy, endogenous toxins and poisons lead to a release of mucosal serotonin from enterochromaffin-like cells (ECL cells) which activate these 5-HT₃ receptors. This propagates vagal afferent inputs to nucleus tractus solitarius (NTS) for onward transmission to VC. NTS is rich in histamine (H₁), cholinergic (M₁) and serotonin (5-HT₃) receptors.
4. Transmitter mediators in the cerebral cortex (higher centers) are poorly understood. However, cortical cannabinoid (CB₁) receptors have been implicated. Muscarinic (M₁), histaminic (H₁), serotonin (5-HT₃) and Neurokinin-1 (NK₁) receptors have been identified at the vomiting center. Histamine through activation of H₁ receptors has a permissive role to play, as an excitatory neurotransmitter, in all sorts of emesis.

TYPES OF EMESIS AND ANTIEMETIC DRUGS

Motion Sickness

Motion sickness can result during space flights, taking off and landing of an aeroplane, viewing of a moving horizon or waves of the sea from the deck of a rolling ship. Since it is a labyrinthine vomiting *via* stimulation of vestibular nuclei, one can use a H₁-receptor antagonist or a centrally acting anticholinergic drug (see Fig. 28.1).

Hyoscine (or scopolamine) transdermal patch or 0.6 mg orally 30-60 min before journey, can be used prophylactically or 0.2 mg I.M. can be used if motion sickness has started. Side effects are least at this dose but higher doses may cause common anticholinergic effects like blurred vision, dryness of mouth, cycloplegia, sedation and sleepiness (For preparations, see Ch.11).

Key: CTZ—Chemoreceptor trigger zone; NTS—Nucleus tractus solitarius

Neurotransmitters Involved in the Process of Vomiting, and Probable Sites of Action of Antiemetic Drugs.

H1 antagonists (Ch. 24), with anticholinergic properties are particularly useful for prevention or treatment of motion sickness. *Diphenhydramine* (or *dimenhydrinate*), *cyclizine* or *meclizine* are commonly used drugs for the prevention of motion sickness and for treatment of vertigo due to labyrinth dysfunction. A non-neuroleptic phenothiazine, *promethazine*, because of its antihistaminic-anticholinergic properties also possesses potent antinotion sickness activity. As discussed earlier,

these drugs are associated with common anticholinergic side effects besides sedation. *Cinnarizine* is another antivertigo drug which can also be used for the prevention of motion sickness. It is an antihistamine having additional anticholinergic, antiserotonin and Ca²⁺ channel blocking properties. By inhibiting the influx of Ca²⁺ from endolymph into the vestibular apparatus it blocks further mediation of labyrinthine reflexes.

Morning Sickness (vomiting during pregnancy)

It results in the first trimester of pregnancy due to the effect of increased oestrogen levels on CTZ. It persists for few weeks and then subsides. However, in some cases there may be hyperemesis gravidarum leading to dehydration which needs proper drug treatment, although drugs should be avoided unless necessary.

Among antihistamines, *doxylamine*, *cyclizine* or *meclizine* can be used but doxylamine (doxinate) is the safest as it has been cleared of teratogenic potential. *Vitamin B6 (pyridoxine)* in high doses (20–60 mg/day) is quite effective. Vitamin B₆ serves as a cofactor for the enzyme glutamate decarboxylase and thus increases the synthesis of GABA which according to some reports serves as inhibitory neurotransmitter at CTZ. D₂ receptor antagonists, though work effectively, are better avoided because of their teratogenic potential.

Chemotherapy or Radiation Induced Nausea and Emesis (CIE)

Anticancer drugs like cisplatin may induce emesis by directly activating 5-HT₃ receptors in CTZ or may bind to vagal and splanchnic 5-HT₁ receptors to send emetogenic signals to VC through NTS. The most effective agents for CIE are, therefore, 5-HT₃ antagonists such as *ondansetron*, *granisetron*, *dolasetron*, *tropisetron* and *palonosetron*. These drugs block 5-HT₃ receptors both peripherally (on vagal nerve terminals) as well as centrally (NTS and CTZ). *Palonosetron* is the most potent 5-HT₃ antagonist (VA 40 hrs), given I.V. only.

These drugs are most effective when given by I.V. route (as single dose), 30 min prior to chemotherapy: ondansetron 0.15 mg/kg, dolasetron 1.8 mg/kg, granisetron 10 µg/kg and palonosetron 0.25 mg. These doses may be repeated every 24 hrs. For less emetogenic chemotherapeutic agents and for radiotherapy, the oral doses may be effective: ondansetron 8 mg BD, granisetron 2 mg/day and dolasetron 100 mg/day. The efficacy of 5-HT₃ antagonists is enhanced by the concurrent administration of *dexamethasone* (basis unknown)

or *prochlorperazine* / *metoclopramide* / *domperidone* (for additional D₂ blocking effects) and/or *diazepam* (for enhancing the inhibitory effects of GABA on CTZ—see above). Very efficacious combination, recently approved, is with *dexamethasone* and *aprepitant* (an NK₁ receptor antagonist, see below).

5-HT₃ antagonists have an excellent safety profile. However, headache, constipation, abdominal discomfort and rashes (especially after I.V. injection) may occur. Dolasetron may prolong QT interval and should be avoided in patients having prolonged QT. No significant drug interactions have been reported with these drugs.

The nausea-vomiting due to cisplatin has two phases: *an acute phase* (within 24 hrs after chemotherapy), which can be treated with 5-HT₃ antagonists alone or with other drug combinations (see above); other is a *delayed phase* (on 2nd day or afterwards). 5-HT₃ antagonists even with adjuvant drugs are not very effective against this phase of emesis. Lately, NK₁ subtype receptors for substance-P, a tachykinin group of neurotransmitters, have been identified on vagal fibres innervating NTS and area postrema. Even more recently, some synthetic non-peptide antagonist of NK₁ receptor (*aprepitant* oral or *fosaprepitant* I.V.) have been developed and found to be very effective single agent in the prevention of delayed phase of nausea-vomiting after cisplatin therapy.

Usual doses are: *aprepitant* 125 mg orally or *fosaprepitant* 115 mg I.V. given 1 hr before chemotherapy followed by oral *aprepitant* 80 mg daily for next 2 days after chemotherapy. *Fosaprepitant* is a prodrug of *aprepitant*.

For many years, *metoclopramide* (5–10 mg TDS oral or I.M. every 6 hrs), a dopamine (D₂) receptor blocker acting on CTZ, enjoyed the status of most widely used antiemetic drug to treat chemotherapy induced or radiation induced nausea-vomiting. Later it was found that its prokinetic effects (see below for details), also contribute to its effectiveness in chemotherapeutic induced nausea-vomiting. *Metoclopramide* efficacy is improved while incidence of side effects is reduced when it is combined with other agents, like *diphenhydramine* (a H₁ receptor

antagonist) + *dexamethasone* (a corticosteroid) + *lorazepam/diazepam* (an antianxiety agent).

Domperidone (10-40 mg TDS oral), is another D₂ receptor antagonist with antiemetic and prokinetic effects like that of metoclopramide. Though its antiemetic efficacy is lesser than metoclopramide, its principal advantage over metoclopramide is the lack of extrapyramidal CNS side effects: restlessness, dystonias, and parkinsonian symptoms because of its poor penetration to CNS. The efficacy of domperidone in chemotherapy/radiation-induced emesis is improved when it is combined with other agents like *prochlorperazine* (a phenothiazine group of neuroleptic-antiemetic) + *diphenhydramine* (a H₁ blocker) + *dexamethasone* (a corticosteroid).

Postoperative Vomiting

Postoperative nausea-vomiting are complications in 30-40% of patients receiving general anaesthesia.

Women undergoing gynaecological surgery are particularly at a greater risk (60-80%) in experiencing such type of vomiting. 5-HT₃ receptor antagonists because of their better reliable index, are generally preferred to prevent or treat postoperative nausea and vomiting. Antihistamines (promethazine and diphenhydramine) and the prokinetic drugs with D₂ receptor blocking action (metoclopramide and domperidone) are also used but with a limited success. Phenothiazines, which are primarily used as antipsychotic agents, can also be used for their antiemetic properties in postoperative nausea and vomiting. The most commonly used agents are *prochlorperazine* (5-25 mg oral, TDS or 12.5 mg, I.V.) and *promethazine* (12.5-25 mg BD or TDS oral or I.V.). Prochlorperazine has D₂ receptor and muscarinic receptor blocking action. Promethazine is a potent antihistaminic and anticholinergic drug.

Butyrophenone group of antipsychotics (e.g., *droperidol*) can also be used to treat postoperative nausea and vomiting by giving I.V. or I.M. injection. In antiemetic doses it is extremely sedating and both prochlorperazine as well as droperidol, can precipitate extrapyramidal side effects and postural hypotension. Droperidol should not be used in patients who show prolongation of QT interval in their ECG because

further prolongation of QT interval may lead to tachyarrhythmias, though rarely.

Vomiting of Varied Origin and Adjuvant Antiemetics

Drug-induced vomiting, and raised intracranial pressure induced emesis are some examples of vomiting of varied origin whose pharmacotherapy is still unresolved.

Vomiting in patients due to brain injury, cerebral tumour or hydrocephalus increases CSF pressure which is possibly responsible for neurotransmitter-related activation of receptors present on CTZ. However, which neurotransmitter is responsible to cause this type of emesis is not known, except for 5-HT because 5-HIAA levels in CSF are raised in patients with raised intracranial pressure. Recently, role of CB₁ receptors has also been implicated.

Nabilone and *dronabinol* (delta-9-THC) are analogues of 9-tetrahydrocannabinol (9-THC). The latter is the active principle of *Cannabis sativa*, and has antiemetic properties but disorienting and 28 hallucinogenic effects limit its clinical usefulness. Nabilone and dronabinol are however less hallucinogenic with better antiemetic efficacy against moderately emetogenic chemotherapeutic agents. They probably act by stimulating CB₁ subtype of cannabinoid receptors present on neurons around vomiting center. Since their antiemetic effect is antagonised by naloxone, it is believed that they might be inhibiting endorphins (or [1. receptors) in vomiting centre. Dronabinol is administered at an initial dose of 5 mg/m² given 2 hrs before chemotherapy and then at every 4 hrs afterwards, for a total of 4 to 6 doses. It can also be used for vomiting refractory to other antiemetics but it is not helpful in emesis due to raised intracranial pressure where correction of cause is more beneficial. Because of its appetite stimulant action it is also used in AIDS-related anorexia. A combination therapy with phenothiazines (*prochlorperazine*), provides the synergistic antiemetic action with reduced side effects of both the drugs. *Adverse effects* of nabilone and dronabinol include euphoria, dysphoria, sedation, hallucination, dry mouth, increased appetite, tachycardia and orthostatic hypotension.

EMETICS

Emetics are used for deliberate production of emesis for treatment. They may act centrally by stimulating CTZ or may work as reflex emetics. Commonly used emetics are *apomorphine* and *ippecacuanha*. *Apomorphine* is a semisynthetic morphine derivative which stimulates dopamine receptors at CTZ. It is administered parenterally (S.C. or LM.). If vomiting does not occur, the second dose should be avoided. Larger doses produce convulsions and respiratory depression. *Ipecacuanha* (syrup ipecac) is procured from the roots of *Cephalis cuanha*. It stimulates CTZ and also works as a reflex emetic (active principle: emetine). It is administered orally and is safer than apomorphine. Ingestion of *sodium chloride solution* and *mustard powder* also serves as domestic substances to produce emesis.

Emetics are contraindicated in hypertension, peptic ulcer, pulmonary tuberculosis, uraemia and pregnancy. Emetics should be avoided in case of corrosive poisons because an increase in intragastric pressure may lead to perforation. These should also be avoided in cases of poisoning due to petroleum products because of the danger of producing lipid aspiration pneumonia.

PROKINETIC DRUGS

Prokinetic agents (1) stimulate GIT motility; (2) increase lower oesophageal sphincter pressure (hence useful for GERD); (3) speed-up gastric emptying (hence useful for gastroparesis); (4) stimulate small intestine (hence beneficial for postoperative paralytic ileus and colonic pseudo-obstruction); and (5) enhance colonic transit (hence useful for treating constipation). In current practice, prokinetic agents mean the drugs that enhance the coordinated activity among the various segments of the gut to propel the luminal contents.

Physiology of Gut Motility

The Enteric Nervous System (ENS) is organised into two types of network of neurons called plexus (Fig. 10.11). One is myenteric (Auerbach's) plexus which is found between the circular and longitudinal

muscle layers and is responsible for motor control (peristaltic reflex). Another is submucosal (Meissner's) plexus which is located below mucosa (epithelium) and regulates secretions. The primary neurotransmitter of the myenteric motor neuron is ACh (Fig. 28.2).

These neurons receive inputs from both ascending and descending interneurons (relay system) which are of two types: excitatory (ACh) and inhibitory (NO). Mucosal stimulation leads to release of serotonin from enterochromaffin cells (EC) and by neurons of myenteric plexus. It acts as an autacoid and affects both motor activity as well as secretion. Serotonin action appears to be mediated

neuron

3

Key: EC—Enterochromaffin cells;
ACh—acetylcholine; DA—dopamine;
METO—metoclopramide; DOM—domperidone;
CISAP—cisapride; TEGA—tegaserod;
NO—nitric oxide; M₃, D₂, 5-HT₃ and
5-HT₄ are respective receptors;
IEI—Inhibitory ENS interneuron;
EEI—Excitatory ENS interneuron.

Modulation of Gastrointestinal
Motility by Prokinetic Agents.

principally *via* 5-HT₃ and 5-HT₄ receptors which are present on the inhibitory and the excitatory interneurons, respectively, that synapse with cholinergic myenteric motor neuron. The latter neuron (i.e., excitatory) when excited induces smooth muscle contraction *via* release of ACh and when the inhibitory neuron is activated there is relaxation *via* dampening the release of ACh from primary cholinergic motor neuron. Dopaminergic neurons also make a synapse with the primary cholinergic neuron (Fig. 28.2). Dopamine (DA) acting through D₂ receptors present on the cholinergic neurons inhibits the release of ACh *via* heterotropic presynaptic receptor interaction (see Ch. 10).

Motilin is another polypeptide hormone secreted by ECL cells of duodenum and jejunum. Motilin receptors have been identified on intestinal smooth muscle cells, activation of which induces potent contractile movements in the upper gastrointestinal tract, increases lower esophageal sphincter (LES) tone and stimulates pepsin secretion.

Metoclopramide

Metoclopramide is a D₂ receptor antagonist, 5-HT₃ receptor antagonist and 5-HT₄ receptor agonist. Due to blockade of D₂ receptors, dopamine loses its inhibitory control over ACh release from the primary cholinergic neuron in myenteric plexus (Fig. 28.2). It has now been ascertained that central *la*, action of metoclopramide is clearly responsible for its antiemetic effects and that its prokinetic activity contributes only partly. The major mechanism responsible for its prokinetic effects is *via* activation of 5-HT₄ receptors present on excitatory interneurons (see earlier text and Fig. 28.2), which enhances ACh release from primary cholinergic neurons in myenteric plexus. Thus it increases LES tone, facilitates gastric peristalsis and speeds-up gastric emptying. However, colonic motility remains unaffected (not enhanced). 5-HT₃ receptors on inhibitory interneurons are also blocked by metoclopramide but in high doses only. Thus the release of NO is also suppressed, which indirectly facilitates ACh release from the primary motor neuron. However, this mechanism seems to contribute little towards its prokinetic effects.

Metoclopramide is used as antiemetic (see earlier text) and as gastrokinetic agent to accelerate gastric emptying prior to giving emergency general anaesthesia in case the patient has taken food less than 4 hrs before, to facilitate duodenal intubation and to relieve diabetes associated gastric stasis. Metoclopramide also affords relief in mild gastroesophageal reflux disease (GERD) but PPIs/H₂ blockers are more preferred (Ch. 27) because it is not effective in erosive oesophagitis. The drug may also succeed in stopping persistent hiccups.

Metoclopramide, being a central/peripheral D₂ receptor blocker, produces sedation, muscle dystonias and in higher doses may induce extrapyramidal side effects, galactorrhoea (in females) and gynaecomastia (in males).

Domperidone

Its mechanism of action is similar to metoclopramide. It is a peripheral D₂ receptor blocker which is structurally related to haloperidol (but has got no antipsychotic activity). It is pharmacologically related to metoclopramide, but its antiemetic efficacy is lower than that of metoclopramide. It is also used to prevent the emetic side effects of levodopa or bromocriptine without affecting their therapeutic efficacy as antiparkinsonism drugs. Other indications are also similar to metoclopramide (see above).

Cisapride, Mosapride, Zacopride and Renzapride

This group of prokinetic drugs is devoid of D₂ receptor

blocking properties; nor do they act on CTZ and hence they facilitate GIT motility with no antiemetic effects. These drugs act mainly through 5-HT₄ agonist

action which promotes ACh release from myenteric plexus aided by 5-HT₃ antagonism which depresses inhibitory transmission and thus also facilitates ACh release indirectly from myenteric plexus (Fig. 28.2).

Cisapride (10-20 mg oral TDS) facilitates gastric motility, throughout the GIT including the colon, hastens gastric emptying, improves LES tone and oesophageal peristalsis. Primary indication for cisapride is GERD (but PPIs/H₂ blockers are preferred). Other indications include non-ulcer

dyspepsia, impaired gastric emptying and constipation, though usefulness is debatable.

Adverse effects include abdominal cramps and diarrhoea. Though side effects are mild, the safety of cisapride has been questioned as it prolongs the QT interval and predisposes to ventricular fibrillation in high doses. It is also a cytochrome CYP3A4 enzyme inhibitor. Hence when coadministered with the drugs which also inhibit the same enzyme, significant rise in cisapride plasma levels results that may lead to prolongation of QT interval and ventricular arrhythmias. Such drugs include fluconazole, ketoconazole, erythromycin, clarithromycin and some antidepressants like nefazodone. For this reason it has been withdrawn in USA but is still available in several countries, including India.

The newer congeners like *mosapride* (5 mg oral TDS), *renzapride* and *zacopride* do not cause QT prolongation or arrhythmias. Their pharmacological characteristics, mode of action, indications and side effects are similar to cisapride (except QT prolongation).

Macrolides (motilin agonists)

Macrolide antibiotics, like *erythromycin*, *azithromycin* and *clarithromycin*, directly stimulate motilin receptors on GIT smooth muscle (see above), and promote upper gastrointestinal motility, increase the LES tone and stimulate small intestinal contractility. In contrast to cisapride they have no effect on colonic motility. A standard dose of erythromycin used for gastric stimulation is 40 mg I.V. or 200-250 mg orally TDS. It can be used to improve gastric emptying in patients with diabetic gastroparesis and in small bowel dysmotility such as seen in pseudo-obstruction. However, tolerance develops rapidly to its prokinetic effects, and its antibiotic effects are absolutely undesirable in gastrokinetic context.

Miscellaneous Agents

- *Prucalopride* is a safest analogue of cisapride and is a highly selective 5-HT₄ receptor agonist. It is used to treat severe constipation but its long-term efficacy and safety has not been established.

- *Loxiglumide* is a CCK₁ receptor antagonist that has been developed recently to improve and speed

up gastric emptying and GIT motility. Cholecystokinin (CCK) is a gastrointestinal hormone that is released from the intestine in response to meal, and slows down gastric emptying (Ch.27).

DRUGS FOR IRRITABLE BOWEL SYNDROME (IBS)

Irritable bowel syndrome (IBS) is manifested by a variety of gastrointestinal symptoms including disordered bowel habits (constipation, diarrhoea or both) in association with abdominal pain and bloating. Hence the patients generally fall into two categories: *Constipation-dominant-IBS* or *diarrhoea-dominant-IBS*.

The mainstay of the treatment for IBS is directed towards relieving abdominal pain and discomfort plus improving the bowel disorder. For patients of diarrhoea-dominant IBS, antidiarrhoeal agents (see below) are used while for patients of constipation-dominant IBS, fibre supplements are administered orally with enough water-intake. This reduces strain during defaecation by softening of the stool. However, if bloating or abdominal discomfort is exacerbated, osmotic laxative, e.g., milk of magnesia (Ch. 29) may be substituted in place of fibre diet. Several other agents, that are generally used to treat IBS, are discussed below.

Antidiarrhoeal-Antispasmodic Drugs

In patients of diarrhoea-dominant IBS, *loperamide* or *diphenoxylate* are preferred over other opioid antidiarrhoeals like codeine, to avoid CNS side effects (Ch. 37). *Fedotozine* is a recently developed opioid which is peripherally μ -receptor selective antagonist. Being devoid of CNS effects, it can be given to chronic patients in whom prolonged medication is anticipated. To provide relief from abdominal pain or discomfort "antispasmodics" such as *dicyclomine* and *hyoscyamine* are commonly used. These agents work primarily by inhibiting M₃ cholinergic receptors in the enteric plexus and on smooth muscles. At low doses these have minimal side effects but at higher doses they exhibit significant anticholinergic side effects such as

dryness of mouth, blurred vision, urinary retention and constipation. However, their efficacy in IBS is doubtful and hence these are not used that frequently. *Mebeverine* is a reserpine analogue which directly suppresses colonic hypermotility. It is devoid of usual anticholinergic side effects observed with commonly used antispasmodics.

Antidepressants

In recent years, an increasing emphasis has been laid on the pharmacological treatment of visceral sensitivity towards pain in patients of IBS. Low doses of tricyclic antidepressants (e.g., *amitriptyline* or *desipramine* 10-25 mg OD) do not affect mood but hamper central processing of visceral afferent information. Their anticholinergic properties also help in reducing gastrointestinal motility and secretion which in turn reduces the frequency and liquidity of stools.

5-HT₃ Receptor Antagonists

Although the biological basis of visceral hyperalgesia in IBS patients is not clear, a possible role of 5-HT₃ receptor has been suggested. Of all the currently identified 5-HT receptors, only 5-HT₃ receptor is an ionotropic receptor belonging to the nicotinic-acetylcholine super-family of receptors. 5-HT₃ receptors in GIT activate visceral afferent pain sensation from the gut to CNS. Blockade of 5-HT₃ inhibits colonic motility by decreasing the ion-permeability besides inhibiting unpleasant pain sensation.

Alosetron is a potent and selective 5-HT₃ antagonist that has been used to treat women with diarrhoea-dominant abdominal pain-associated IBS, who have failed to respond to conventional therapy. Somehow, the efficacy in man has not been established. In dosage of 1 mg OD or BD, it reduces all symptoms of IBS, including pain and diarrhoea. Like ondansetron, it prolongs total colonic transit time by inhibiting colonic hypermotility. However, like ondansetron it is not used as antiemetic. On the other hand, ondansetron is not used for treating IBS. This relative difference between these two 5-HT₃ antagonists seems paradoxical and needs elucidation.

Usual side effects of alosetron are constipation, sleep disorders and abdominal discomfort. However, constipation induced by alosetron may result into fatal ischaemic colitis. The drug has to be discontinued immediately if constipation or symptoms of ischaemic colitis occur. Reinitiation of the drug after treating ischaemic colitis is also not advisable. From the year 2000, the FDA has restricted its use in women with diarrhoea-dominant IBS not responding to other therapies.

5-HT₄ Receptor Agonists

Tegaserod is the peripheral 5-HT₄ receptor agonist that binds to mucosal 5-HT₄ receptors and promotes gastric emptying and facilitates small and large bowel transit. *Tegaserod* (6 mg BD) is being used for the treatment of patients with constipation-predominant IBS. It also reduces sensitivity as well as severity of pain and bloating in such patients. However, its bioavailability is only 10% and food further reduces its bioavailability. Hence, it should be taken before meals. It should be avoided in patients having severe hepatic and renal impairment.

Because of the increased incidences of heart attack and stroke (observed in post-marketing studies), tegaserod has recently been withdrawn from many countries including India.

Chloride Channel Activator

Lubiprostone, a prostanoidic acid derivative, has recently been approved for treating women with constipation-dominant IBS. In men its usefulness has not yet been proved. It activates Cl⁻ channels in the small intestine to promote intestinal secretions and motility. It can be used on long-term basis but on stoppage the constipation reappears to pretreatment stage. Usual dose is 8 [tg BD orally. Side effects include nausea; contraindicated in pregnancy.

Miscellaneous Agents

- *Clonidine*, an α_2 -adrenergic receptor agonist, can also decrease visceral hyperalgesia and reduce distension-induced pain. It also enhances salt and water absorption from the intestine and hence prevents diarrhoea. It, therefore, can be used in diarrhoea-dominant IBS but its blood pressure lowering effects limit its use.

- **Buspirone**, an anxiolytic drug with a partial agonist action on brain 5-HT_{1A} receptors, can also reduce gastric and colonic sensitivity to distension and can be used as an adjuvant drug in the treatment of IBS.
- Other agents being used are CCK₁ receptor antagonists **loxiglumide** and **dex-loxiglumide** (see above) and **sumatriptan** a 5-HT₁ receptor agonist, but with little clinical success.
- **Methylnaltrexone** and **alvimopan** are two selective inhibitors of peripheral μ -receptors which may be used to antagonise opioid-induced constipation or to correct postoperative ileus in hospitalised patients; but their cardiovascular toxicity limits their use.

CHAPTER 29 Drugs for Constipation, Diarrhoea, Inflammatory Bowel Disease and Biliary and Pancreatic Disease

Constipation means delayed passage of faeces through the intestine with defaecation process remaining normal. Evacuation is often associated with straining and is usually incomplete.

Dyschezia means derangement of defaecation process which may result due to (1) pain arising from haemorrhoids or fissure, (2) presence of hard dehydrated faecal matter in the rectum or (3) sudden cessation of a habitual use of a purgative.

Normal defaecation clears only the descending colon, whereas purgatives empty the entire colon. Thus after the successful use of purgative, a few days are needed before the normal defaecation process restarts. During this phase, the patient feels psychologically constipated and takes the purgative again. A vicious cycle now builds up which is difficult to break. This leads to the development of "cathartic or purgative-habit". It is again a misbelief that the retention of faeces results in auto-intoxication due to absorption of toxins from the colon. It is not so; because it has been observed that the headache and the feeling of being sick, due to constipation, also result by artificial distention of sigmoid colon and rectum by plugging with cotton or by an inflated balloon. Hence, these symptoms are simply due to the physical presence of the faecal matter and not by its chemical toxicity.

Majority of cases suffer with only functional constipation which can be corrected by: (1) An increase in the roughage (fibrous content) in the daily diet; (2) An increase in daily fluid intake; (3) An increase in physical activity; (4) Not neglecting the nature's call; (5) Adjusting the daily routine; (6) Selecting alternative drugs which cause lesser constipation as side effect. Certain drugs like morphine, anticholinergics and aluminium or calcium group of antacids are known to cause constipation as side effect, and (7) Correcting the underlying pathology; as vitamin B₁₂ deficiency, hypothyroidism,

diabetes mellitus and Parkinson's disease etc., are some factors leading to constipation.

If all these non-therapeutic measures fail, laxative or purgatives can be used. Earlier many terms were being used as synonyms for the drugs used to relieve constipation. Their meaning and rank order of effectiveness is provided below:

Aperient (to get rid off) < *Laxative* (to loosen) < *Emollient* (to smooth and soften) < *Evacuant* (to empty) < *Purgative* (to clean) < *Cathartic* (to utterly clean).

Intensity of their action, however, depends on dose. A purgative in smaller doses can work as laxative and *vice versa*; while a purgative in higher doses can act as cathartic and *vice versa*. Hence such a classification has been dropped. Only two terms are now being used:

LAXATIVES, which result in elimination of soft semisolid stool and PURGATIVES, which provide more watery evacuation. However, these terms are used interchangeably and pharmacodynamic outcome effects are many times indistinguishable. In this text only the term purgative has been used.

PURGATIVES

Purgatives are used for complete colonic cleansing prior to

Purgatives are used: (1) to treat constipation, (2) to avoid undue straining at defaecation in cases having hernia, haemorrhoids or cardiovascular disease, (3) before or after any anorectal surgery or gastrointestinal endoscopic procedures, (4) for postoperative or post-MI bed-ridden patients, (5) to flush out worms after the use of an anthelmintic drug, and (6) to prepare the bowel before surgery or abdominal X-ray and may be needed for neurologically impaired patients.

1. Bulk-Forming Purgative

Examples: Wheat bran, Psyllium husk, Ispaghula husk, Semisynthetic cellulose such as carboxy-methyl cellulose and polycarbophils (synthetic fibers).

Site and Mode of Action: These are luminally active, hydrophilic, indigestible vegetable fibres. They stimulate peristalsis and defaecation reflexes by increasing faecal bulk due to their water absorbing and retaining capacity.

Dosage and Latency Period: Adequate amount of water must be taken with all bulk-forming laxatives. Choice of the agent is a matter of personal preference. Effect appears within 1 to 3 days. Bran powder or husk can also be sprinkled over stewed food.

Side Effects and Comments: These are not absorbed, and are quite safe. However, bacterial digestion of vegetable fibres within the colon may lead to bloating and flatus causing abdominal discomfort.

2. Osmotic Purgatives

Examples: (A) Saline purgatives: Magnesium sulfate, Magnesium hydroxide (milk of magnesia), Sodium sulfate and Sodium phosphate; (B) Polyethylene glycol (PEG)—Electrolyte osmotic purgative. *Osmotic purgatives lead to watery evacuation;* (C) Lactulose (10 g/15 ml), Sorbitol.

Site and Mode of Action: All of them act on small as well as large intestine.

A) *Saline purgatives* are soluble inorganic salts which increase the faecal bulk by retaining water by osmotic effect, thus increasing peristalsis indirectly. Magnesium salts also release cholecystokinin which further helps in increasing intestinal secretions and peristalsis.

B) *Polyethylene glycol (PEG)—Electrolyte osmotic purgative* contains a nonabsorbable polyethylene glycol (PEG) which is a sugar that retains water by virtue of its high osmotic nature. It is used in a form of a balanced isotonic solution prepared by adding sodium chloride, sodium sulfate, sodium bicarbonate and potassium-chloride. The isotonic solution of PEG is so designed that no electrolyte shift occurs across the intestinal wall. Therefore, the preparation is safe for all patients.

Dosage and Latency Period: Milk of magnesia, being tasteless, is the most commonly used saline purgative. Other salts have an unpleasant taste. 30 ml of its 8% w/w suspension is given in the morning because it is quite effective. Its effects come within 2-3 hrs. PEG—Electrolyte osmotic purgative is ingested orally. 4 liters of this solution should be ingested over 2-3 hours for complete colonic cleansing prior to GIT endoscopic procedures. For treatment of chronic constipation smaller doses of this solution can be used (300-500 ml daily in the morning or 17 g of the powder in 8 ounces of water per day). The latency period is 2-3 hrs.

Side Effects and Comments: The saline purgatives should be ingested with enough water, because being irritants these may induce vomiting. The hyper-osmolar agents may lead to intravascular fluid depletion and electrolyte disturbances. These should never be used on long-term basis and should be avoided in hypertensives and in cases of CHF. Magnesium salts should not be used for prolonged period in patients with renal insufficiency due to the risk of hypermagnesaemia, as about 20% of ingested magnesium is normally absorbed.

C) Lactulose (10 g/15 ml), Sorbitol.

Site and Mode of Action: It is also luminally active, nonabsorbable-indigestible disaccharide (sugar). It increases faecal bulk by hydrophilic action and also due to osmotic action.

Dosage and Latency Period: It is given in a dose of 10 g BD or TDS with plenty of water to produce 2 or 3 soft stools per day. Latency period is 1-3 days.

Side Effects and Comments: It is non-toxic and is also suitable for long-term use. Flatulence is common, cramps may occur in few. Some patients may feel nauseated due to its peculiar sweet taste.

Lactulose is also used for the treatment of hepatic encephalopathy. For this purpose a dose of 15 g TDS orally is needed. In hepatic encephalopathy there is a severe hepatocellular damage because of which the portal blood is directly shunted to systemic circulation.

Hence, several toxic metabolites from the colon (e.g., NH_3) get accumulated in the blood leading to CNS toxicity. Lactulose is degraded to lactic acid and converts NH_3 to ionised NH_4^+ salt which is then excreted.

3. Lubricant Purgative

Example: Liquid paraffin.

Site and Mode of Action: It is also a lumenally active agent. It is pharmacologically inert viscous liquid which contains mineral oil. It is a faecal lubricant and stool softener as it retards water absorption from the stool.

Dosage and Latency Period: It is given as 15-30 ml per day at bed time. Latency period is 1-3 days.

Side Effects and Comments: It is not palatable but can be given in emulsified form or with juices. Frequent use leads to the deficiency of fat-soluble vitamins (A, D, E & K) as they are carried away with stool in emulsified form. Forceful administration can lead to aspiration lipid pneumonia. It also delays the healing of enteric fistula. Though *used only occasionally* it is useful where straining at defaecation is to be avoided.

4. Surfactant Purgative

Example: Dioctyl sodium sulfosuccinate (Docusate sodium).

Site and Mode of Action: It is again a lumenally active agent and is an anionic surfactant which softens the stool by decreasing the surface tension of fluids in the bowel. It also acts as a wetting agent for the bowel, because by emulsifying the colonic contents it facilitates the mixing of water into fatty substances of the faeces.

Dosage and Latency Period: 100-400 mg orally per day (in divided doses). It is a mild laxative, specially indicated when straining at defaecation is to be avoided. Latency period is 1-3 days.

Side Effects and Comments: It is not absorbed and hence non-toxic. Being bitter in taste, it can cause nausea. Cramps and abdominal pain may occur. Hepatotoxicity may occur after prolonged use. It increases the absorption of liquid paraffin, hence should not be given together.

5. Irritant Purgatives

Examples: (A) Anthraquinone group: Senna, Cascara and Aloe; (B) Organic irritants: Phenolphthalein, Bisacodyl (and its suppository); Sodium picosulfate; and (C) Oils: Castor oil. *Irritant purgatives provide soft semifluid stools.*

Site and Mode of Action: All of them stimulate peristalsis by irritant action on intestinal mucosa. They also stimulate colonic electrolyte and fluid secretion by altering the absorptive and secretory activity of the mucosa cells. *Aloe, senna* and *cascara* occur naturally in plants. *Senna* is most commonly used. These plant purgatives contain anthraquinone glycosides. On reaching the colon, the bacteria degrade them to the active principle—"anthrol"—which either acts locally or is absorbed into circulation. After being excreted through bile it then stimulates small intestine.

The primary site of action of *organic irritants* is in the colon. *Bisacodyl* is metabolised in the intestine into an active deacetylated metabolite. In the colon *sodium picosulfate* is also converted to an active metabolite which stimulates peristalsis and promotes water and electrolyte accumulation. *Castor oil* itself is non-irritant. It is hydrolysed in intestine by pancreatic lipase to ricinolic acid which increases the intestinal motility.

Dosage and Latency Period: Calculated on the basis of *Senna glycosides*: Sennoside A and B; these are given in a dose of 12-25 mg (approx) at bed time. Effect comes within 6-8 hours. *Phenolphthalein* (though seldom used now) is given in a dose of 60-130 mg at bed time. The effect appears within 6-8 hrs. *Bisacodyl* is given in a dose of 5-10 mg at bed-time. The effect appears within 8-10 hrs. Suppositories (10 mg) are also available. *Sodium picosulfate* is administered in a dose of 5-10 mg at bed time. It is usually effective within 6-8 hrs. *Castor oil* (because of unpalatability and side effects) is seldom used these days. Usual dose is 15-25 ml in the morning as the effect appears within 3 hrs.

Side Effects and Comments: *Senna glycosides* are secreted through milk, hence should be avoided in lactating mothers. These glycosides turn urine colour to yellowish-brown (acidic urine)

or to red (alkaline urine). Chronic use leads to a characteristic brown pigmentation of the colon known as "melanosis coli". It is contraindicated in pregnancy to avoid pelvic congestion. All anthraquinones can produce abdominal cramps and nausea. About 15-20% of *phenolphthalein* undergoes enterohepatic circulation and hence exhibits prolonged action. It turns urine reddish-pink, if alkaline. Skin rash may occur (but rarely). Its use has drastically declined because of the reports about its cardiac toxicity and carcinogenicity.

Bisacodyl, is however, quite safe, except for occasional abdominal cramps and skin rashes. Prolonged use or overdosage of *sodium picosulfate* can cause colonic atony and hypokalaemia. *Castor oil* is no longer a favoured purgative because of its unpalatability, frequent cramping, after-constipation, and risk for damaging intestinal mucosa. It is contraindicated in pregnancy (to avoid pelvic congestion). However, its purgative action is self limiting because irritant action of ricinolic acid increases peristalsis, which sweeps away the remaining castor oil.

For other drugs, to treat constipation, refer irritable bowel syndrome (Ch. 28).

ANTIDIARRHOEAL AGENTS

Diarrhoea is an abnormal increase in the Frequency and the liquidity of stools. Increased motility of GIT and the decreased ability of intestine to absorb water from the stool are the major factors in the causation of diarrhoea. Treatment of specific-infective diarrhoeas needs proper diagnosis and appropriate drug treatment by selecting proper antibiotic or an antiprotozoal drug or a combination of both. Similarly, diarrhoea due to underlying pathology or endocrinal disorders can be treated by correcting the underlying cause. However; for the symptomatic relief of non-specific diarrhoeas, the following category of drugs can be used:

Antimotility and Antisecretory Agents

1. Opioid Agonists

The drugs which fall in this category are *loperamide*, *diphenoxylate*, *difenoxin* (an active metabolite of diphenoxylate) and *racecadotril*. These drugs act by

stimulating peripheral 11 (μ) as well as 6 (δ) receptors present on small and large intestine. Activation of 11 receptor decreases motility; while activation of 8 receptors decreases intestinal secretions. Although all opioids such as morphine or codeine have antidiarrhoeal effects, their CNS effects and dependence liability limit their usefulness. *Loperamide* is an OTC drug among opioid agonists that does not cross BBB and has neither analgesic effects nor any addiction liability. As an antidiarrhoeal agent it is 40 times more potent than morphine. The usual adult dose is 4 mg followed by 2 mg after each loose motion to a maximum of 16 mg/day (onset of action: 1-2 hrs; duration of effect: 6-12 hrs). However, for chronic diarrhoeas it is commonly given as 2-4 mg TDS. *Diphenoxylate* or its active metabolite *difenoxin* are other opioid agonists that have no analgesic properties. However, higher doses have CNS depressant effects and exhibit dependence liability after prolonged use. As an antidiarrhoeal agent it is more potent than morphine but less potent than loperamide. The most popular formulation (LOMOTIL) contains *diphenoxylate* (2.5 mg) with small doses of *atropine* (0.025 mg) to discourage abuse potential. Atropine, besides providing antispasmodic effects, prevents the possible abuse of diphenoxylate because undesirable effects of atropine would appear prior to the pleasurable effects of the opioid, if the dose is increased for abuse. Usual dose is 2 tabs TDS or QID.

These drugs have been shown to be effective against traveler's diarrhoea or to prevent non-specific diarrhoea; but replacement of fluids through ORS (see below) is still the mainstay for such therapy.

In the recommended doses, these drugs are well tolerated, except for some milder side effects like abdominal discomfort and dry mouth. These drugs should not be used in patients with colitis in order to avoid development of megacolon. These medications should be avoided in patients suffering from acute bacterial diarrhoeas associated with high fever or blood in stool because of the potential of these drugs to decrease the clearance of the pathogens and to enhance the subsequent systemic

invasion of these organisms. These should not be used in children below 2 years of age (danger of paralytic ileus).

Racecadotril is a new antidiarrhoeal drug that belongs to this group. It is the enkephalinase inhibitor that increases local concentration of enkephalins in intestinal mucosa which then stimulate μ and δ opioid receptors (like loperamide) to produce antidiarrhoeal effects. However, its antisecretory effects are more pronounced compared to its antimotility effects. Usual adult dose is 100-300 mg TDS. Side effects are mild and include nausea, constipation and headache. It is secreted through breast milk and hence should be avoided in lactating mothers. No significant drug interactions have been reported.

2. Anticholinergics

Anticholinergic drugs like *hyoscyamine* and *dicyclomine* decrease bowel motility which results in an increase of fluid absorption, back from the intestinal tract, and a decrease in abdominal cramps. However, these drugs are not used as a sole antidiarrhoeal drug but are used in combination with adsorbents or opiates. Adverse effects include the usual anticholinergic effects.

3. α_2 -Adrenergic Receptor Agonists

Clonidine (0.1 mg BD, oral) facilitates absorption, inhibits secretion of fluids and electrolytes as well as increases the intestinal transit time. Clonidine and substitutes may have a special role in the treatment of diabetic diarrhoea and in diarrhoea caused by opiate withdrawal. However, its blood pressure lowering effects are the major limiting factors for its use as a routine antidiarrhoeal agent.

4. Octreotide

It is a synthetic octapeptide with actions similar to somatostatin (Ch. 41). It has a longer half life (1.5-2 hr) compared to somatostatin (3 min). It is even more potent than somatostatin in inhibiting the secretion of growth hormone, glucagon, insulin and VIP. However, its antidiarrhoeal effects involve the inhibition of the release of 5-HT, gastrin, secretin, CCK, motilin and pancreatic polypeptide. It reduces

GIT motility, intestinal fluid and electrolyte secretion, pancreatic secretion and gall bladder contractions. It is, therefore, mainly used to treat secretory diarrhoeas associated with carcinoid tumours and VIP secreting tumours as well as to treat acromegaly and to prevent variceal bleeding (as it decreases hepatic blood flow). It may be given subcutaneously in a dose of 10014 BD or TDS. In low doses (50 1.1.g S.C.) it rather stimulates GIT motility. Side effects depend on duration of treatment. A short-term therapy leads to slight nausea, abdominal discomfort and pain at the site of injection. Long-term therapy can lead to gall stone formation and hypothyroidism. Impaired pancreatic secretion may cause steatorrhoea which can lead to fat-soluble vitamin deficiency.

The new analogs of octreotide are lanreotide, seglitide and vapreotide. Out of these lanreotide has longer duration of action of about 4 weeks

Adsorbent Drugs

Kaolin is a hydrated magnesium-aluminium silicate while *pectin* is a sort of indigestible purified carbohydrate obtained from apple. Both the agents adsorb bacteria, enterotoxins and fluid to increase the consistency of faecal matter. Pectin being demulcent, coats the inflamed GIT mucosa also. *Kaolin pectin combination* had been a popular formulation before, but seldom used now.

Bismuth subsalicylate reduces stool frequency and liquidity in acute diarrhoea due to inhibition of PG synthesis and secretion by its salicylate counterpart. Bismuth has some antimicrobial effects, binds to enterotoxins and also provides protective coating over inflamed gastric mucosa. It is given in a dose of 524 mg (or 30-60 ml) every six hours daily to control traveler's diarrhoea. For acute diarrhoea doses may be increased up to 8 doses per 24 hrs. It is now rarely used because the doses required for relief are large and need to be administered frequently. Being not absorbed, adsorbents have minimal side effects except constipation. Bismuth subsalicylate causes blackening of stool (mistaken for melaena) and darkening of tongue because of a reaction between bismuth and the sulfide (produced by bacteria) to form a black bismuth sulfide.

No adsorbent drug (discussed above) should be taken within 2 hrs of other medication, because it may decrease the absorption of other orally administered drugs.

Miscellaneous Agents

Lactobacillus sporogens are intended to replace the normal bacterial flora that is lost during acute diarrhoea or due to the use of antibiotics. These are also used as an adjuvant therapy for aphthous stomatitis and diarrhoea.

Lactase is indicated for individuals who have insufficient amount of lactase in the small intestine. Lactase is an enzyme responsible for digesting lactose, a common disaccharide present in the dairy products. In absence of lactase, lactose draws water into the GI tract and causes diarrhoea. The dose is 1-2 capsules of lactase taken with milk.

Non-Pharmacological Measures Fluid and Electrolyte Replacement (Oral Rehydration Therapy; ORT)

During diarrhoea, a glucose-coupled sodium transport continues in the intestine which causes water and electrolyte losses through stools. Hence, glucose-electrolyte solutions are simple, effective and cheaper oral therapy to treat a vast majority of watery diarrhoea. However, if fluid loss is severe and/or severe vomiting persists, there may be a need for I.V. fluids before oral maintenance rehydration therapy can be pursued. Oral rehydration solution (ORS) replaces the fluid or electrolytes what the body has lost due to diarrhoea. The *glucose-based* ORS can easily be made at home as per WHO standard formula:

Sodium Chloride	3.5 g
Potassium Chloride	1.5 g
Sodium Citrate	2.9 g
Glucose	20.0 g
Water	1 L
Total osmolarity 311 mmol/L	

The higher sodium content of WHO formulation is based on approximate sodium loss in adult diarrhoea. However, low-sodium glucose-based formulations may be preferred in infants and children whose faecal

losses of sodium are less. The WHO has recommended the replacement of standard 311 mmol/L formula by the new 245 mmol/L formula.

Sodium Chloride	2.6 g
Potassium Chloride	1.5 g
Sodium Citrate	2.9 g
Glucose	13.5 g
Water	1L
Total osmolarity 245 mmol/L	

For mild to moderate diarrhoea in adults, approximately 2-3 liters of any one of the ORS cited above should be consumed within first 4 hrs. Thereafter, simply the ongoing losses are to be replaced.

Carbonated soft drinks, tea, coffee, powdered drinks and hypertonic juices should be avoided in diarrhoea because these make diarrhoea worse and do not contain the electrolytes needed.

The *cereal-based* ORS has the advantage of controlling diarrhoea much more effectively than the *glucose-based* ORS. This may be because undigested starch is fermented in the colon to short chain fatty acids which stimulate sodium and water absorption back from the colon. Further, rice powder has 7% protein which on hydrolysis yields amino acids that too stimulate colonic salt and water absorption. The commonly used *rice-based* ORS formula is as under:

Precooked rice flour	10.15 g (extruded)
Sodium Chloride	0.94 g
Sodium Citrate	0.20 g
Potassium Citrate	0.44 g
Water	200 ml

TREATMENT OF INFLAMMATORY BOWEL DISEASE

Ulcerative colitis and Crohn's disease are the two important diseases among the inflammatory bowel diseases. The pathogenesis of these diseases involves immune mechanism and an imbalance between proinflammatory and anti-inflammatory cytokines. The main drugs used in the treatment of ulcerative colitis and Crohn's disease are the aminosalicylates and corticosteroids, though recent

introduction of certain immunosuppressants and anti-TNF α drugs constitute some novel therapies for the treatment of inflammatory disease. Antidiarrhoeals should be avoided in active and severe ulcerative colitis as they can lead to dilatation of colon and its perforation.

Ulcerative Colitis

Aminosalicylates

Sulfasalazine, *olsalazine* and *balsalazine* contain a 5-aminosalicylic acid (5-ASA) moiety bound by an azo (N=N) bond to an inert moiety or by another 5-ASA molecule. In *sulfasalazine*, 5-ASA is bound to sulfapyridine; in *balsalazine* 5-ASA is bound to an inert carrier 4-aminobenzoyl-3-alanine, while in *olsalazine* two 5-ASA molecules are joined to each other. Azo compounds, in general, are least absorbed in stomach and small intestine. When they reach terminal ileum and colon, the colonic bacteria split the azo compound by an azoreductase enzyme that releases 5-ASA in higher concentration at the desired site of action. Sulfapyridine released from *sulfasalazine* (along with 5-ASA) is absorbed, acetylated in liver and excreted in urine. By contrast, the breakdown product of *balsalazine*, after azoreduction is not absorbed but excreted as such in faeces. These components of the drug molecule merely serve as an inert carrier for 5-ASA and have no therapeutic action in colitis. 5-ASA (the active moiety) has only topical anti-inflammatory action (not systemic). The generic name of 5-ASA is "*mesalamine*".

Patients intolerant to *sulfasalazine* or *balsalazine* usually tolerate *olsalazine* which contains two 5-ASA molecules joined together by an azo bond. Most of the adverse effects of *sulfasalazine* are attributable to its associated sulfapyridine moiety. Recently, *Mesalamine* with pH-sensitive coating has been introduced which releases 5-ASA directly in the terminal ileum and the colon. It is claimed to be a more efficacious formulation with lesser side effects.

5-ASA inhibit the synthesis of prostaglandins by inhibiting cyclo-oxygenase, like salicylates, as well as inhibit the production of cytokinins. 5-ASA also inhibits the activity of nuclear factor-kB which is an important transcription factor for

pro-inflammatory cytokines. It also suppresses the generation of superoxide free radicals.

Sulfasalazine group of drugs induce as well as maintain the remissions in patients of ulcerative colitis. 5-ASA suppository or enema is useful in patients with ulcerative colitis confined to rectum or distal colon but if ulcerative colitis extends up to proximal colon, systemic use of these drugs is more beneficial. Oral dose of *sulfasalazine* is 1 g 6 hrly until remission occurs; thereafter 1 g BD for maintenance. *Sulfasalazine* group of drugs are also useful as disease modifying antirheumatoid drugs (DMARD, see Ch. 26). *Balsalazine* is given as 2.25 g TDS orally followed by 1.5 g BD for maintenance. pH-sensitive *mesalamine* is given as 800 mg orally TDS and then 400 mg TDS for maintenance.

Their *adverse effects* are due largely to the presence of carrier molecule and include headache, anorexia, nausea-vomiting, allergic reactions like skin rash, fever and lymphadenitis. *Sulfasalazine* in high doses or on prolonged use can lead to reversible oligospermia and male infertility. *Sulfasalazine* impairs folate absorption. Dietary supplements of folic acid

are usually required to compensate the needs. Other formulations of ASA are better tolerated than *sulfasalazine*. However, *olsalazine* may stimulate secretory diarrhoea which can create diagnostic confusion in patients with inflammatory bowel disease.

Immunosuppressants

1. Glucocorticoids

Prednisone and *prednisolone* have been the mainstay of the treatment for acute/severe exacerbations of inflammatory bowel disease. These have an intermediate duration of action allowing once daily dosing. When ulcerative colitis is restricted to the left hemicolon, exacerbations that do not respond to 5-ASA alone can normally be controlled by steroid retention enema. The foam-based formulations appear

to coat the colonic mucosa more effectively than the aqueous formulations. Moderately severe attacks of ulcerative colitis should be treated with systemic glucocorticoid, administered orally. Oral *prednisone* in a starting dose of 40 mg once a day or *prednisolone* 60 mg once a day are considered as standard dose regimen. Higher doses have not been

more beneficial. The anti-inflammatory response appears within 2 weeks. Once remission has been attained, the doses can be tapered down over a period of 6-8 weeks. If there is no improvement, immunosuppressants and/or infliximab may be used to induce remission (see below). 5-ASA may then be used for the maintenance therapy, as corticosteroids are not useful for maintenance. The mechanism of action and the side effects of glucocorticoids are detailed in Chapter 42.

2. Cyclosporine

Cyclosporine may induce remissions in case of severe ulcerative colitis unresponsive to corticosteroids. It causes pronounced suppression of proinflammatory transcription factors. It is given in a dose of 2-4 mg/kg/day I.V., until remission is attained. Later for maintenance therapy, *azathioprine* is often substituted as cyclosporine is not effective for maintenance therapy. Renal functions should be closely monitored while using cyclosporine as it is nephrotoxic (Ch. 69).

3. Azathioprine and 6-Mercaptopurine

These are purine antimetabolites that have immunosuppressive properties (Ch. 69). Azathioprine is a prodrug yielding 6-mercaptopurine (which is azathioprine without a side chain). Both these drugs can be used interchangeably. Azathioprine is given in a dose of 2.5 mg/kg/day while 6-mercaptopurine is given in a dose of 1.5 mg/kg/day. Both get converted to active metabolites having longer half-life. As a result the therapeutic effects of azathioprine are delayed by about 6-8 weeks. Hence, it is not effective for inducing remission in patients of ulcerative colitis. These drugs are primarily used for maintenance of remission for ulcerative colitis. Azathioprine or 6-mercaptopurine may allow dose reductions or elimination of steroids in patients of ulcerative colitis.

The toxicities of these drugs are dose related and include nausea, vomiting, bone marrow depression and hepatotoxicity. Hence, liver function tests and blood counts should be monitored

intermittently. Pancreatitis, which probably is a hypersensitivity reaction, can occur in about 5% of the cases. Risk of teratogenicity appears to be negligible. 6-Mercaptopurine is better tolerated than azathioprine.

Allopurinol markedly inhibits the metabolism of these purine analogues. Hence the dose of 6-mercaptopurine or azathioprine should be reduced appropriately in patients receiving allopurinol.

Crohn's Disease

Ulcerative colitis and Crohn's disease have several overlapping features and so do the drugs used for their treatment which also share many properties that are beneficial in both the disease conditions. Ulcerative colitis is confined to the colon and the inflammatory processes, which are usually superficial and involve the distal portions, can extend for a variable length proximally. Crohn's disease on the contrary can affect both the small as well as large intestine and, although less commonly, any other segment of GIT which can be complicated further by intestinal strictures, fistula and intra-abdominal abscess.

Treatment depends on the site of disease. Management of colonic Crohn's disease is very similar to that of ulcerative colitis treated with 5-ASA and corticosteroids. Sulfasalazine group of drugs are ineffective in small bowel Crohn's disease because these drugs liberate 5-ASA in the colon. In more severe disease, corticosteroids are needed to induce remission but are of little value in maintaining remission. *Budesonide*, a potent topically active corticosteroid, can also be administered either orally or as enema but with a little success as even a delayed release formulation has a very poor bioavailability. However, enteric-coated budesonide has been recently introduced to treat ileocaecal Crohn's disease. Dose: 9 mg/day for 12 weeks. There is no supportive evidence to prove that cyclosporine is effective in Crohn's disease. Other drugs which are beneficial in the management of Crohn's disease are as under:

1. Anti-TNF α Drugs

infliximab, Adalimumab and Certolizumab

Increased levels of TNF α are found in faecal samples of the patients of Crohn's disease. *Infliximab* is a

chimeric (25% mouse + 75% human) monoclonal antibody that cross-links with soluble as well as membrane bound TNF α receptors and inhibits T-cells and macrophage functions. Consequently, the release of other proinflammatory cytokines (IL-1, 6 and 8; collagenase and metalloproteinases) is prevented. It is administered in a dose of 5-10 mg/kg by I.V. infusion at 0, 2 and 6 week interval. A single dose of infliximab induces remission in approximately 40% of patients with Crohn's disease resistant to conventional therapies. An additional dose after 8 weeks appears to produce long-lasting remission. *Adalimumab* is a recombinant 100% human anti-TNF α monoclonal antibody. Its mode of action is similar to infliximab. It is given subcutaneously (160 mg, 80 mg and 40 mg at 0, 2 and 4 weeks, respectively) and has a longer plasma half-life. It has lesser immunogenicity and side effects compared to these drugs. For adverse effects profile of these drugs refer Chapter 26. There is no substantial proof about the efficacy of infliximab in ulcerative colitis. Like adalimumab, *certolizumab* also is a recombinant monoclonal (95% human) antibody with similar mode of action. It is given as 400 mg (S.C.) at 0, 2 and 4 weeks interval. Certolizumab, as it lacks Fc portion in its structure, does not produce antibody-mediated apoptosis and complement-mediated cytotoxicity of cells expressing membrane-bound TNF α .

2. Methotrexate

Methotrexate is useful in controlling relapse of Crohn's disease unresponsive to corticosteroid or azathioprine. It is a cytotoxic agent (Ch. 67) with pronounced immunosuppressive (Ch. 69) and anti-inflammatory properties (Ch. 26). 15-25 mg I.M. or S.C. injection of methotrexate every week appears to be effective in steroid-dependent Crohn's disease but not in ulcerative colitis. However, its adverse effects on long-term use, including bone marrow suppression, pulmonary and hepatic fibrosis limit its use in Crohn's disease.

3. Antibiotics

In contrast to ulcerative colitis about 50% of patients with colonic Crohn's disease respond to *metronidazole* and/or *ciprofloxacin*. However, adverse effects as a consequence of long-term therapy (Ch. 65) limit their usefulness. Certain

bacterial strains (e.g., *Bacteroides*) are pro-, while some (e.g., *Lactobacillus*) are anti-inflammatory. Hence, probiotics have also been used as adjuvants in the management of Crohn's disease.

4. Anti-Integrin Monoclonal Antibody

Integrin and selectins are two different classes of adhesion molecules found on the surface of leukocytes and on vascular endothelium, respectively. During inflammatory process circulatory leukocytes get adhered to vascular endothelium and subsequently penetrate through the vessel wall into other tissues. The α -4 subunit of integrins is involved in binding of leukocytes to the vascular adhesion molecules. *Natalizumab* is a humanised monoclonal antibody against α -4 subunit of integrin and their subsequent migration into surrounding tissue. Though withdrawn in 2005, due to controversial reports about its association with progressive multifocal leukoencephalopathy (PML), it was reintroduced later for restricted use in patients of Crohn's disease who did not respond to other therapies. Dose: 300 mg every 4 weeks by I.V. infusion. Concomitant use of other immunosuppressant drugs is contraindicated (reactivation of latent human polyomavirus leading to PML).

29

DRUGS USED IN PANCREATIC INSUFFICIENCY

Pancreatic enzymes supplements, which normally contain a mixture of amylase, lipase and proteases, are the mainstay of the treatment of the pancreatic enzyme insufficiency which is most commonly caused by cystic fibrosis, chronic pancreatitis or pancreatic resection. Exocrine pancreatic enzyme deficiency leads to fat and protein indigestion which in turn causes steatorrhoea, azotorrhoea, vitamin deficiency and weight loss.

Most commonly used preparation is *pancrelipase* which has a more powerful lipolytic and proteolytic activity compared to pancreatin. Since pancrelipase is acid-labile, its enteric coated formulation is used. The non-enteric formulation should be used along with H₂-blockers or PPIs (to reduce chances of its gastric acid destruction). It is given in a dose that provides 30,000 Units of lipase activity post-meal; addition of H₂ blocker or PPI may

improve response. The enteric-coated tablet should be swallowed and not chewed, not only to prevent gastric acid destruction of pancrelipase, but to avoid the risk of producing oropharyngeal mucositis caused by the enzyme itself. Higher doses should not be used in patients with cystic fibrosis as they may cause ileocaecal and large bowel strictures.

Pancreatin is another preparation commonly used in developing countries. It is obtained from pig pancreas and contains amylase, trypsin and lipase. It is much less potent than pancrelipase. Its properties and side effects are similar to pancrelipase.

Miscellaneous Enzymes

Papain is obtained from raw papaya while *pepsin* powder is prepared from gastric mucosa of pigs, cattle or sheep. Both have proteolytic activity which helps in degradation of proteins into peptides of low molecular weight. Pepsin maintains its activity in acidic medium (pH 1-5). It is used along with HCl or glutamic acid as an adjunct in the treatment of gastric hypochlorhydria or to treat digestive enzyme deficiency. *Diastase* and *takadiastase* are amylolytic enzymes (amylase) obtained from fungus *Aspergillus oryzae*. It hydrolyses polysaccharides to sugars.

These enzymes are sometimes also used in pancreatic insufficiency but efficacy is doubtful.

DRUGS FOR CHOLESTEROL GALLSTONES

Cholesterol (CH) remains dissolved in bile with the help of bile salts. A high CH:bile salt ratio favours

crystallisation of CH in bile leading to gallstone formation. *Ursodeoxycholic acid (ursodiol)* is the only available agent for dissolution of gallstone. It is a minor constituent of human bile (but major bile acid in the bear, hence the prefix *urso*). It is effective only in a functional gall bladder. If the bile is not entering the gall bladder, it would not be able to solubilise the stones.

Ursodiol (ursodeoxycholic acid) promotes dissolution of gallstones because: (1) It inhibits absorption of cholesterol from intestines, (2) It reduces CH secretion in the bile, shortly after the initiation of the drug therapy, (3) It lowers saturation index of bile so that it is no longer lithogenic and (4) It promotes solubilisation of gallstone by liquid crystal formation.

Ursodiol in a dose of 7-10 mg/kg/day usually dissolves small non-calcified CH stones (<10 mm dia) in gall bladder in 50% of patients but its use beyond 2 years is not justified. It is also effective for the prevention of gallstones in obese patients undergoing rapid weight loss therapy. Ursodiol 13-15 mg/kg/day (in 4 divided doses after some food) is useful in patients with early primary biliary cirrhosis (reduces liver function abnormalities and improves liver histology). Ursodiol may produce diarrhoea. About 30% of cases may have stone recurrence.

Drug Dependence and Drug Abuse

DEFINITIONS AND TERMINOLOGY

The professionals in the field of drug abuse and drug addiction have so much diverse background, that adopting a common definition for terms such as drug abuse, misuse, habituation, addiction and dependence becomes very difficult if not impossible. *Polydrug abuse* further complicates the conclusions drawn from epidemiology and clinical studies, because users often attempt to modify the selected drug effects by coabusing drugs with opposite pharmacological effects.

Indiscriminate use of any drug, other than a CNS stimulant or depressant drug, is called its MISUSE, e.g., misuse of laxatives, purgatives or of antibiotics etc., while the misuse of any CNS stimulant or a depressant drug is called its ABUSE. The term abuse also, unfortunately, has different meanings for different people. It also means any use of a drug for nonmedical purposes, not only for altering consciousness or mood but also for body building. Till 1964, DEPENDENCE was considered as biological phenomenon often associated with 'drug abuse', but its precise scientific meaning was not clear. For example, ifscail 'cone is occasionally taking alprazolam, as self-medication, to relieve anxiety, then it may be a drug abuse without dependence, whereas if a diabetic person is taking insulin every day, he is dependent on insulin without any drug abuse or misuse. Similarly there could be misuse of laxatives/purgatives leading to dependence. The problem was that the term dependence was being used indiscriminately with no demarcations between its literal and scientific meaning. These discrepancies were resolved later (see below).

Almost all abused substances or drugs produce an effect on the brain that is perceived as desirable and will initiate a "**drug seeking behaviour**". The properties of the drug that are responsible for drug seeking behaviour are often referred to as "**reinforcing properties**". These drugs produce

effects that are so desirable that the user is compelled to get more of the drug. The primary reinforcing property of the drug is the "*positive affective state*" called EUPHORIA that it produces. This term indicates anything from pleasantness or a sense of well-being to an excitement resembling orgasmic pleasure. Euphoria is considered to be a "*positive reinforcing*" property of the drug that an individual would desire or would like to seek. In addition, the drug can also function as "*negative reinforcer*" in that it offers relief from a negative affective state, e.g., DYSPHORIA.

Chronic exposure to reinforcing drugs can lead

to *drug addiction* (again an imprecise term, see following text) which is characterised by an increase in drug seeking behaviour called CRAVING. The evaluation of drugs for their craving or reinforcing property forms the basis for assessing their ABUSE POTENTIAL. The abuse potential of a drug can be qualitatively assessed (strong, moderate or mild) on a rodent model by implanting a cannula in the reward area (mesolimbic area) of the brain. In an animal cage,

a bar is placed in such a way that pressing the bar automatically delivers a fixed dose of the trial drug to the animal. **If** the animal eventually and repeatedly presses the bar or tries to overcome the intentionally placed obstacles, to press the bar, it can be concluded

that the drug has a positive reinforcing behaviour, i.e., abuse potential.

The older terms, HABITUATION and ADDICTION are not scientifically defined but surprisingly have not been completely abolished yet from the textbooks. The term **habituation** can be used if **(a)** *the detrimental effects of the abused drug* are restricted to the person himself and *not to the society*, **(b)** *there is no intense craving for seeking the drug*, **(c)** *there is no development of tolerance* and **(d)** *there are no distressful*

withdrawal effects, i.e., there is *no necessity*
or

physical need to continue with the drug for the fear

of abstinence syndrome. Examples include taking tea or coffee. *Addiction* involved the recurrent abuse of a drug where the individual becomes so obsessed to procure and use the drug that it becomes his primary aim, which in turn disrupts his abilities to adjust the family, the society or at his place of work. *Addiction* included the following features: (a) *the detrimental effects of the drug* not only *harm* the individual but *the society as well*, (b) there is always *an intense craving to procure the drug by any means*, (c) there is *development of tolerance* and hence a need to increase the dose to get the same rewarding experience, and (d) *there are life-threatening or alarming withdrawal effects* after cessation of the drug and hence there is a *physical need to continue with the use of the drug for the fear of abstinence syndrome*. However, as it may be noticed, the features

of habituation and addiction might also overlap and the terminology may become misleading. Consider a person who was a regular user of marijuana and *only once he had such intense craving* (due to environmental settings) that he committed a crime to procure this drug. On the contrary, consider a medical professional but an opioid (pethidine) addict who regularly had an intense craving for the drug but never committed any crime as his operation theatre staff and doctor friends were regularly obliging him for his requirements. In first case the craving was caught while in second case it remained unnoticed. Hence in 1974-75, WHO deleted all such terms (like habituation and addiction) and introduced another term called DRUG DEPENDENCE which meant: a) a state arising from *repeated, periodic or continuous use of a drug*, (b) a state which includes *all types of detrimental effects*, whether to himself, to the family, to the society or to the career, (c) a state that includes *all grades of craving* to procure the drug, and (d) a state which includes *all types of psychological and physical needs* to continue with the use of the drug for the *fear of getting distressful withdrawal effects*. Thus WHO provided a wider canvas for presenting the picture by using the terms such as "all grades of craving", "all types of psychological or physical needs" and "all sorts of detrimental effects" etc.

Substance dependence requires at least 3 (even more) of the following symptoms to be present for diagnosis: (1) development of tolerance, (2) distressful abstinence syndrome after cessation of the drug, (3) persistent desire to use the drug (craving) or failure to cut down its use, (4) substance use in larger amounts than intended, (5) withdrawal from social, occupational or recreational activities, (6) considerable time spent for obtaining the drug which becomes his life-style, e.g., visiting multiple doctors, quacks or his contacts in illicit drug trade, and (7) continued use despite health, social, economic, family and legal problems resulting from substance use.

The DSM-IV TR criteria for *substance abuse* requires at least one (or more) of the following symptoms to be present for diagnosis: (1) recurrent substance use resulting in a failure to fulfill his/her major obligations at work, school or home (e.g., repeated absence or poor performance at work; expulsion from school), (2) recurrent substance use even in situations where it should not be used, e.g., during driving; operating a machine or operating upon the patient, (3) recurrent substance-use despite punitive action, e.g., punishment for disorderly conduct, and (4) recurrent substance-use despite having interpersonal and family problems, e.g., arguments or physical fight with spouse about the

consequences of abuse. The "substance abuse" discards all other terms like misuse, abuse or habituation. Substance abuse does not apply on taking tea, coffee or smoking 10 cigarettes a day without inhalation.

TOLERANCE, DEPENDENCE, REBOUND, RELAPSE, WITHDRAWAL AND DETOXIFICATION

Tolerance develops if, after repeated administration, a given dose of a drug produces a decreased effect than expected, or conversely, when larger doses are needed to obtain the effects obtained with previous dose. It may be classified as *pharmacokinetic* (as with barbiturates) or *pharmacodynamic* (as with opioids) or as *reverse tolerance* (*sensitisation*, as with cocaine). For details refer Chapter 7. Related to this is **cross tolerance** where, once tolerance to primary drug develops, the individual also exhibits cross tolerance to related classes of drugs. For instance, individuals tolerant to morphine are also tolerant to other opioids and chronic alcoholics are also tolerant to benzodiazepines or even general anaesthetics. **Dependence** is a physiological state of neuroadaptation (see below) resulting from repeated administration of the drug, necessitating its continued use to prevent the appearance of distressing withdrawal (abstinence) syndrome which is manifested as opposite to the pharmacological effects of the drug. **Cross dependence** means the ability of a drug to suppress the manifestations of withdrawal (or physical dependence, see below) produced by another drug. **Withdrawal** or **abstinence syndrome** is a term used for the adverse (sometimes life threatening) psychologic and physiologic reactions to an abrupt discontinuation of a dependence-producing drug.

The **substance dependence** may be of two types: PSYCHOLOGICAL (PSYCHIC) DEPENDENCE which is characterised by (a) moderate compulsive drug seeking behaviour (craving) for personal satisfaction, e.g., cigarette smoking, (b) tolerance may or may not be present and if present it is usually either of pharmacokinetic type or tachyphylaxis but rarely pharmacodynamic (cellular adaptive), and (c) withdrawal effects are

less frequent and mild which can be tolerated as these are never life threatening. PHYSICAL DEPENDENCE is characterised by (a) intense craving for the drug, e.g., alcohol, opioid use, (b) tolerance is invariably present (mainly pharmacodynamic type), and (c) withdrawal effects are severe and distressing manifested by symptoms that are frequently opposite to those sought by the abuser. *Psychological (psychic) dependence* appears prior to *physical (physiological) dependence* but inevitably does not lead to it. Agents having physical dependence do possess psychic dependence as well, but reverse may not be true. Physical dependence is closely associated with the phenomenon of tolerance but the reverse may not be true.

Rebound means an exaggerated manifestation of the original disease symptoms experienced immediately after discontinuation of the drug providing the clinical benefits, e.g., *rebound hypertension* occurring after sudden discontinuation of clonidine or β -blockers. Rebound phenomenon should not be confused with withdrawal syndrome as there is no craving or dysphoria after the cessation of the drug. **Relapse** refers to re-occurrence of the same disease symptoms, from which the patient suffered, after discontinuation of the treating drug, e.g., if a diabetic person suddenly stops taking insulin, there would be *relapse* of diabetes (not rebound or withdrawal syndrome). **Detoxification** (in drug abuse terminology) means slow tapering of the drug that has caused dependence and would cause withdrawal if stopped suddenly. It can be accomplished either by slowly withdrawing the dependence producing drug or by substituting the cross-dependent drug (see below) so that the neuroadaptive mechanisms can slowly become normal without causing withdrawal symptoms. Tapering of the doses of β -blockers or clonidine, to prevent rebound hypertension, is not called detoxification but *tapered-dose discontinuation*.

WHY PEOPLE GO FOR DRUGS

The "drive(s)" that induce a person to resort to drugs are outlined below along with neuropharmacological aspects of drug reinforcement and reward

(Fig. 38.1). The "drives" include: (a) to get relief from tension and anxiety, (b) to satisfy their curiosity about the "kicks and pleasure" the drugs provide, (c) to show their identity by exhibiting hostility towards the society, (d) a notion of being accepted by the High modern society, and also (e) a notion that drugs provide new ideas for creativity.

The "drive(s)" cited above bring a normal person to a "drive state" and to cope with this situation, he has two options: (a) either to fight with the situation and circumstances with full determination or to become an escapist or to try other resorts to allay the anxiety or (b) to obtain "chemical vacation" from intolerable drives with the help of drugs. The choice of the drug would depend on his personality traits, e.g., an extrovert person would prefer stimulant drugs like amphetamine while an introvert person would like to go for opioids or barbiturates. If the drug provides a quick and better relief, the tendency to reinforce increases. That means in whenever a "drive state" arises next time, the

desire to seek the drug will be reinforced. The reinforcement power of the commonly abused drugs is given below (Fig. 38.2).

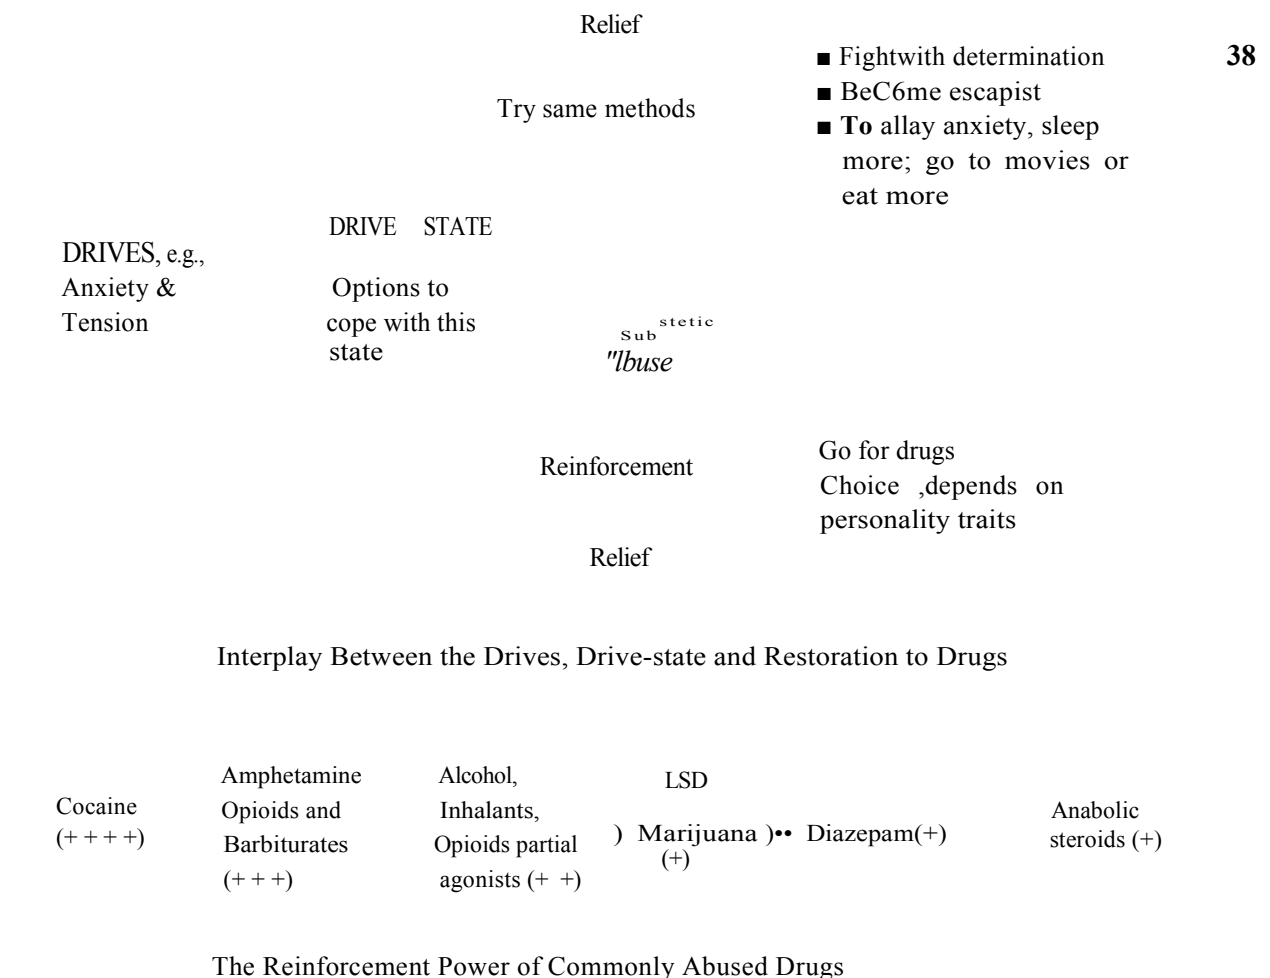

DRUGS OF ABUSE THAT ENGENDER DEPENDENCE

Agents having only mild psychological (psychic) dependence (low withdrawal, no physical dependence)

Coffee, Tea, Cigarette smoking (up to 10 cigarettes a day, without inhalation).

■ *Agents with moderate to severe psychological dependence (low withdrawal, slight physical dependence).*

Marijuana, Hashish (psychic dependence mild; physical dependence doubtful; tolerance may develop). **LSD** (psychic dependence mild, physical dependence nil, tolerance ±). Amphetamines, Cocaine (psychic dependence severe, physical dependence mild, tolerance mild).

Nicotine (20 cigarettes or more a day with inhalation) (psychological dependence severe, physical dependence mild, withdrawal effects low). Inhalants (psychic dependence moderate, physical dependence nil, withdrawal effects low, tolerance +).

- *Agents having moderate to severe psychological dependence with mild physical dependence*

Benzodiazepines (moderate psychic dependence, mild physical dependence on moderate and prolonged use, withdrawal effects mild, tolerance occurs, mechanism uncertain — self induction?)

Alcohol (moderate use) (severe psychic dependence, mild physical dependence, mild withdrawal effects, tolerance develops).

- *Agents having severe psychological and physical dependence*

Opioids (severe psychic as well as physical dependence, pharmacodynamic tolerance marked, withdrawal effects severe and precipitated by naloxone).

Barbiturates (severe psychic as well as physical dependence, withdrawal effects severe, pharmacokinetic type of tolerance)

Alcohol (heavy use) (severe psychic dependence, moderate physical dependence on prolonged use, tolerance occurs, withdrawal effects severe).

Abuse potential of these drugs has been discussed in earlier chapters.

NEUROPHARMACOLOGY OF THE REWARD AND REINFORCEMENT

Almost all dependence-producing drugs activate the "reward-reinforcement pathway" called the mesolimbic dopaminergic pathway. Some even consider this to be the "pleasure centre" of the brain and dopamine as a "pleasure neurotransmitter". Even though the primary sites of action of dependence producing drugs are different and generally elsewhere in the brain, all these drugs increase the release of dopamine in the nucleus accumbens. Although opioids and 5 receptors), cannabinoids (CBI receptor), amphetamine, cocaine

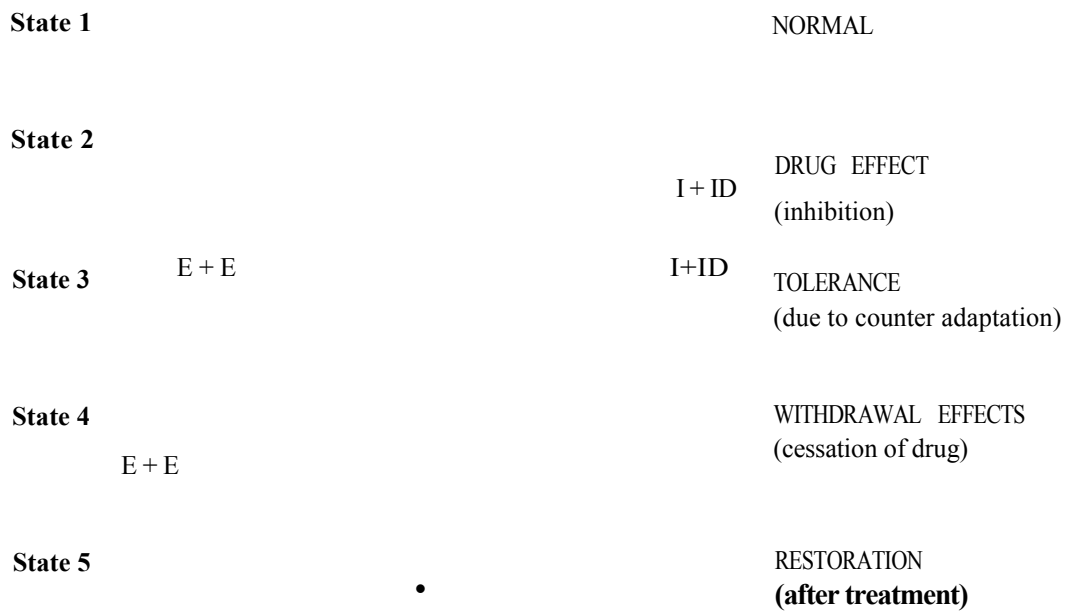

(dopamine transporters), barbiturates (Cr channel of GABA receptor), nicotine (Nat channel linked to nicotinic receptor) and ethanol (Ca²⁺ channel linked to NMDA receptor) elicit their acute behavioural effects by different mechanisms, the ultimate drug actions at these targets lead to an elevation of extracellular DA levels in nucleus accumbens.

D₂ receptor antagonists injected into the mesolimbic area of the brain reduce the self-administration of the drug in rodents. Similarly, removal of D₂ receptors in a transgenic mouse strain, eliminated the reward and reinforcement properties of morphine administration, without eliminating other opioid effects including withdrawal effects.

MECHANISMS FOR THE DEVELOPMENT OF TOLERANCE, DEPENDENCE AND WITHDRAWAL EFFECTS

In the major areas of brain, usually there is a balance between an excitatory (E) and inhibitory (I) neurotransmitter (Fig. 38.3, state-1) and the body tries to counteract the stimulant or depressant effects of the abused drug, if it is subjected to prolonged use, by increasing the inhibitory or excitatory activity, respectively. In this figure, the abused drug shown is inhibitory (ID), which mimics the inhibitory neurotransmitter (I). As a result of its primary action, the balance would be altered to a state of inhibition (I + ID) or depression (state 2). After its prolonged use, the body would try to increase the excitatory activity (as counteradaptation, E + E). The balance (E + E = I + ID) would then be restored and the increasing doses of the drug would now be required to obtain the same inhibitory effects of the drug (i.e., tolerance develops, state 3).

If this drug (ID) is suddenly withdrawn, a disbalance would occur which must obviously produce effects and symptoms opposite to those of the drug (withdrawal effects, state 4). The latent hyperexcitability in such a situation is unmasked (E + E) because physiological restoration of normal balance would take its own time. The biological restoration to normal levels could also be achieved by proper treatment (state 5) (see below). However, the state of inhibition (I + ID), to which the addict was used

Key: E—Excitatory neurotransmitter; I—Inhibitory neurotransmitter;
ID—Inhibitory (depressant) drug.

A Model of CNS Counteradaptation After Drug Abuse

to, could be obtained by providing him the same drug (ID). The very fact that the discontinuance of an abused drug may precipitate withdrawal symptoms provides an incentive to continue its use. If a physically dependent addict oscillates between feelings of euphoria and thereafter dysphoria, related to withdrawal, he would exhibit drug seeking behaviour to negate the unpleasant feelings.

Dependence is more commonly associated with abuse of short to intermediate acting drugs such as *secobarbital*, *pentobarbital*, *lorazepam*, *alprazolam*, *pethidine*, *morphine* and *heroin* etc. Dependence on longer acting agents such as *phenobarbital*, *chordiazepoxide*, *flurazepam* or *methadone* is less common because drugs with longer half-lives produce a less severe withdrawal syndrome, that too of longer duration. Dependence is rarely associated with intravenously administered ultra-short acting drugs like *pentothal*, *methohexital*, *midazolam* and *fentanyl* derivatives because these agents cannot be taken frequently enough to maintain adequate plasma concentrations needed to avoid withdrawal effects.

NEUROPHARMACOLOGICAL ADAPTATIONS DURING DEPENDENCE 38

For each class of abused drugs (benzodiazepines and barbiturates Ch. 32; amphetamines, cocaine and cannabinoids Ch. 35; alcohol Ch. 36 and opioids Ch. 37), the neuropharmacological mechanisms involved in the development of tolerance, dependence and withdrawal have already been described. We, hereby, summarise as to how chronic exposure to drugs of abuse induces adaptive changes in neuronal signal transduction pathways.

- *Chronic exposure to ethanol* leads to compensatory increase in the density of NMDA receptors and L-type voltage-gated Ca²⁺ channels in the brain. This leads to neuronal hyperactivity observed during alcohol withdrawal. NMDA and L-type channel antagonists, therefore, decrease withdrawal effects of alcohol in rodents. Chronic exposure to ethanol also down-regulates the GABAA receptor activity. This also contributes to alcohol withdrawal. Benzodiazepines, therefore, due to their GABAergic properties are useful in reducing alcohol withdrawal symptoms. Ethanol

also up-regulates cAMP-mediated signaling in other brain areas including midbrain ventral tegmental area (VTA) and nucleus accumbens.

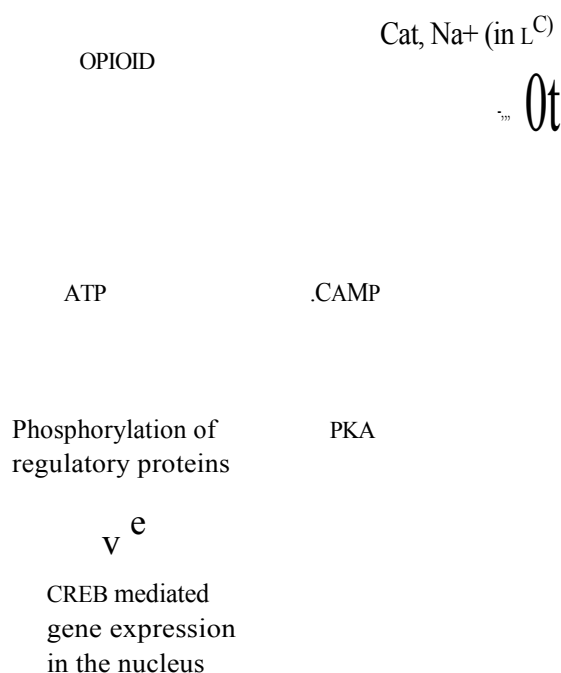

- *Opioids, on brief exposure*, activate μ receptors leading to Gi-mediated inhibition of adenylyl cyclase (AC) and consequently of cAMP, protein kinase-A (PKA) and voltage-gated N-type Ca^{2+} channels but an activation of K^{+} channel, all leading to a decrease in cellular excitability (Ch. 37, Fig. 37.3). *Chronic exposure of opioids*, on the other hand, induces a compensatory rise in AC, cAMP, PKA and cAMP response element binding protein (CREB). Simultaneously, the increased cAMP signaling in locus coeruleus enhances functioning of Na^{+} channels by promoting NE release. Hyperactivity of this adrenergic nucleus (locus coeruleus) has been implicated in opioid withdrawal. The up-regulation of CREB also mediates cAMP-depen-

dent gene expression. All these changes increase the intrinsic firing rate of neurons in locus coeruleus partly through activation of an inward Na^{+} current (Fig. 38.4; see also Fig. 37.2). Thus the up-regulation of cAMP signaling cascade not only opposes the acute inhibitory actions of opioids but also contributes to opioid tolerance as well as hyperexcitability during opioid withdrawal. It has been reported that animals lacking CREB show reduced withdrawal symptoms of opioid drugs.

- *Chronic exposure to cocaine and amphetamines* also leads to compensatory up-regulation of cAMP signaling in nucleus accumbens which contributes to psychostimulant tolerance, because pharmacological activation of PKA or overexpression of CREB in nucleus accumbens decrease the rewarding properties of cocaine. The receptor neuroimaging studies have demonstrated that chronic abuse of cocaine down-regulates D₁ receptors and up-regulates dopamine transporters. Normally, *on brief exposure*, cocaine binds to dopamine transporters and inhibits dopamine reuptake; while amphetamine causes intracellular release of dopamine from its vesicles and then reverse transports this dopamine through dopamine transporters. These actions serve to elevate the extracellular levels of dopamine in the synaptic cleft (Ch. 35).

- At a cellular level *nicotine* acts on nicotinic-acetylcholine receptors (NN) to produce neuronal excitation. *Its reinforcing properties* are associated with increased activity in the mesolimbic dopaminergic pathway as discussed above. Effects of nicotine are mediated by enhancing the permeability of Na^{+} through nicotinic-cholinergic receptor gated Na^{+} channels. *Chronic*

exposure of nicotine desensitises these receptors, channels in locus coeruleus (LC), following chronic exposure to opioids (see text).

Bold arrows indicate compensatory increases in adenylyl cyclase (AC), cAMP, protein kinase-A (PKA) and cAMP response element binding protein (CREB) levels and increased function of Na^{+}

but simultaneously also leads to a substantial increase in the number of these receptors (an effect opposite to that produced by chronic administration of most dependence-producing drugs). It may represent an adaptive response to prolonged receptor desensitisation.

The overall effect of nicotine may reflect a balance between the activation of neuronal

nicotinic receptors (causing normal excitation) and the abused drug by a similar drug having longer the desensitisation (causing synaptic block). plasma half-life, (b) an aversive therapy by using a However, as the cellular effects of nicotine get drug which produces unpleasant response after an diminished, after chronic exposure, it is also intake of the abused drug, (c) use of a proper possible that the additional binding sites represent the desensitised rather than functional receptors. antagonist, to prevent relapse, once the drug free status is achieved, (d) use of such drugs which reduce craving for the abused drug and (e) rehabilitation and psychosocial interventions. Withdrawal effects of benzodiazepines and barbiturates (Ch. 32), amphetamines, cocaine and cannabinoids (Ch. 35); alcohol (Ch.36) and opioids (Ch. 37) have already been discussed earlier, hence treatment of their withdrawal effects is discussed below.

- *Cannabinoids* and opioids share common signaling pathways in the brain for reward and reinforcement but as there is hardly any physical dependence or withdrawal syndrome developing with the use of cannabinoid, the associated neuroadaptive mechanisms have little relevance if any.

DESIGNER DRUGS

Designer drugs are synthetic substances, prepared in clandestine laboratories, that are inexpensive to produce and difficult to detect. Such molecular manipulations of the widely abused drugs are done by some chemists to avoid Drugs and Narcotic Act regulations and to make huge profits. These include the amphetamine analogue, 3,4-methylenedioxymethamphetamine (MDMA), known as "Ecstasy" on the streets. Another is "China White" which is a synthetic analogue of fentanyl with 1000-1500 times of its potency. The consequences of "designer drug abuse" are, however, unpredictable and in some instances lethal. For example, efforts to make pethidine analogue *levo-alfa-acetyl methadol* (LAAM), with substitute resulted in an end product, methyl-phenyl-tetrahydropyridine (MPTP) which unfortunately can also be used, but with a caution as it prolongs QT causes nigrostriatal lesions and produces parkinsonism. It is now used as pharmacological tool to produce parkinsonism. One can easily imagine what kind of future holds to individuals and for the society with such clandestine activities around.

TREATMENT OF DRUG DEPENDENCE

The ultimate goal of treatment program is to achieve a "drug free status" as early as possible and to prevent the relapse of drug abuse. The drug free status is achieved with the help of pharmacotherapy while "relapse prevention strategies" involve rehabilitation and psychosocial interventions. The pharmacological approaches to treat drug dependence and withdrawal include: (a) short-term or long-term substitution of

Treatment of Opioid Dependence

Substitution Therapy

The most commonly used strategy is to switch the patient from a short-acting opioid, such as heroin, to a long-acting agonist such as *methadone*. With such a substitution, the addict is spared from the undesirable effects of withdrawal because the opioid receptors remain occupied for a longer duration. Thereafter, methadone can be withdrawn in tapering doses over a period of weeks. The pharmacological basis of using *methadone* depends on its oral effectiveness (once daily dosing), longer duration of action and development of cross tolerance between it and other opioids. An even longer acting analogue *levo-alfa-acetyl methadol* (LAAM), with substitute resulted in an end product, methyl-phenyl-tetrahydropyridine (MPTP) which unfortunately can also be used, but with a caution as it prolongs QT causes nigrostriatal lesions and produces parkinsonism. It is now used as pharmacological tool to produce parkinsonism. One can easily imagine what kind of future holds to individuals and for the society with such clandestine activities around.

Use of an Opioid Antagonist

A long-acting, orally active opioid antagonist *naltrexone* provides another treatment option in that the addicts who are completely withdrawn from opioid (after methadone therapy) can be maintained in such a state further, to block pleasurable effects leading to relapse. It can be given three times a week in doses of 100-150 mg (or 50 mg OD) or in the form of depot injection on monthly basis. However, the therapy is successful only if the patient is already detoxified and is "opioid free" for the past 10 days; otherwise, the opioid withdrawal effects would be precipitated.

Use of Clonidine or lofexidine

To detoxify the patient and to prevent relapse, *clonidine*, a centrally acting sympatholytic agent, can also be used. By reducing the central NE outflow from locus ceruleus, clonidine reduces the severity of distressful withdrawal effects of opioids such as hypertension, anxiety, headache, tremors, intestinal cramps and diarrhoea. *Lofexidine* causes lesser hypotension compared to clonidine. Both have no narcotic action and are not addictive.

Rehabilitation and Other Aspects

The pharmacotherapy is more rewarding if combined with rehabilitation program which includes proper education and counselling. Besides treating withdrawal and dependence, all possible efforts should be made to prevent AIDS, hepatitis, bacterial endocarditis and other consequences of contaminated needle exchange between I.V. opioid dependent addicts.

Treatment of Alcoholism

The treatment of both acute and chronic alcoholism has already been discussed in detail in Chapter 36.

Treatment of Barbiturates and Benzodiazepines Dependence

If short-acting barbiturates such as *pentobarbital* or *secobarbital* have been abused, a long-acting barbiturate such as *phenobarbital* may be substituted as a pharmacologically equivalent drug and then gradually withdrawn with tapering doses. If a long-acting barbiturate is abused, the same drug is allowed to continue but it is gradually withdrawn at a rate of 10% of the daily requirement. Complete detoxification may be achieved in 2-3 weeks duration.

For detoxification of barbiturates, an osmotic diuretic with sodium bicarbonate can also be used to alkalinise the urine and to hasten the elimination of the drug. During this period the abused barbiturate may also be substituted with an antihistamine (*diphenhydramine*) for symptomatic treatment of withdrawal effects. The latter may then be withdrawn after successful detoxification. Seizures represent a medical emergency during withdrawal and can be treated by parenteral administration of *diazepam* or *carbamazepine*.

With benzodiazepines (BZDs) the physical

dependence is rare, but may occur following long-term treatment with doses of 40 mg/day or more of diazepam. Nonetheless, if an intermediate to short acting BZD has been abused, a long acting BZD such as *chlordiazepoxide* can be substituted as the pharmacologically equivalent drug which can be subsequently withdrawn in tapering doses. The BZD receptor antagonist *flumazenil* can be used to specifically block the toxicity of BZDs overdose or to prevent relapse after detoxification.

Treatment of Nicotine Dependence

Nicotine dependence has already been discussed in detail in Ch. 13.

Treatment of Withdrawal From Stimulants and Psychotomimetics

The pharmacological approach towards the management of withdrawal from amphetamines, phencyclidine, cocaine, LSD and marijuana have already been dealt in Chapter 35.

Treatment of Withdrawal From Inhalants

There is little evidence that the signs of abstinence occur in individuals when inhalants are withdrawn, suggesting that physical dependence is not the part of the experience of these abusers. Since abusers are still taking these agents repeatedly there seems to be some psychic dependence on them. No specific treatment is available because the toxic effects of inhaled solvents and aerosols may be caused by more than one substance and also because solvents typically contain more than one volatile compound. These may be tainted also with heavy metals such as lead, mercury, nickel and cadmium. Rehabilitation and education of such patients is more rewarding.

Withdrawal From Anabolic Steroids

Patients abusing anabolic steroids, e.g., *stanozolol* for body building, are seldom covered by deaddiction programs. Yet, they may come to deaddiction centres if they suffer from excessive aggression, sexual dysfunction or mood fluctuations. Again, mere counseling may suffice, with gradual withdrawal of the anabolic steroid. Such patients may also be advised to avoid going to gyms as these are the favourable sites for acquisition of steroids.

Brief history of toxicology

History of toxicology = history of the human race

The early humans must have learnt to discriminate between things that were good to eat and those that were not

Natural progression → hunting
warfare
homicide

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

- Arrow poisons were developed by ancient peoples in all parts of the world, and many are still in use (Masai hunters – 18000 years ago).

Phylllobates terribilis

Diamphidia nigro-ornata (Bushman arrow-poison beetle)

Strychnos toxifera

Brief history of toxicology

Ebers Papyrus (~1500 B.C.)

- The oldest well preserved medical document
- Contains 110 pages on anatomy and physiology, toxicology, spells, and treatment recorded
- More than 800 medicinal and poisonous recipes, many contain recognized poisons (opium, hemlock, lead...)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Socrates (470-399 B.C.)

He was found guilty of corrupting the minds of the youth of Athens and sentenced to death by drinking a mixture containing poison hemlock.

Brief history of toxicology

Cleopatra – Queen of Egypt (69-30 B.C.)

Experimented with strychnine and other poisons on prisoners and poor. Committed suicide with Egyptian Asp (Egyptian cobra sometimes used in executions).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dioscorides (40-90 A.D.)

Greek physician who classified poisons for Nero. Wrote the *Materia Medica* (5 volumes) documenting over 600 medicinal plants he encountered while traveling with the Roman military, as well as earlier compilations of Roman and Greek knowledge.

This was a standard text for 16 centuries!

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

Swiss physician Paracelsus (1493-1541) credited with being **“the father of modern toxicology.”**

“All substances are poisons: there is none which is not a poison. The right dose differentiates a poison from a remedy.”

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Catherine Medici (1519-1589)

She often used poisoning as a political tool during her reign.
She experimented with poisons on the sick and poor to develop more advanced poisons.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

Mathieu Orfila (1787 - 1853)

Established a systematic correlation between the chemical and biological properties of poisons.

He demonstrated effects of poisons on specific organs by analyzing autopsy materials for poisons and their associated tissue damage.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

20th Century

Chemical Warfare (1915)

By the middle of the 1910's, chemicals had been developed to be used by the military as weapons. Agents such as Chlorine, Chloropicrin, Phosgene and Mustard gas were all used in chemical warfare. Humans and dogs were fitted with gas masks.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

20th Century

Gerhard Schrader (1903-1990)

Accidentally developed the toxic nerve agents Sarin, Tabun, Soman, and Cyclosarin while attempting to develop new insecticides. As a result, these highly toxic gases were utilized during World War II by the Nazi's. He is sometimes called the "father of the nerve agents".

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

20th Century

DDT – 1939

Paul Hermann Müller

Recognized as insecticide by the Swiss scientist Paul Hermann Müller, who was awarded the 1948 Nobel Prize in Physiology and Medicine. DDT was banned in late sixties and early seventies.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

20th Century

Rachel Carson - alarmed public about dangers of pesticides in the environment.

Human role in ecology and as well as safety from pesticides were some of the fields she worked in.

Scientist leads crusade against the use of DDT, a pesticide and persistent organic pollutant.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Basic terms of toxicology

DIFFERENT AREAS OF TOXICOLOGY

CLINICAL TOXICOLOGY

Clinical toxicologists usually are physicians or veterinarians interested in the prevention, diagnosis, and treatment of poisoning cases.

They have specialized training in emergency medicine and poison management.

EXPERIMENTAL TOXICOLOGY

Experimental toxicologists study the harmful effects of chemical substances on living animals (mechanism of action, disposition, analytical procedures).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Basic terms of toxicology

ENVIRONMENTAL TOXICOLOGY

Environmental toxicologists study the effects of pollutants on organisms, populations, ecosystems, and the biosphere.

FOOD TOXICOLOGY

Food toxicologists deal with the possible deleterious effects of chemicals in food for human consumption (residue level).

FORENSIC TOXICOLOGY

Forensic toxicologists study the application of toxicology to the law. They use chemical analysis to determine the cause and circumstances of death in a postmortem investigation.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

OTHER SPECIAL AREAS

Industrial toxicology

Occupational toxicology

Regulatory toxicology

Regulatory toxicologists use scientific data to decide how to protect humans and animals from excessive risk.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

WHAT IS TOXICOLOGY?

THE STUDY OF THE ADVERSE EFFECTS OF CHEMICAL AGENTS ON LIVING ORGANISMS.

ADVERSE EFFECTS

- any change from an organism's normal state
- dependent upon the concentration of active compound at the target site for a sufficient time

POISON = TOXICANT

- inorganic and organic lifeless substances
- any substance that causes deleterious effects in a living organism

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

POISONS

- biologic origin (nicotine, botulinum toxin)
- naturally-occurring chemical element (Pb,Cu)
- manufactured chemicals (pesticides)
- results of a physical process (CO)

“Synthetic” does not mean toxic or poisonous

“Natural” does not mean safe or even low risk

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Basic terms of toxicology

TOXIN

Poisonous substance produced by a living organism, such as a plant, animal or micro-organism

Phytotoxins
Zootoxins
Bacteriotoxins
Mycotoxins

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

XENOBIOTIC

A chemical compound that is foreign to the body or to living organisms.

(xenos-strange, bios-life)

TOXICOSIS = POISONING = INTOXICATION

Describes the disease state which results from exposure to a poison.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

TOXIC SYMPTOM

It is any feeling or sign indicating the presence of a poison in the system.

TOXIC EFFECTS

It refers to the health effects that occur due to exposure to a toxic substance.

TOXICITY

The adverse effects that a chemical may produce.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Basic terms of toxicology

EXPOSURE

The actual contact of the chemical substance with the biological organism.

(It means contact with a hazard.)

HAZARD

It is a chemical substance, physical agent, or biological agent that can harm the health of people.

The likelihood that the toxicity will be expressed.

Risk = Hazard X Exposure

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

The Dose Makes the Poison

An apparently nontoxic chemical can be toxic at high doses. (Too much of a good thing can be bad.)

Highly toxic chemicals can be life saving when given in appropriate doses. (Poisons are not harmful at a sufficiently low dose.)

Terms defining toxicity: The Median Lethal Dosage

LD₅₀

The amount (dosage) of a chemical substance that produces death in 50% of a population of test animals to which it is administered by any of a variety of methods.

mg/kg

Normally expressed as milligrams of chemical substance per kilogram of animal body weight.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose

Total amount of a chemical substance administered to an organism

Dosage

Characteristics of organism

Body weight

Surface area

Dosage is more precise (mg chemical substance/kg body weight)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Terms defining toxicity : The Median Lethal Concentration

LC₅₀

The concentration of a chemical substance that produces death in 50% of a population of test animals to which it is exposed.

mg/m³ , mg/l, mg/g(kg)

Normally expressed as milligrams of chemical substance per m³, l, g (kg) of the medium (air, water, soil...).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Basic terms of toxicology

Chemical substance	LD ₅₀ mg/kg b.w.
Ethyl alcohol	10 000.0
Sodium chloride	4 000.0
Morphin	900.0
Dithane M-45	10 700.0
Decis 2.5 EC	620.0
Temik 10 G	0.9
Nicotine	1.0
Aflatoxin B1	7.2
WX (chemical warfare)	0.015
Dioxin	0.001
Tityustoxin	0.009
Tetanus toxin	0.000002
Botulinum toxin	0.000001

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Classification of chemical substance based on toxicity

Toxicity class	LD ₅₀ mg/kg b.w.	Probable lethal oral dose for humans
Supertoxic	<5	a taste (less than 7 drops)
Extremely toxic	5-50	between 7 drops and teaspoonful
Very toxic	50-500	between teaspoonful and ounce (1/3 dl)
Moderately toxic	0.5-5 (g/kg)	a glass
Slightly toxic	5-15 (g/kg)	0.5-1 liter
Practical nontoxic	>15 (g/kg)	>1 liter

Local adverse effects

The site of action takes places at the point of contact.

The site:

- skin
- mucous membrane of the eyes, nose, mouth, throat
- or anywhere the along the respiratory or gastrointestinal system

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Systemic adverse effects

Requires absorption and distribution to a distant site.
Most chemical substances can produce systemic effects

Target organs:

CNS, circulatory system, blood and hematopoietic system, liver or GI, kidney, lung

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Cumulative Effects

Over a period of time, the material is only partially excreted and the remaining quantities are gradually collected.

The retained toxic compound accumulates and becomes great enough to cause adverse effect.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Immediate / Delayed Toxicity

Immediate

Develops rapidly after a single administration of a substance.

Delayed

Toxic effects occur after the lapse of some period of time.

Carcinogenic effects have long latency (up to 30 years).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Reversible / Irreversible Toxic Effects

Some toxic effects are reversible, and others are irreversible.

Level of tissue injury

- Liver has high regenerative ability (most are reversible)
- Central nervous system have differentiated cells (largely irreversible)
- Carcinogenic and teratogenic???

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Basic terms of toxicology

Various interactions of chemical substances

Additive

Combined effect of two chemicals is equal to the sum of the effects of each ($2+3=5$).

Synergistic

Combined effect of two chemicals are much greater than the sum ($2+2=20$).

Potentiation

One substance does not have a toxic effect on a certain organ or system but when added to another chemical is already toxic.

Antagonism

Two chemicals interfere with each others in actions.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Exposure

The actual contact of the chemical substance with the biological organism.

Routes and Sites of Exposure

- Ingestion (Gastrointestinal Tract – food and water)
- Inhalation (Lungs - air)
- Dermal/Topical (Skin)
- Injection (intravenous, intramuscular, intraperitoneal...)

Typical Effectiveness of Route of Exposure

i.v. > inhale > i.p. > i.m. > ingest > topical

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Duration and Frequency of Exposure

Acute

A single exposure lasting less than 24 hours.

Subacute

Repeated exposure lasting 1 month or less.

Subchronic

Repeated exposure lasting from 1 month to 3 months.

Chronic

Repeated exposure lasting more than 3 months (over months or years).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ACUTE POISONING

The body is exposed to the toxic substance in a single high dose.

Symptoms of poisoning develop in close relation to the exposure (within hours or days).

CHRONIC POISONING

The body is exposed repeatedly to toxic substance in low dose during a long period .

Symptoms of poisoning are appeared after a long period (months or years).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose-response relationship

Paracelsus was the first to recognize the concept of dose.

Fundamental concept in toxicology.

What is a toxic response?

- Death
- Pathological lesions
- Biochemical, pharmacological, or chemical change

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose-response relationships

Individual dose-response curve

- Response of an individual to varying doses of a chemical substance
- Graded response – continuous over a range of doses

Quantal dose-response curve

- Population
- Distribution of responses to different doses in a population of individual organisms

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose-response relationships

Symptoms

Concentration of CO in the blood

- 1- headache
- 2- dizziness
- 3- nausea, vomit
- 4- unconsciousness
- 5- death

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose-response relationships

As the dose of a toxicant increases, so does the response.

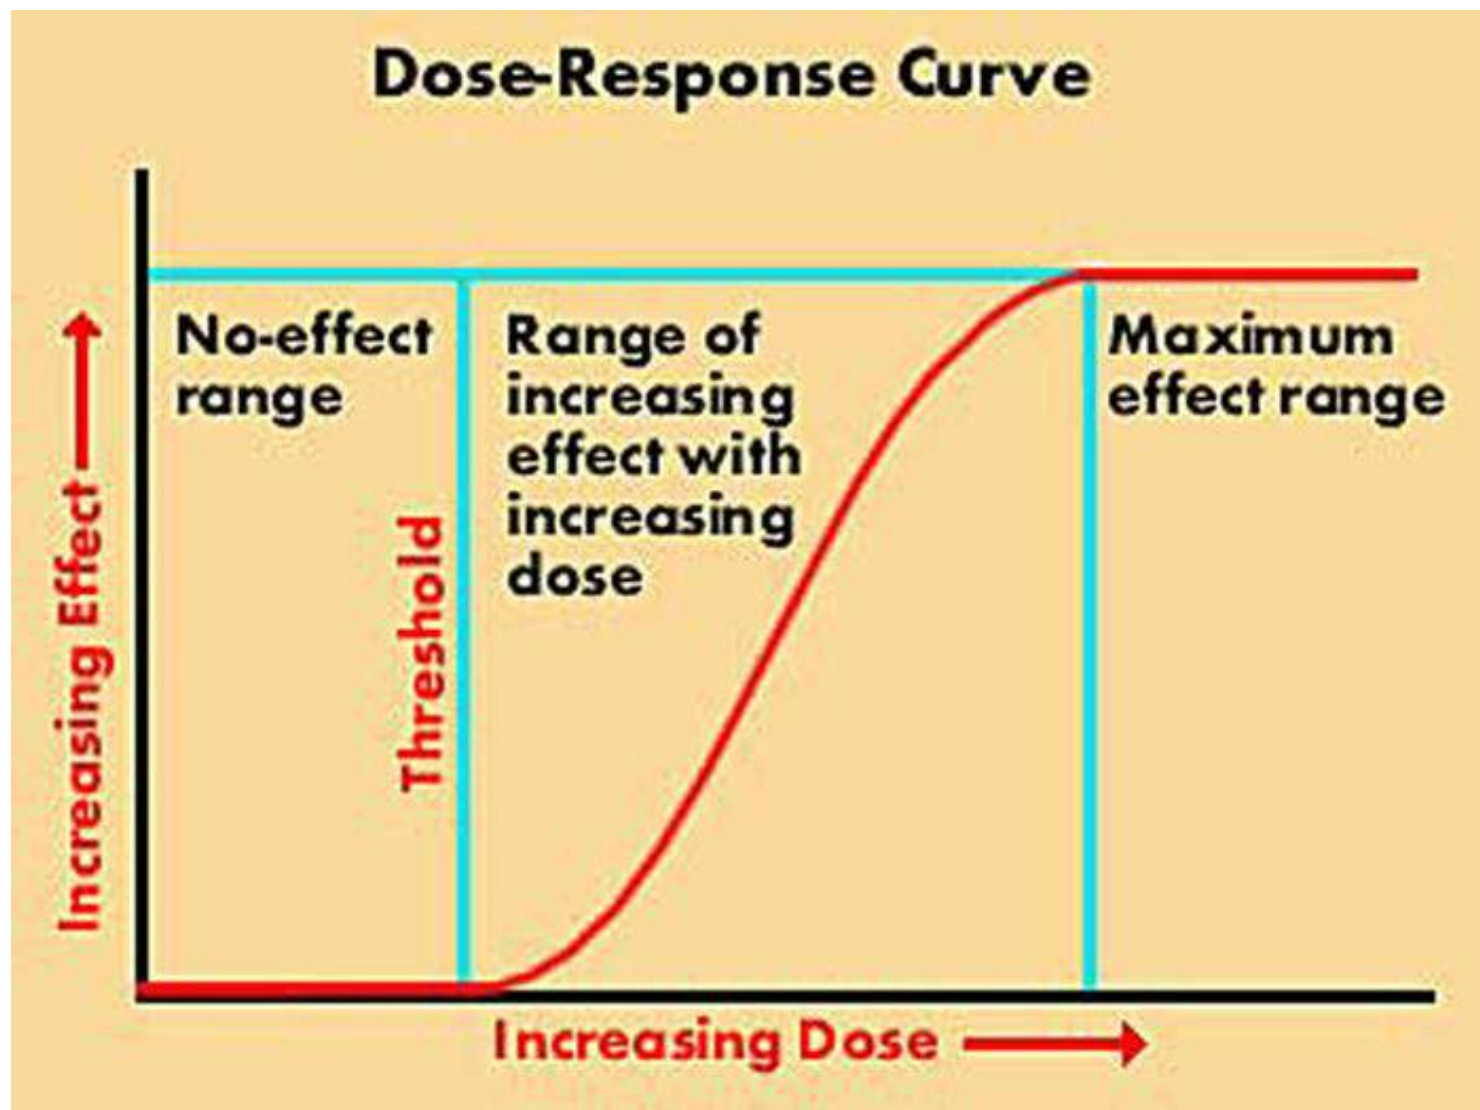

DOSE DETERMINES THE BIOLOGICAL RESPONSE

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose-response relationships

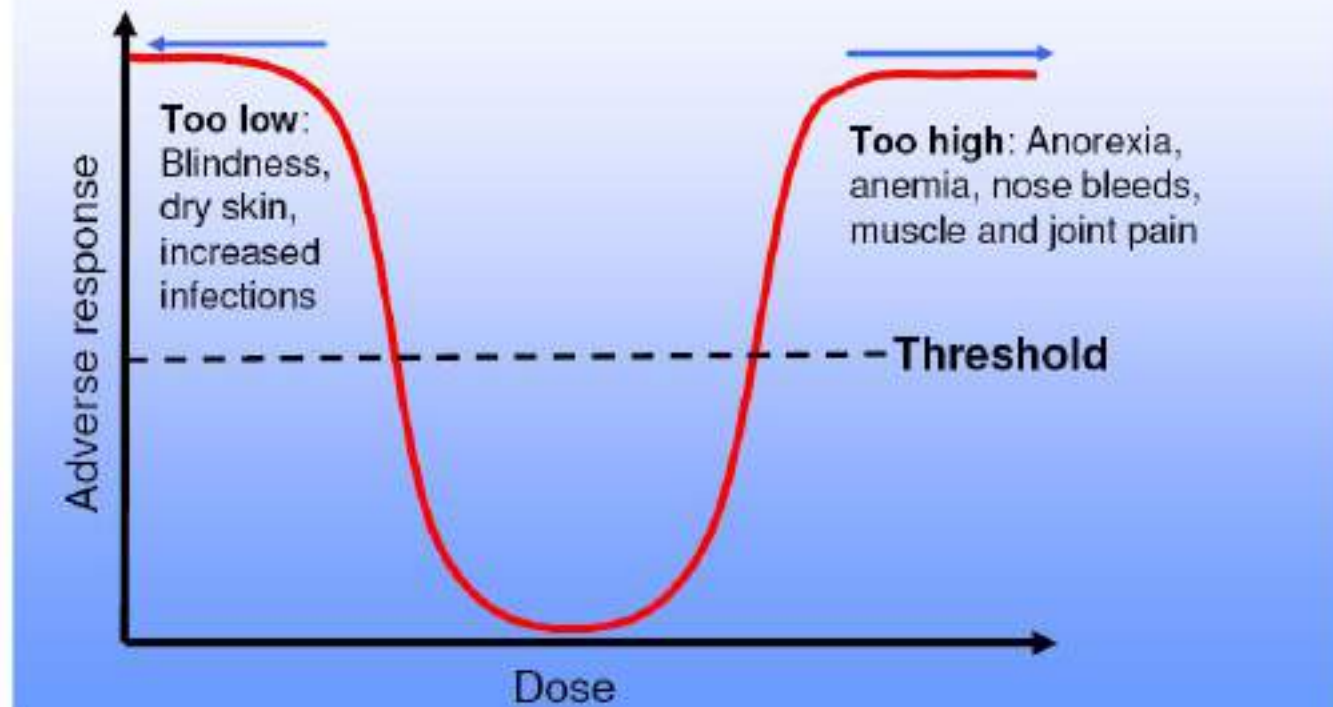

Dose-response relationships

If Mortality is the response, the dose that is lethal to 50% of the population LD₅₀ can be generated from the curve.

Dose-response relationships

Some chemicals have both therapeutic and toxic effects: Vitamin A

Dose-response relationships

Similar to LD_{50}

- ED_{50}
 - Effective dosage for 50 percent
- TD_{50}
 - Toxic dosage for 50 percent
- Therapeutic Index
 - Ratio of LD_{50} or TD_{50} to ED_{50}
 LD_{50}/ED_{50} or TD_{50}/ED_{50}

The larger value means the margin of safety between the effective dose and toxic dose is greater.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose-Response Relationship

"The Dose Makes the Poison"

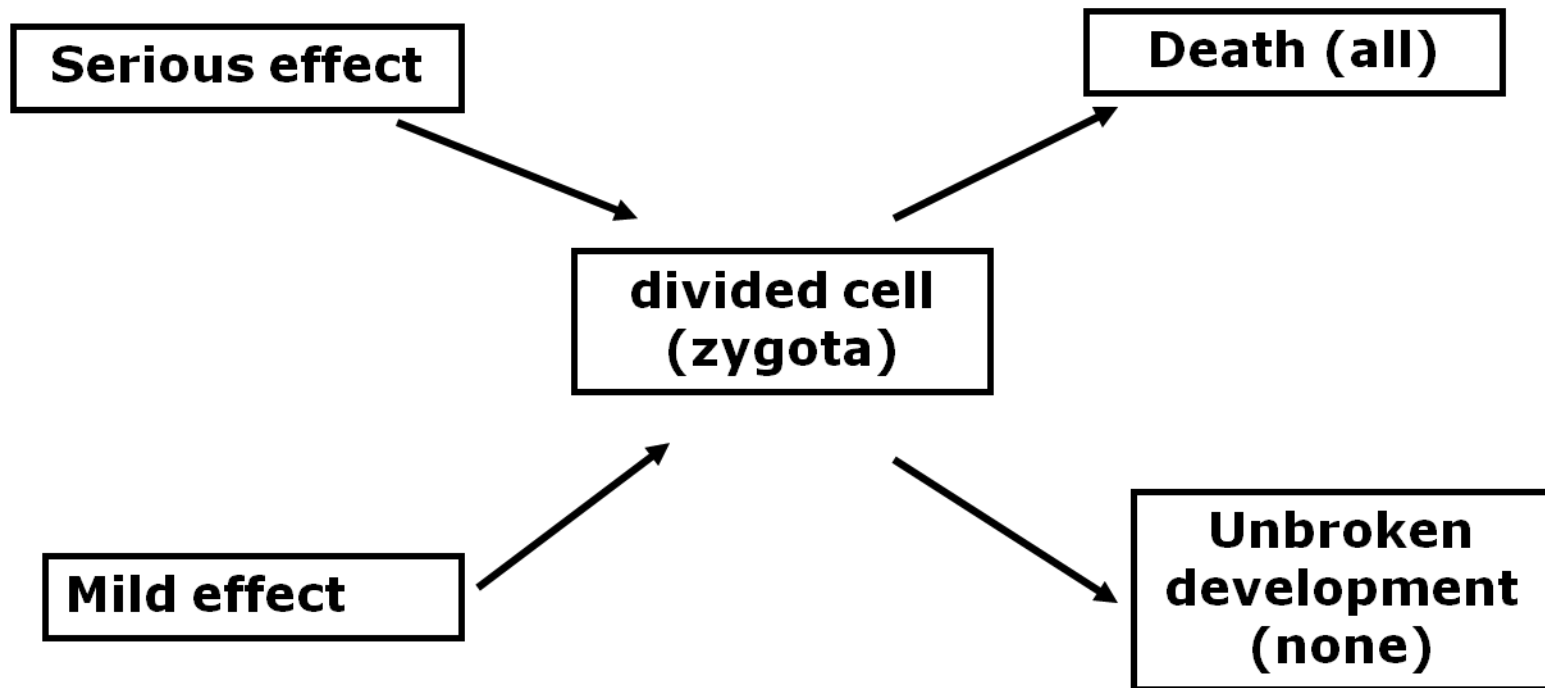

TOXICODYNAMIC PROCESS

- **CLASSIFICATION OF TOXIC EFFECT**
 - ⇒ character of toxic action
 - ⇒ mode of damaging
 - ⇒ site of damaging
 - ⇒ specific toxic effects

CHARACTER OF TOXIC ACTION

All-or-none

CHARACTER OF TOXIC ACTION

Graded – dose-dependent

⇒ NOEL (No Observed Effect Level)

majority of toxic agents

⇒ determine
threshold dose

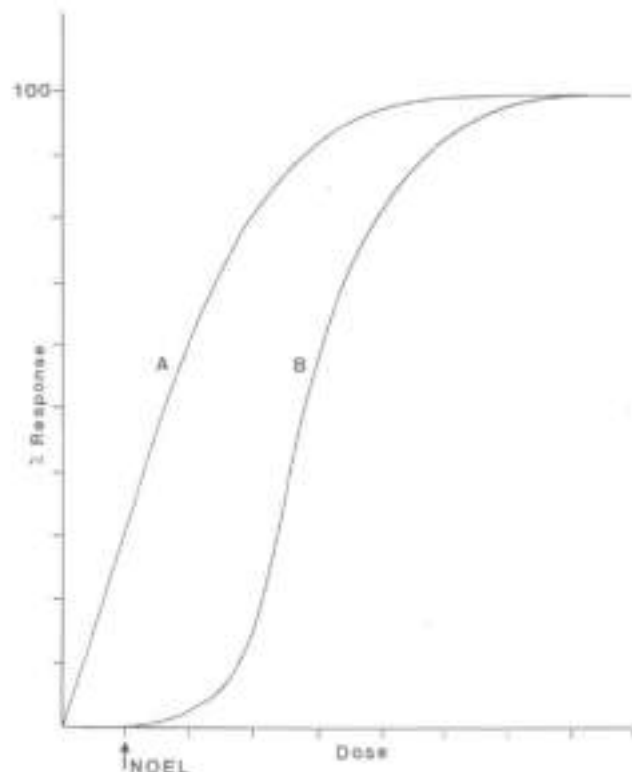

♦ below which

∅ detectable response

♦ above

dose-dependent response

⇒ ∅ threshold dose
(genotoxic carcinogens)

CHARACTER OF TOXIC ACTION

The threshold dose is an important one in toxicology particularly in terms of the **EXTRAPOLATION** of toxic dosis

- ⇒ derived from relatively small scale animal experiments
- ⇒ the subsequent assessment of risk to man

The NOEL is used in setting exposure limits:

➤ ADI – Acceptable Daily Intake (pesticides)

$$\text{ADI} = \frac{\text{NOEL mg/kg}}{\text{SF}}$$

TARGET POINT

General cell poison (acid, alkalis, As, Hg)

Cell and tissue specificity

⇒ **blood poison (CO - Hb)**

⇒ **nerve poison (Cl-CH - neuron)**

MODE OF DAMAGING

Physical interaction with cell constituents

independent from ⇒ fine structure of chemicals
 ⇒ species
generally reversible

⇒ direct action

acids, alkalis – skin, mucous membrane

⇒ change of character

organic solvent – lipid phase of membrane

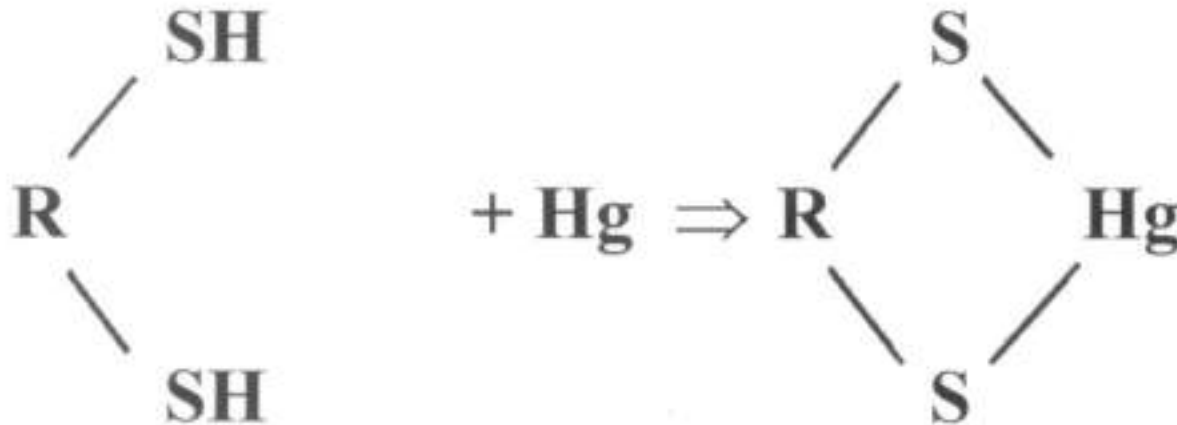

⇒ replacement of oxygen

gases – suffocation

MODE OF DAMAGING

Chemical

chemical substance + component of body = specific reaction
(heavy metals – SH-group, $\text{Se} \Rightarrow \text{S}$)

MODE OF DAMAGING

Biochemical

chemical substance + enzyme

depends on ⇒ fine structure of the chemicals
 ⇒ species

Physiologic

change of physiologic function of living organism
(nerve conduction velocity, body temperature, blood pressure)

SITE OF DAMAGING

CELL MEMBRANE

CELL METABOLISM

CELL NUCLEUS

DAMAGING OF CELL MEMBRANE

- NON-SPECIFIC
- SPECIFIC

NON SPECIFIC

- ⇒ cell death
 - detergents, alcohol
- ⇒ peroxidation of membrane lipids/proteins
 - paraquat, carbon tetrachloride, Cu

DAMAGING OF CELL MEMBRANE

SPECIFIC \Rightarrow selective damaging

\Rightarrow ION CHANNEL

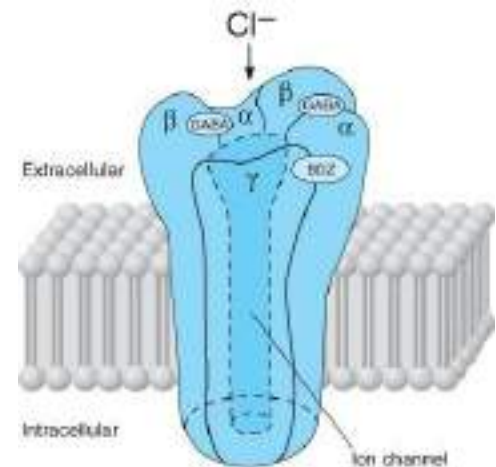

binding \rightarrow changing the membrane potential

\Rightarrow amino acid-receptor (GABA, glycine, glutamate)

change Cl-ion permeability

GABA-antagonist (Cl-CH)

inhibit the release of Cl \Rightarrow convulsion

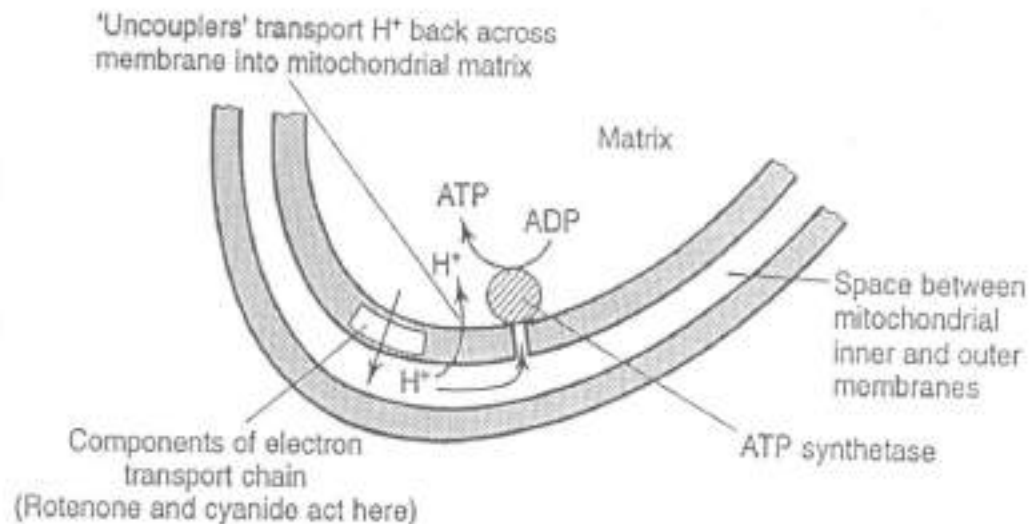

DAMAGING OF CELL METABOLISM

ELECTRON TRANSPORT (mitochondrion)

1⇒ inhibition of cellular respiration

inhibit ETC (NAD-NADH system +
blocking cytochrom oxidase
⇒ cytotoxic anoxia (cyanide)

DAMAGING OF CELL METABOLISM

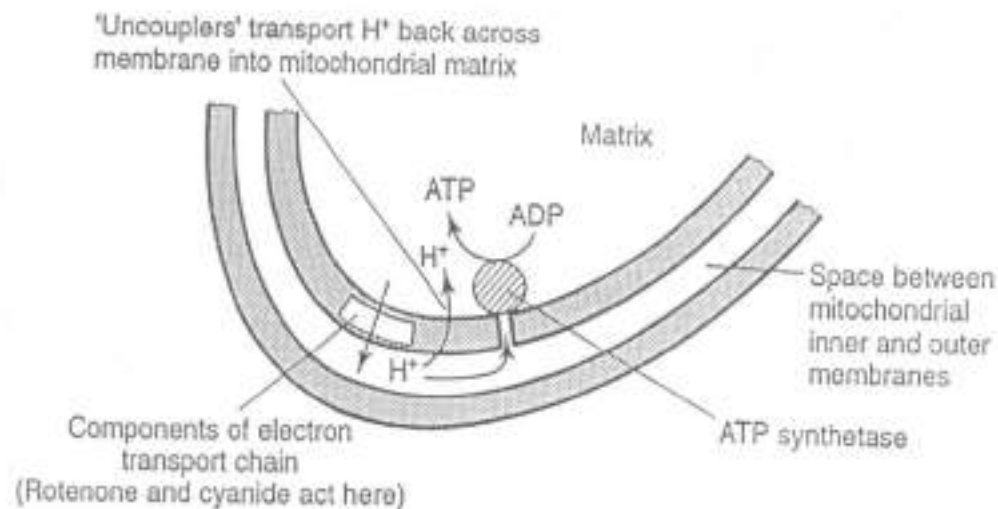

ELECTRON TRANSPORT (mitochondrion)

2⇒ uncoupling of oxidative phosphorylation

uncouple ATP production without blocking ETC

⇒ free energy \emptyset storage

⇒ body temperature \uparrow (dinitro/chloro-fenol)

DAMAGING OF CELL METABOLISM

INHIBITION OF NUCLEIC ACID/PROTEIN SYNTHESIS

- ⇒ alteration in replication/transcription
- ⇒ normal structural/enzyme proteins depleted
(aflatoxin, organomercurials)

INTERFERE WITH FAT MOBILIZATION

- ⇒ accumulation of it in the cell

DAMAGING OF CELL NUCLEUS

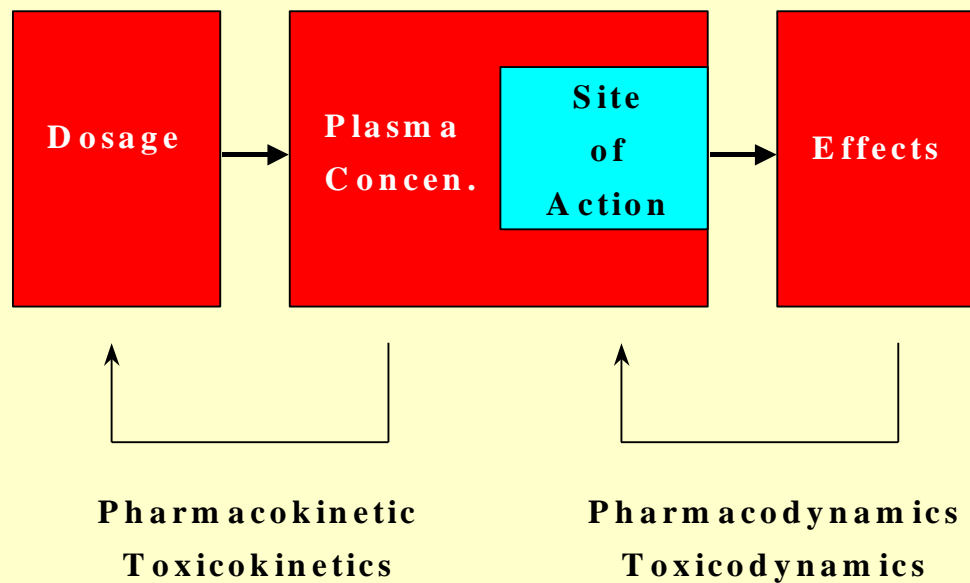

DAMAGE OF DNA

- ⇒ mutation ⇒ mutagenic effect
- ⇒ tumour formation ⇒ carcinogenic effect

GENOTOXIC CHEMICAL SUBSTANCES

alkylating agents (ethylene imine, β -propiolactone)
nitrosamines, PAH

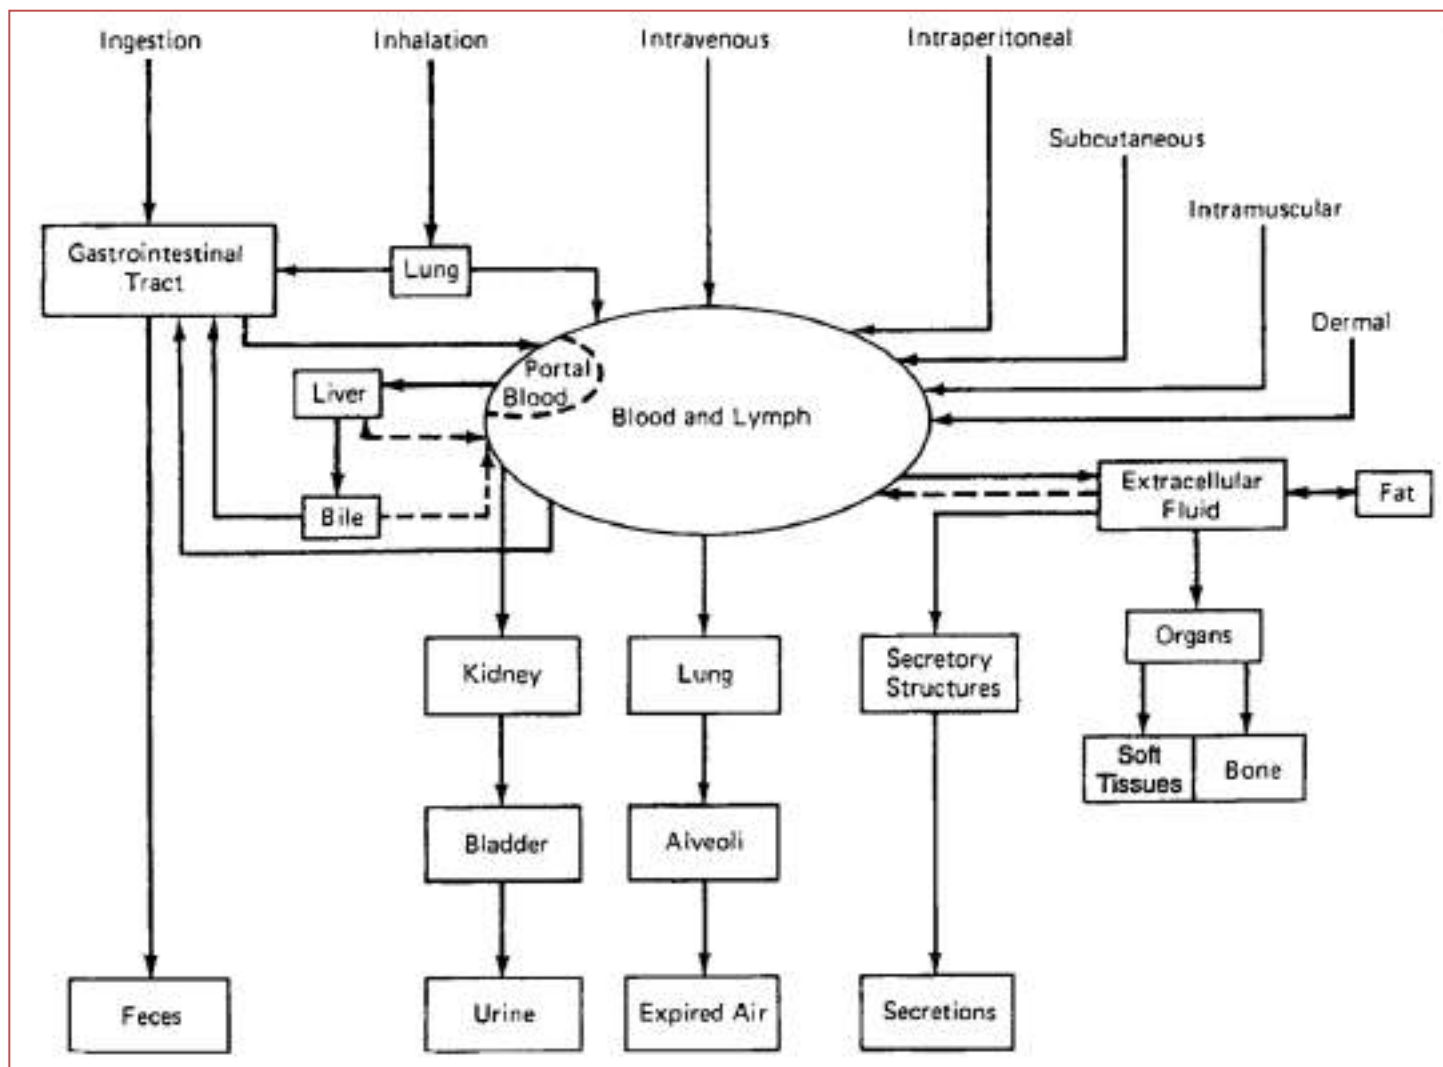

Toxicokinetics

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Toxicokinetics

Chemical substances need to achieve an adequate concentration in their target tissues. If the concentration of the toxic chemical remains low in the target organ of toxicity, little or no toxicity will result, whereas if high concentrations are attained, toxicity will result.

The two fundamental processes that determine the concentration of a chemical substance at any moment and in any region of the body are:

- translocation of chemical molecules,
- biotransformation by metabolism of chemical substance and other processes involved in elimination of chemical substance.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Absorption is the process of entry of chemical substance from site of exposure into systemic circulation.

It is the first step in the toxicokinetics of a chemical substance. If the fraction of the chemical substance absorbed is low or the rate of absorption is low, then only a low concentration of the chemical in the target organ may be obtained and thus no toxicity.

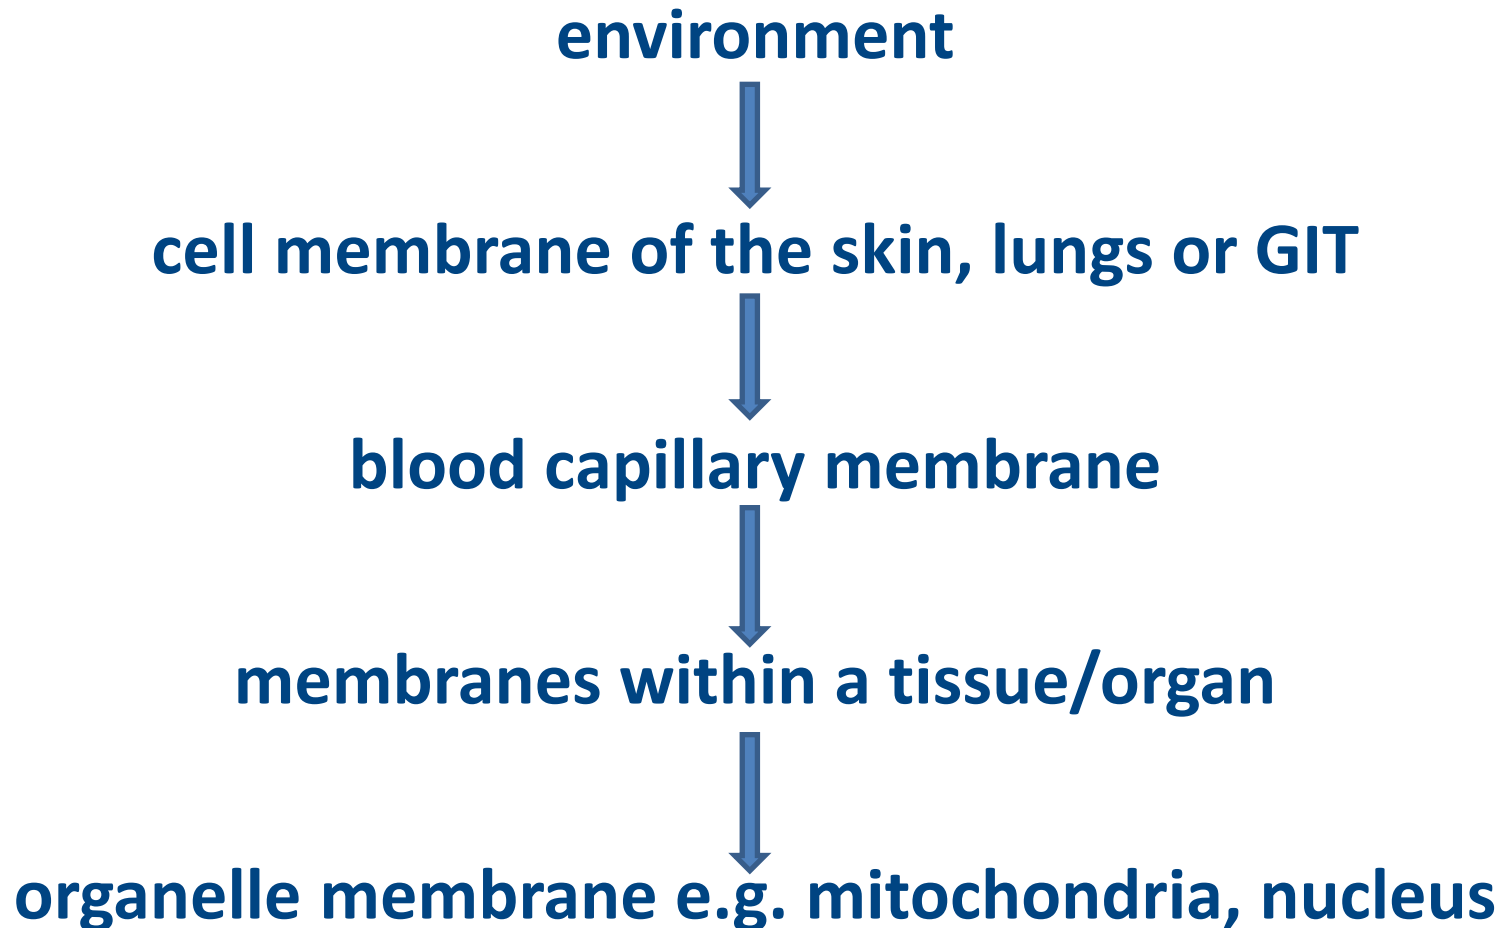

The skin, lung, GIT are the main barriers that separate humans or animals from toxic substances.

Chemical substances must cross one of these barriers to exert adverse effect on the body and then pass through various cell membrane.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Transport across membrane

Structure of membrane

phospholipids + proteins

Transport across membrane

Main properties of membranes

- Sensitivity to peroxidation
 - ⇒ free radicals can damage the membranes
- Selective permeability (semi-permeability)
 - ⇒ certain compounds ⇒ pass through

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Type of transportation

- ⇒ filtration
- ⇒ passive diffusion
- ⇒ active transport
- ⇒ facilitated diffusion
- ⇒ fagocytosis/pinocytosis

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Transport across membrane

Filtration

A difference in concentration of molecules in physical space is called a concentration gradient.

Transport across membrane

Passive diffusion

- ⇒ the most important transport
- ⇒ down a concentration gradient
- ⇒ influencing factors
 - thickness of membrane, surface size
 - concentration of toxic compound
 - lipid solubility
 - distribution coefficient, degree of ionization
- ⇒ rate of diffusion = $K \cdot A (C_2 - C_1)/d$

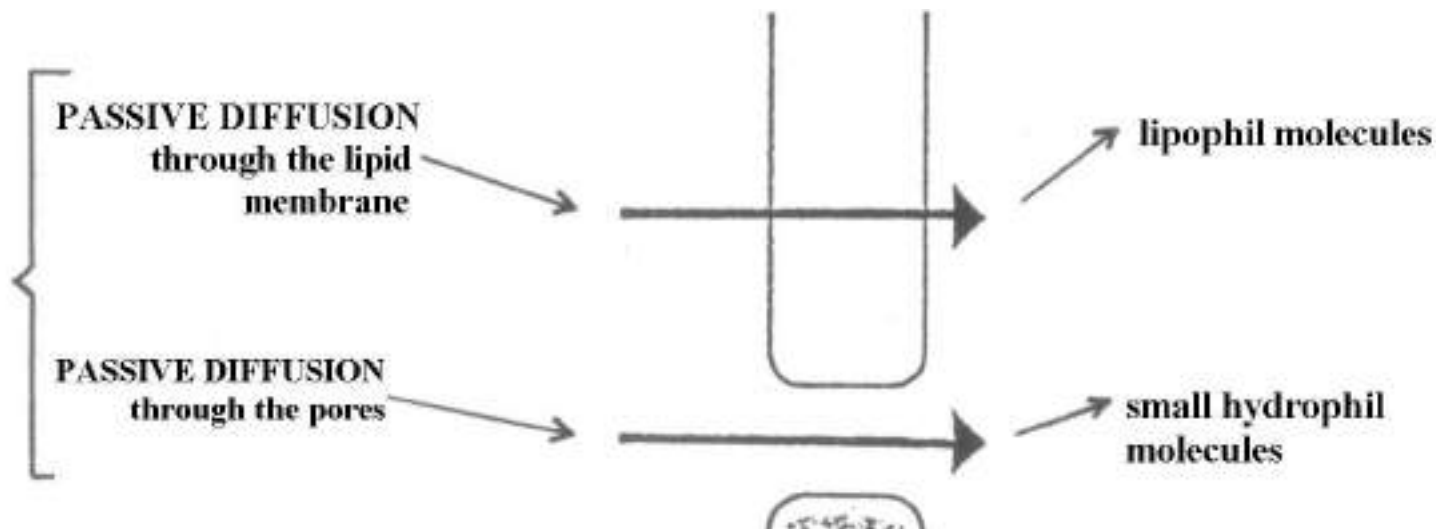

Transport across membrane

Passive diffusion

⇒ conditions

lipid soluble + non-ionized

⇒ energy source: concentration gradient

Transport across membrane

Active transport

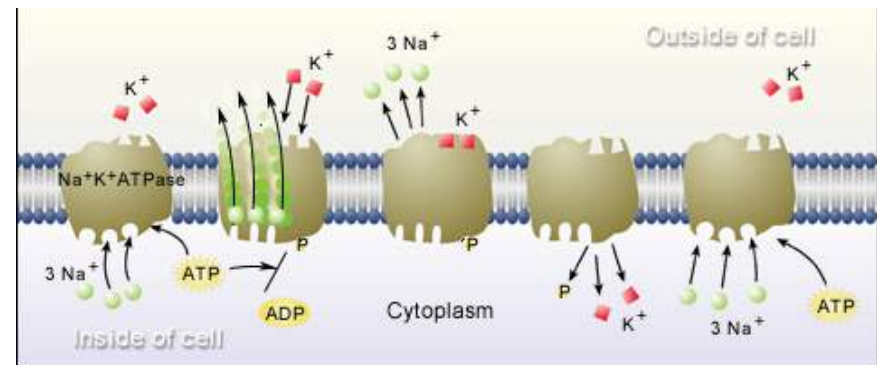

⇒ Energy demanding

- ♦ molecules move against the concentration gradient
- ♦ specific membrane carrier is required
- ♦ metabolic energy (ATP) is necessary
- ♦ may be inhibited by metabolic poison

⇒ nutrients

endogenous substances

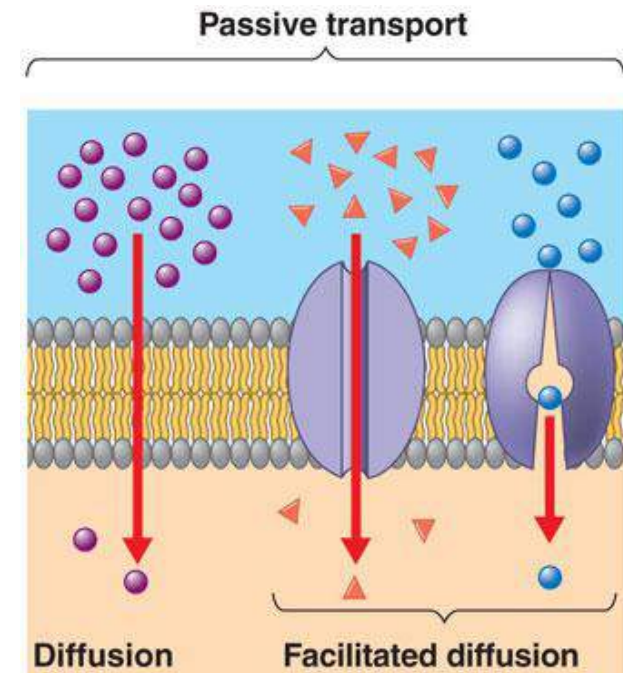

! but xenobiotics also
(lead)

Transport across membrane

Facilitated diffusion

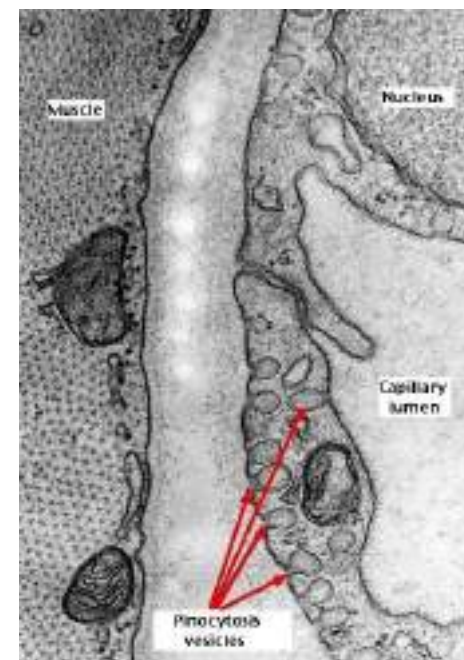

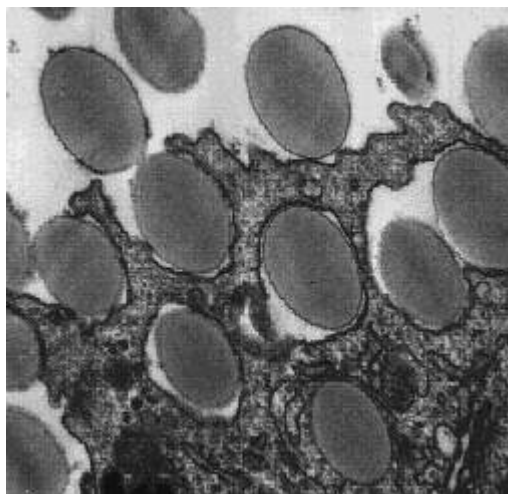

- ⇒ specific membrane carrier is required
- ⇒ metabolic energy \emptyset
- ⇒ energy source: concentration gradient

Transport across membrane

Phagocytosis („cell eating”)/Pinocytosis („cell drinking”)

- ⇒ phagocytosis results in the ingestion of particulate matter from the extracellular fluid
- ⇒ macromolecules/insoluble particles (asbestos)
- ⇒ invagination
- ⇒ energy source: metabolic energy

Specific membrane

⇒ **blood-brain-barrier (BBB)**

- the capillary endothelial cells of the CNS are tightly joined
- the capillaries of the CNS are largely surrounded by glial cells
- the protein concentration in the interstitial fluid of the CNS is much less than elsewhere in the body

⇒ **placental barrier**

⇒ **secretion epithelium (udder)**

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

The rate of transfer of chemical substances across cell membrane is dependent on their physico-chemical properties:

- ⇒ molecular size
- ⇒ lipid solubility (ethanol/water partition coefficient)
- ⇒ ionization
- ⇒ polarity/charge
- ⇒ similarity to endogenous substances

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Ionization

Many chemical substances exist in solution in both the ionized and nonionized form. The ionized form is often unable to penetrate the cell membrane because of its low lipid solubility.

The amount of a weak organic acid and base in the ionized form is dependent on its dissociation constant. The dissociation constant can be expressed as a pK_a → the pH at which an acid or base is 50% dissociated (nonionized=ionized).

The degree of dissociation and ionization of a weak acid or base is dependent on the pH of the medium. When the pH of a solution is equal to the pK_a of a compound, half the chemical exist in the ionized and half in the nonionized state.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Ionization

The degree of ionization of a chemical substance depends both on its pKa and on the pH of the solution in which it is dissolved, a relation described by the Henderson-Hasselbalch equations:

$$\text{For acids} \quad \text{pKa} - \text{pH} = \log \frac{[\text{nonionized}]}{[\text{ionized}]}$$

$$\text{For bases} \quad \text{pKa} - \text{pH} = \log \frac{[\text{ionized}]}{[\text{nonionized}]}$$

pH	Benzoic Acid	% Nonionized	Aniline	% Nonionized
1	<chem>OC(=O)c1ccccc1</chem>	99.9	<chem>[NH3+]c1ccccc1</chem>	0.1
2	<chem>OC(=O)c1ccccc1</chem>	99	<chem>[NH3+]c1ccccc1</chem>	1
3	<chem>OC(=O)c1ccccc1</chem>	90	<chem>[NH3+]c1ccccc1</chem>	10
4	<chem>OC(=O)c1ccccc1</chem>	50	<chem>[NH3+]c1ccccc1</chem>	50
5	<chem>[O-]C(=O)c1ccccc1</chem>	10	<chem>Nc1ccccc1</chem>	90
6	<chem>[O-]C(=O)c1ccccc1</chem>	1	<chem>Nc1ccccc1</chem>	99
7	<chem>[O-]C(=O)c1ccccc1</chem>	0.1	<chem>Nc1ccccc1</chem>	99

Figure 3-3. Effect of pH on the ionization of benzoic acid (pKa = 4) and aniline (pKa = 5).

As the pH decreases, more of the acid becomes nonionized → diffuse across membranes.

As the pH increases, more of the base becomes nonionized → diffuse across membranes.

PROCESSES OF TOXIKOKINETICS

- ⇒ ABSORPTION
- ⇒ DISTRIBUTION
- ⇒ METABOLISM
- ⇒ EXCRETION

TÁMOP-4.1.2.A/2-10/1-2010-0012

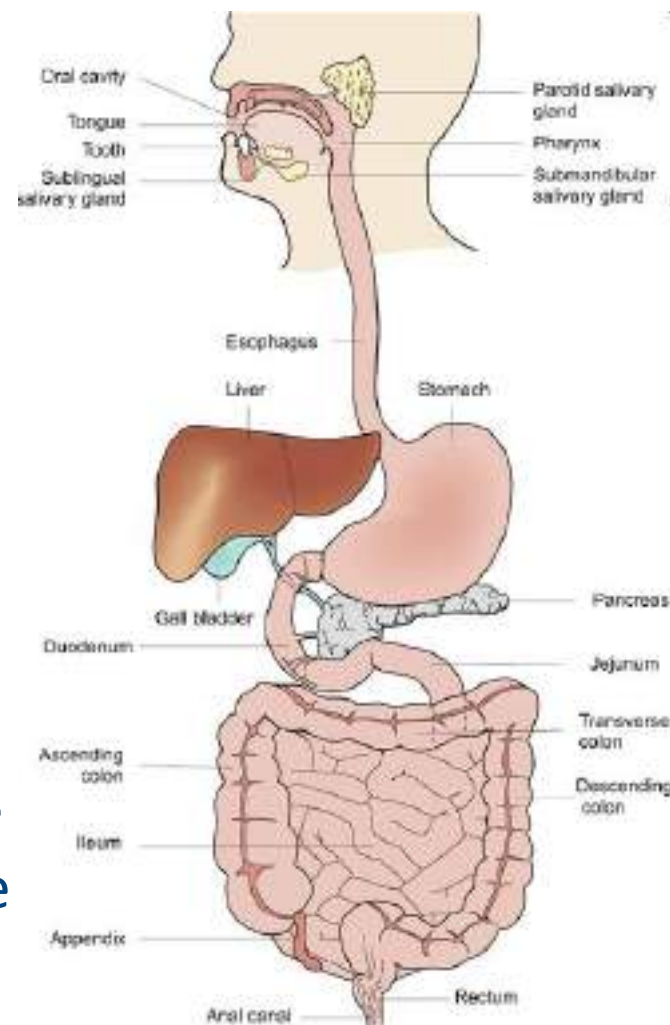

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ABSORPTION GASTROINTESTINAL TRACT

The GIT is one of the most important routes by which chemical substances are absorbed. Most chemical substances that are ingested by the oral route do not produce a systemic effect unless they are absorbed.

Absorption can occur at any point along the GIT.

Lipid soluble, non-ionized compounds can be absorbed along the whole length \Rightarrow passive diffusion.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ABSORPTION GASTROINTESTINAL TRACT

If a chemical substance is a weak organic acid or base, it will tend to be absorbed by diffusion in that part of the GIT in which it exist in the most lipid-soluble (nonionized) form.

Since gastric juice is acidic, and the intestinal contents are nearly neutral → the lipid solubility can differ markedly.

Weak organic acid → nonionized in the stomach → absorbed in the stomach

Weak organic acid → ionized in the intestine → hardly absorbed in the intestine

FOR WEAK ACIDS	
$pK_a - pH = \log \frac{[\text{nonionized}]}{[\text{ionized}]}$	
Benzoic acid $pK_a \approx 4$	
Stomach $pH \approx 2$	
$4 - 2 = \log \frac{[\text{nonionized}]}{[\text{ionized}]}$	
$2 = \log \frac{[\text{nonionized}]}{[\text{ionized}]}$	
$10^2 = \frac{[\text{nonionized}]}{[\text{ionized}]}$	
$100 = \frac{[\text{nonionized}]}{[\text{ionized}]}$	
Ratio favors absorption	
Intestine $pH \approx 6$	
$4 - 6 = \log \frac{[\text{nonionized}]}{[\text{ionized}]}$	
$-2 = \log \frac{[\text{nonionized}]}{[\text{ionized}]}$	
$10^{-2} = \frac{[\text{nonionized}]}{[\text{ionized}]}$	
$\frac{1}{100} = \frac{[\text{nonionized}]}{[\text{ionized}]}$	
Ratio favors absorption	
FOR WEAK BASES	
$pK_b - pH = \log \frac{[\text{ionized}]}{[\text{nonionized}]}$	
Aniline $pK_b \approx 5$	
Stomach $pH \approx 2$	
$5 - 2 = \log \frac{[\text{ionized}]}{[\text{nonionized}]}$	
$3 = \log \frac{[\text{ionized}]}{[\text{nonionized}]}$	
$10^3 = \frac{[\text{ionized}]}{[\text{nonionized}]}$	
$1000 = \frac{[\text{ionized}]}{[\text{nonionized}]}$	
Ratio favors absorption	
Intestine $pH \approx 6$	
$5 - 6 = \log \frac{[\text{ionized}]}{[\text{nonionized}]}$	
$-1 = \log \frac{[\text{ionized}]}{[\text{nonionized}]}$	
$10^{-1} = \frac{[\text{ionized}]}{[\text{nonionized}]}$	
$\frac{1}{10} = \frac{[\text{ionized}]}{[\text{nonionized}]}$	
Ratio favors absorption	

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ABSORPTION GASTROINTESTINAL TRACT

- ⇒ water soluble, small molecules ⇒ filtration
- ⇒ water soluble, macromolecules ⇒ carrier-mediated

INFLUENCING FACTORS

- ⇒ the chemical substance may be altered by the acid, enzymes, or intestinal flora to form a new compound that may differ in toxicity from the parent compound (e.g. snake venom)
 - ⇒ alteration of GIT motility can affect the absorption of chemical substances (decreased motility → increase the overall absorption)
 - ⇒ food (one metal can alter the absorption of another)
e.g. $\text{Cd} \rightarrow \text{Zn}$, Cu ; $\text{Zn} \rightarrow \text{Cu}$, $\text{Mg} \rightarrow \text{F}$; milk $\rightarrow \text{Pb}$

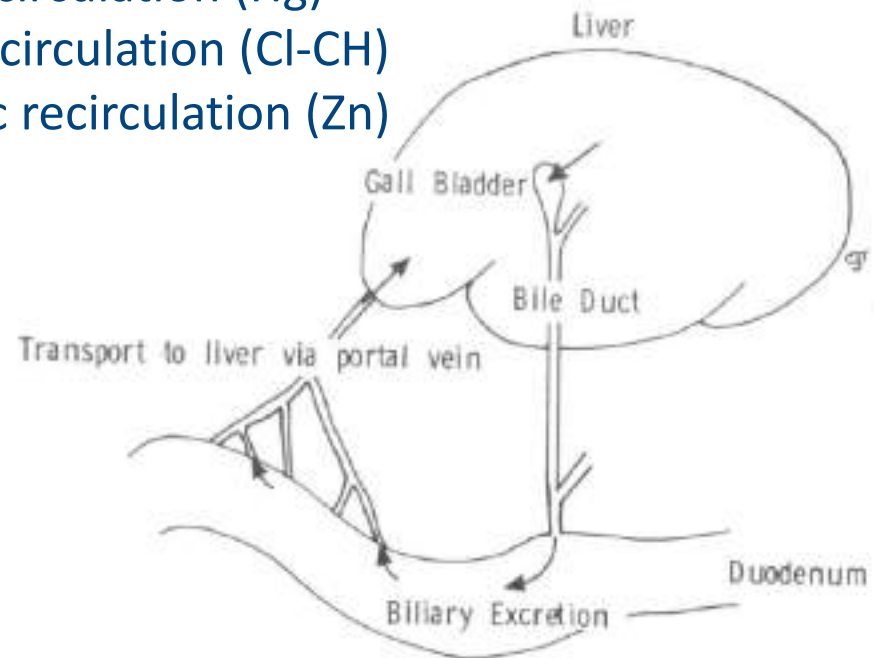

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ABSORPTION GASTROINTESTINAL TRACT

EXCRETION + RE-ABSORPTION ⇔ RECIRCULATION

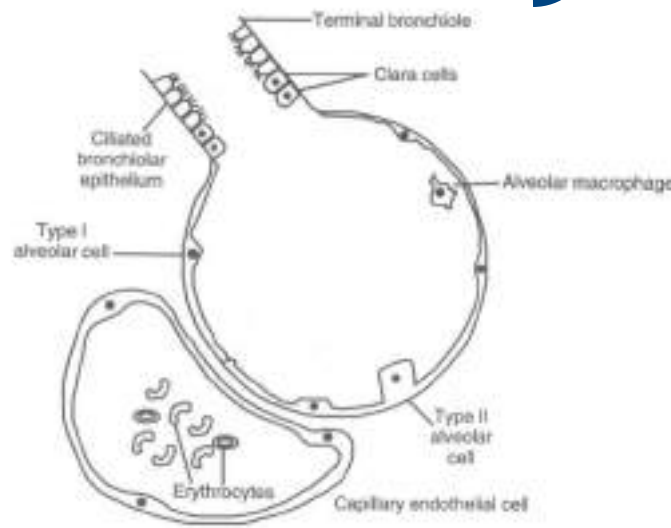

- ⇒ gastro-salivaris recirculation (Hg)
- ⇒ entero-hepatic recirculation (Cl-CH)
- ⇒ entero-pancreatic recirculation (Zn)

ABSORPTION LUNG - AIRWAYS

- ⇒ large surface area (50-100 m²)
- ⇒ excellent blood supply
- ⇒ thin barrier

} rapid absorption

ABSORPTION

LUNG - AIRWAYS

⇒ gases, vapours, volatile liquids, aerosols

the rate of absorption of gases is variable and dependent on the chemical substance's blood:gas solubility

liquid aerosol, if lipid-soluble, will readily cross the alveolar cell membranes by passive diffusion

⇒ solid particles (smoke, powder)

depends on size

$< 1 \mu\text{m}$ ⇒ absorb into blood

$> 1 \mu\text{m}$ ⇒ phagocytosis

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

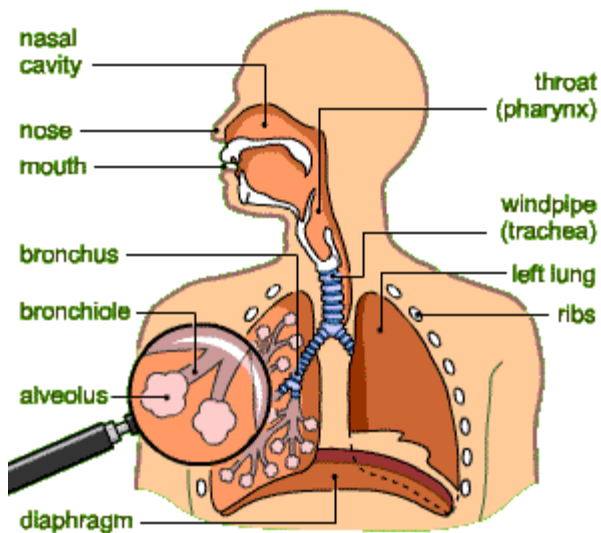

Image src: <http://www.bbc.co.uk/schools/gcsebitesize/img/pe01021.gif>

Nasopharyngeal Region

5-30 μm

Trachea

Bronchi

Bronchioles

1-5 μm

The alveolar region is an area of the lung where chemical substances readily absorbed

Alveolar Region

1 μm

ABSORPTION SKIN

The skin is a relatively good lipoid barrier separating humans or animals from their environment.

Some chemical substances can be absorbed through the skin in sufficient quantities to produce systemic effect.
(e.g. nerve gases → Sarin).

In order to be absorbed through the skin, a chemical substance must cross several cell layers to reach blood vessels.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ABSORPTION SKIN

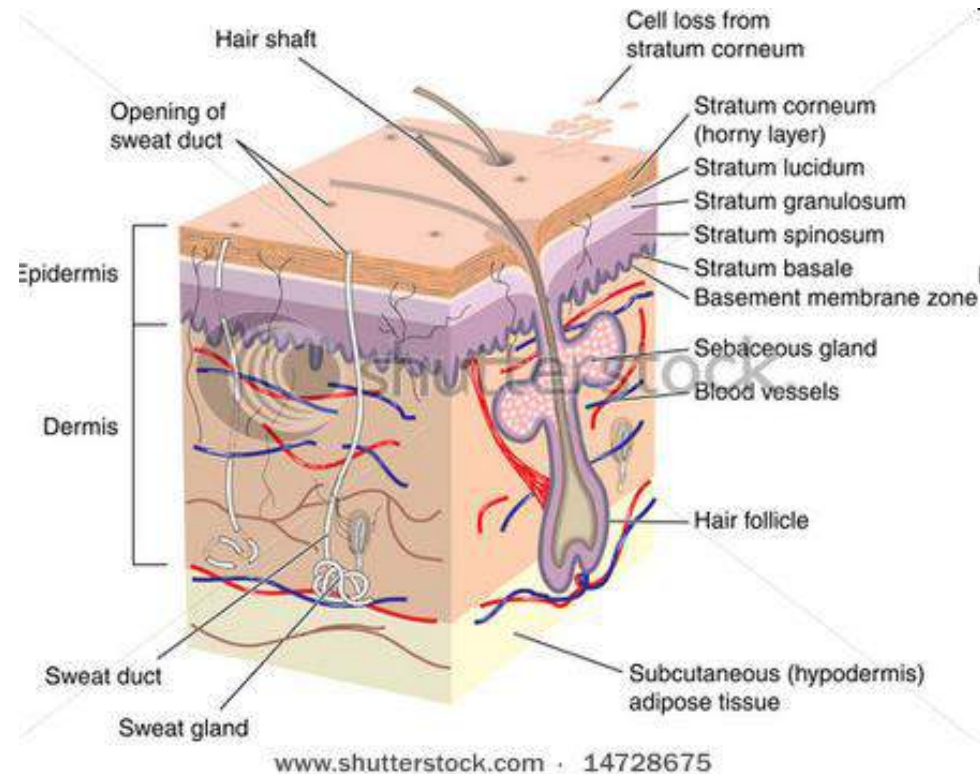

Phases of skin absorption:

⇒ through the epidermis (rate-limiting barrier)

stratum corneum (thin, keratin-filled, dried cell layer → dead surface layer)

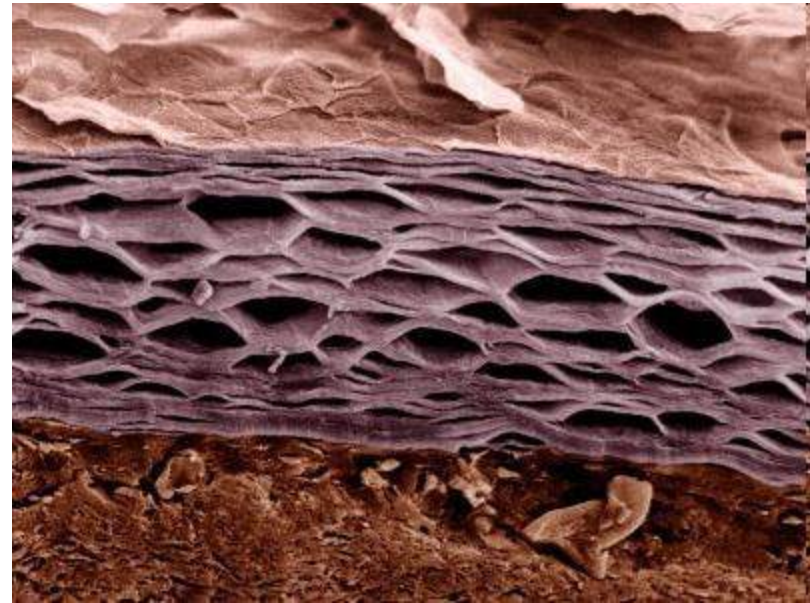

⇒ mainly lipid soluble substances can cross

⇒ through the dermis (porous, watery diffusion medium)

ABSORPTION SKIN

- The stratum corneum plays a critical role in determining cutaneous permeability.
 - ⇒ intact
absorption limited
 - ⇒ injured
increase permeability
- Hydration of skin
 - ⇒ the water increases the permeability of the stratum corneum
- Site (thick on the palm and sole 400-600 μm
thin on the arms, back, legs, abdomen 8-15 μm)

DISTRIBUTION

Movement of chemical substance from the systemic circulation (blood) to peripheral compartments (tissues) where the chemical substance is present.

Distribution of a chemical substance from systemic circulation to tissues is dependent on the ability of the chemical substance to pass through the cell membrane of the various tissue (lipid solubility, ionization, molecular size), binding to plasma proteins, rate of blood flow and special barriers.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

DISTRIBUTION

BLOOD - BINDING

Chemical substances are present in blood in:

Free form: active, diffusible, available for biotransformation and excretion.

Bound form: inert, non-diffusible, not available for metabolism, excretion and entering the target organ to produce injury.

- **erythrocyte** (Pb, organic Hg)
 - ⇒ adsorption on surface
 - ⇒ binding to component (Hb – CO)
- **plasma proteins**
 - ⇒ albumin (inorganic Hg, aromatic CH
Ca, Zn, Cd, I, Br)
 - ⇒ globulin (small molecule: Cu, Zn, Fe)
+ lipid soluble substance

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

DISTRIBUTION

BLOOD - BINDING

➤ CONSEQUENCES

⇒ cc. of free molecule ↓

⇒ rate of tissue distribution ↓

⇒ rate of excretion ↓

⇒ time of onset ↑

⇒ saturation of binding capacity may occur

⇒ cc. of free molecules ↑

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

TISSUE DISTRIBUTION

⇒ across capillaries, membranes
by transport mechanisms
passive diffusion
specific transport systems (active
transport)
phagocytosis-pinocytosis

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

TISSUE BINDING STORAGE

Selective distribution.

Chemical substances are often concentrated in a specific tissue.

⇒ Pb	⇒ RBC, liver, bone
⇒ F	⇒ bone, tooth
⇒ Cu	⇒ liver
⇒ As	⇒ hair, bone
⇒ Se	⇒ horny matter
⇒ Cl-CH	⇒ fat tissue

CONSEQUENCES

⇒ toxicity ↓ (protectiv mechanism)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

REDISTRIBUTION - ACCUMULATION

The distribution of a chemical substance in the body can change with time.

⇒ Pb ⇒ RBC, liver (immediately after absorption)

⇒ Pb ⇒ bone (90% a month after administration)

⇒ highly lipophilic chemicals ⇒ brain (well-perfused tissue)

⇒ highly lipophilic chemicals ⇒ fat (less well-perfused tissue)

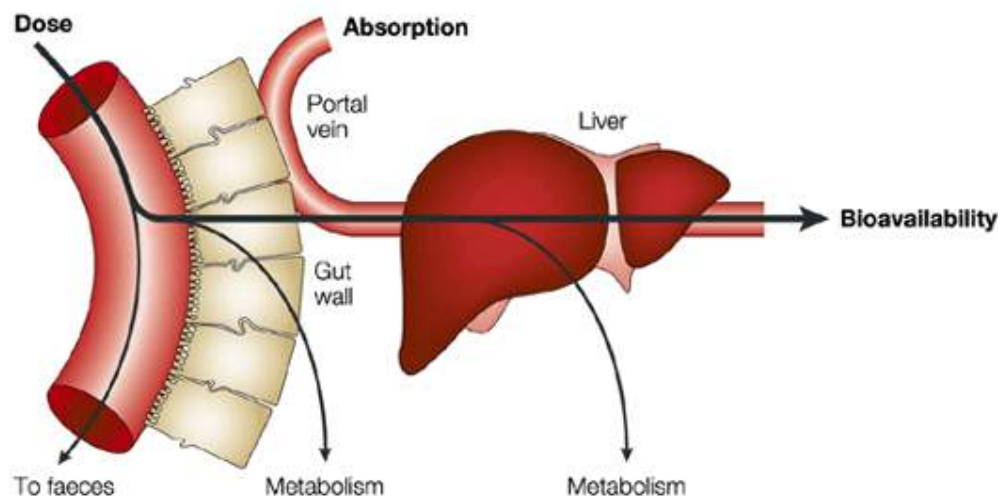

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

FIRST PASS EFFECT

After oral absorption of a chemical substance before entering the general blood circulation, it can be biotransformed by the gastrointestinal cells and the liver.

Nature Reviews | Drug Discovery

Metabolism = biotransformation

The conversion of a chemical substance from one form to another by the actions of organisms or enzymes.

The chemical structure and physicochemical properties of chemical substances are changed by the enzymatic metabolism.

Biotransformations occur between absorption and elimination from kidneys.

In general, enzymatic metabolism: transforms lipophilic parent chemical substances to more hydrophilic metabolites, which can be readily excreted into bile or urine.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Biotransformation can also result in bioactivation, which involves the production of reactive metabolites that are more toxic, mutagenic, or carcinogenic than their parent compound(s).

Chemical substances may be converted to:

- less toxic metabolites
- more toxic metabolites
- metabolites with different type of effect or toxicity

The body metabolises not only exogenous (foreign) substances but endogenous (internally created) substances too.

Metabolism in the body can be divided into two different types of reactions: Phase I reactions and Phase II reactions.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Toxicokinetics

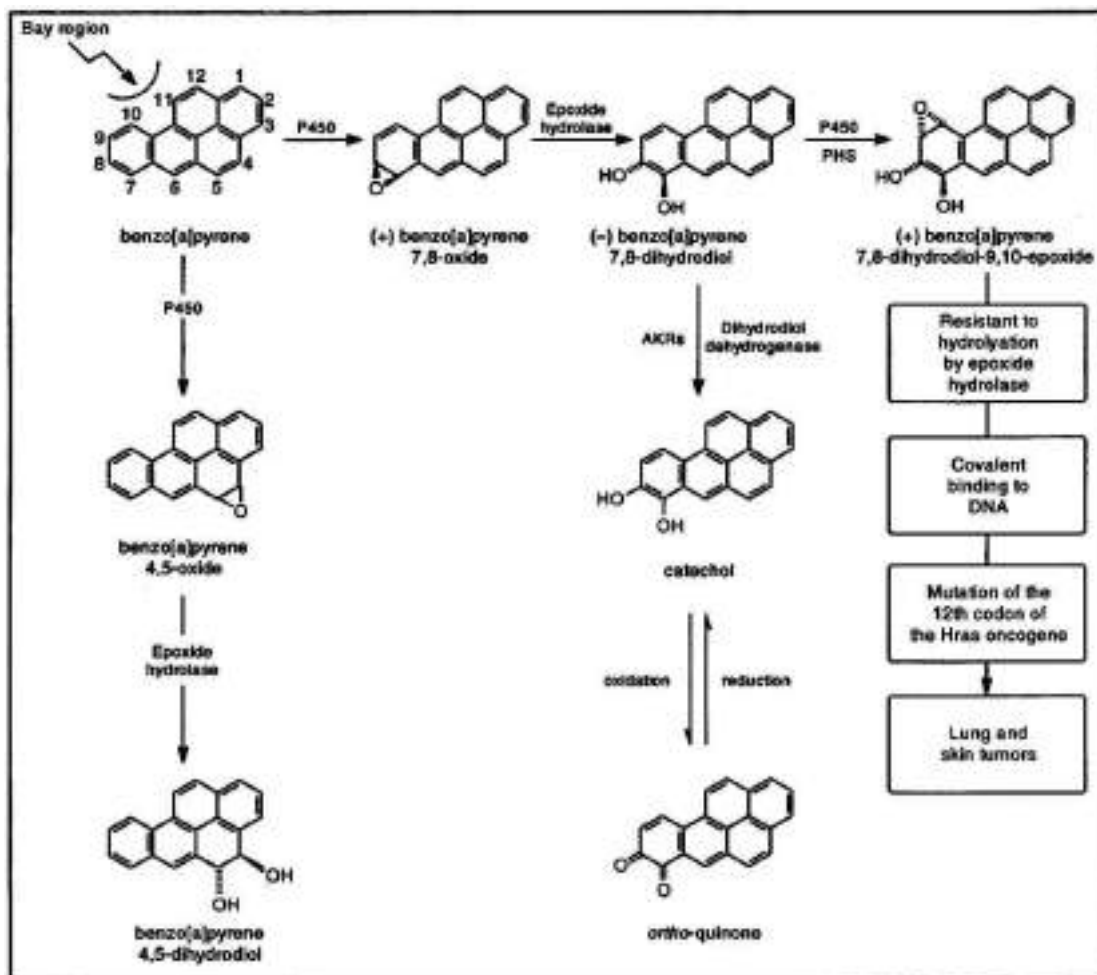

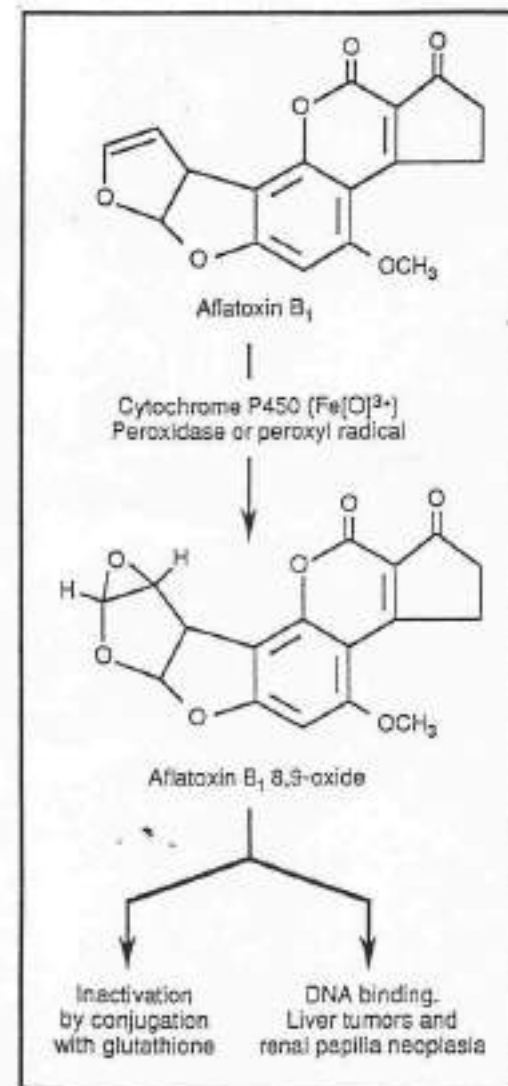

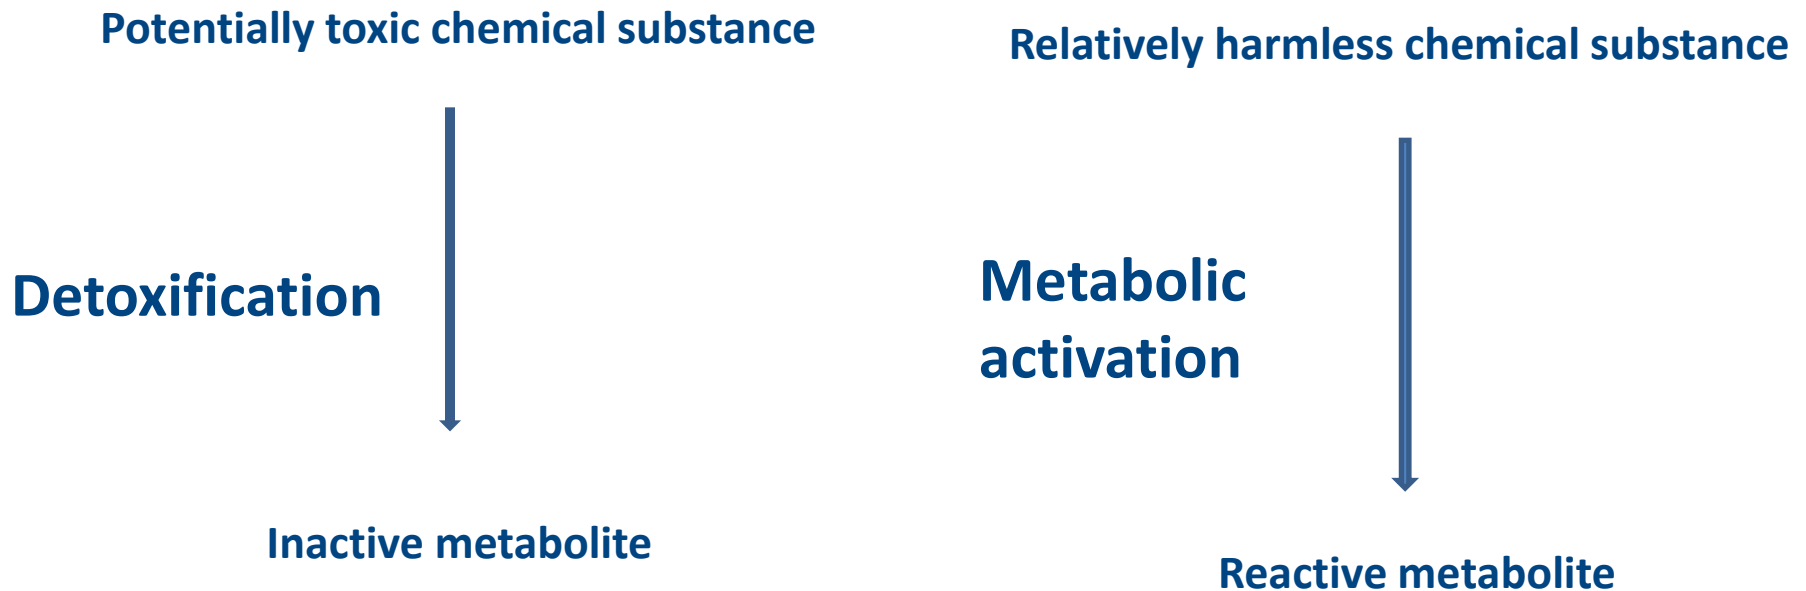

Figure 6-6. Role of epoxide hydrolase in the inactivation of benzo[a]pyrene 4,5-oxide and in the conversion of benzo[a]pyrene to its tumorigenic bay-region diolepoxide.

METABOLISM

Phase I reactions: introduces or uncovers polar functional groups that provide sites for Phase II metabolism.

Major classes of reaction:

- oxidation
- reduction
- hydrolysis

Principal Phase I enzymes:

- Cytochrome P450 enzymes
- Flavin monooxygenases
- Monoamine oxidases
- Esterases
- Amidases
- Hydrolases
- Reductases, dehydrogenases, oxidases

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

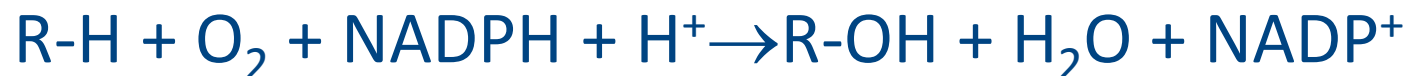

Cytochrome P450 enzymes

The most important metabolizing enzyme for chemical substances.

Reaction type is mainly oxidation in the presence of oxygen or reduction under low oxygen tension.

Located in the smooth endoplasmic reticulum of all major organs and tissues (especially liver, intestine, kidney, skin, brain).

Overall reaction

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Cytochrome P450 enzymes

Substrate specificity is very low.

Attributes

- Genetic Polymorphism
- Enzyme Induction
- Enzyme Inhibition

Multiple CYP gene families have been identified in humans, and the categories are based upon protein sequence homology.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Polymorphic enzymes

Cytochrome P450 Enzymes:

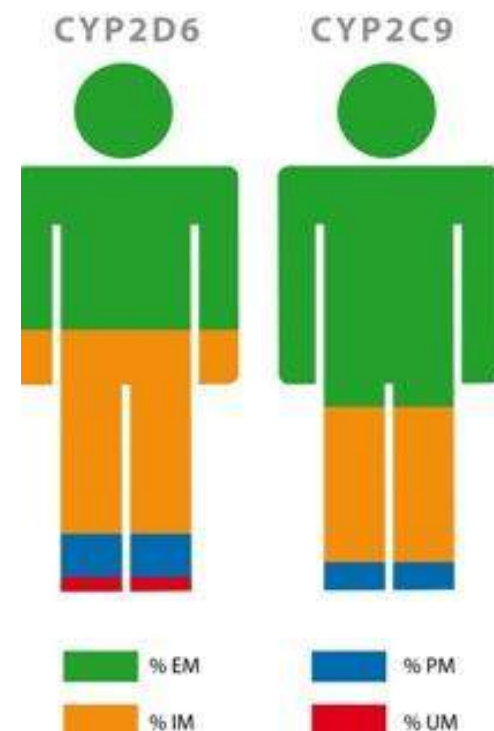

- CYP 2D6
- CYP 2C19
- CYP 2C9

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

- **CYP 2D6 in Caucasians:**
 - PM: 7%
 - IM: 40%
 - EM: 50% (normal metabolizers)
 - UM: 3%
- **CYP 2C19 in Caucasians:**
 - PM: 3%
 - IM: 27%
 - EM: 70% (normal metabolizers)

Kirchheiner J, Nickchen K, Bauer M, et al. Mol Psychiatry 2004 May; 9 (5):442-73.

CYP1A1

- Metabolizes PAHs
- PAH-inducible
- Ubiquitous
- Expressed in utero, even 12-h ovum

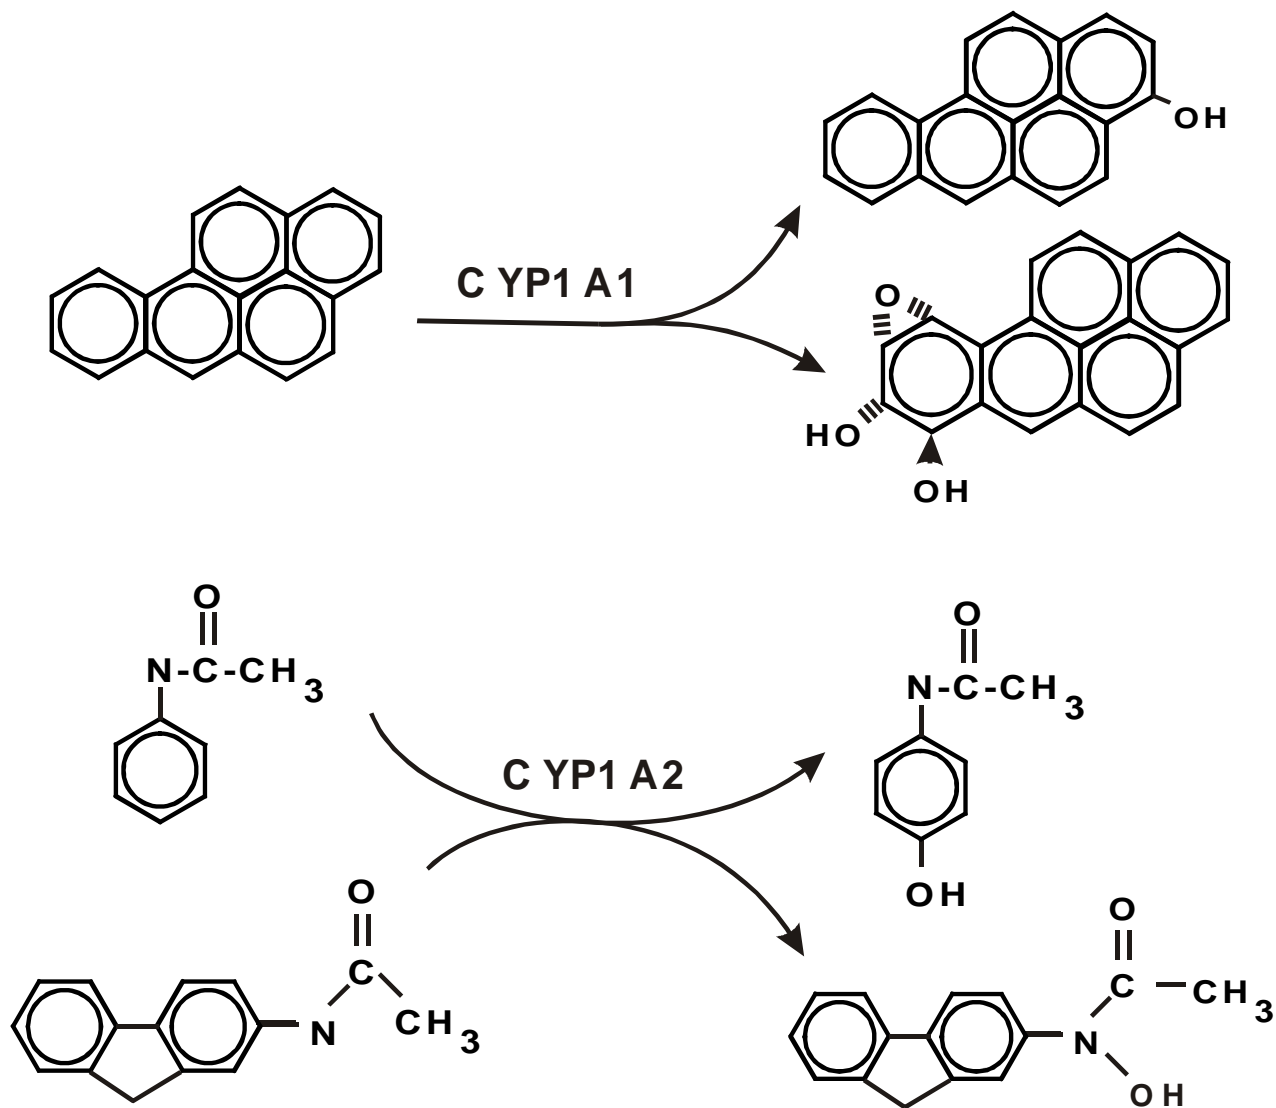

CYP1A2

- Metabolizes aryl and alkyl amines
- PAH-inducible
- Not detectable until neonatal period

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

General rule of big pharma

Any candidate drug that shows inducibility of CYP1A1/1A2/1B1 is regarded as hazardous, potentially **cancer-causing**.

Such candidate drugs — usually **abandoned immediately**, without further cost to the company.

TÁMOP-4.1.2.A/2-10/1-2010-0012

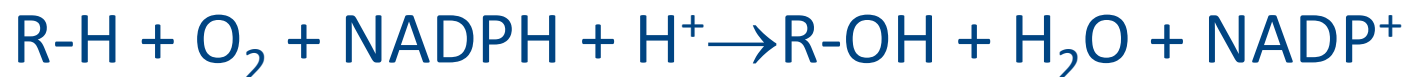

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Flavin monooxygenases

- Flavoprotein
- Mixed-function amine oxidase
- Located in smooth endoplasmic reticulum in human, rabbit liver, guinea-pig lung, human kidney
- Uses NADPH as a source of reducing equivalents
- Not inducible

Overall reaction

TÁMOP-4.1.2.A/2-10/1-2010-0012

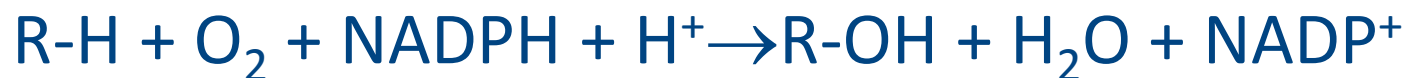

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Monoamine oxidases

- Metabolizes endogenous monoamine neurotransmitters
- Found in the endoplasmic reticulum and in mitochondria, of nerve endings and liver
- Uses NADPH as a source of reducing equivalents

Overall reaction

TÁMOP-4.1.2.A/2-10/1-2010-0012

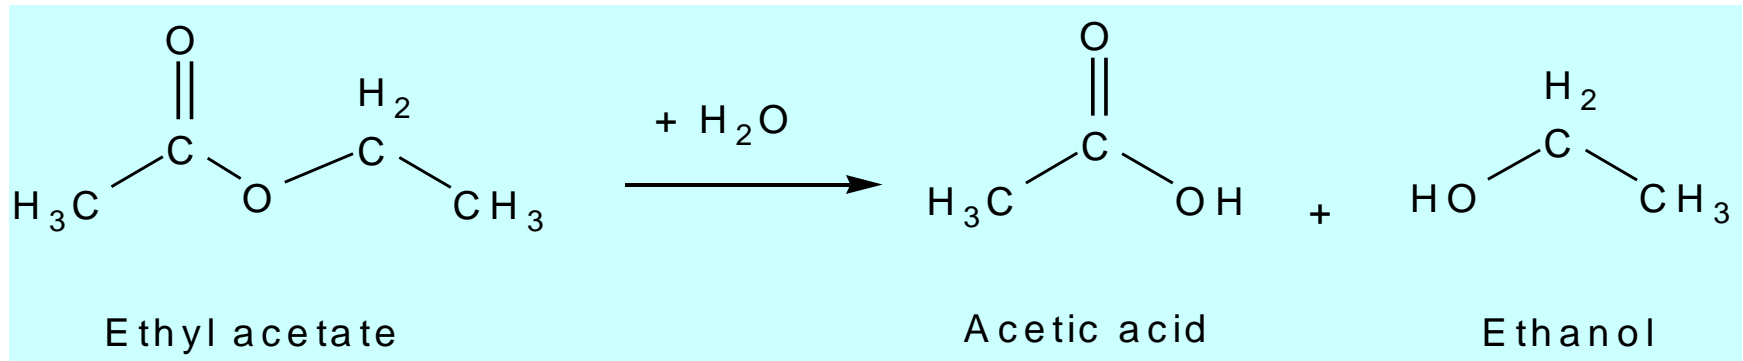

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Esterases

Hydrolyse esters to carboxylic acid and alcohol functional groups.

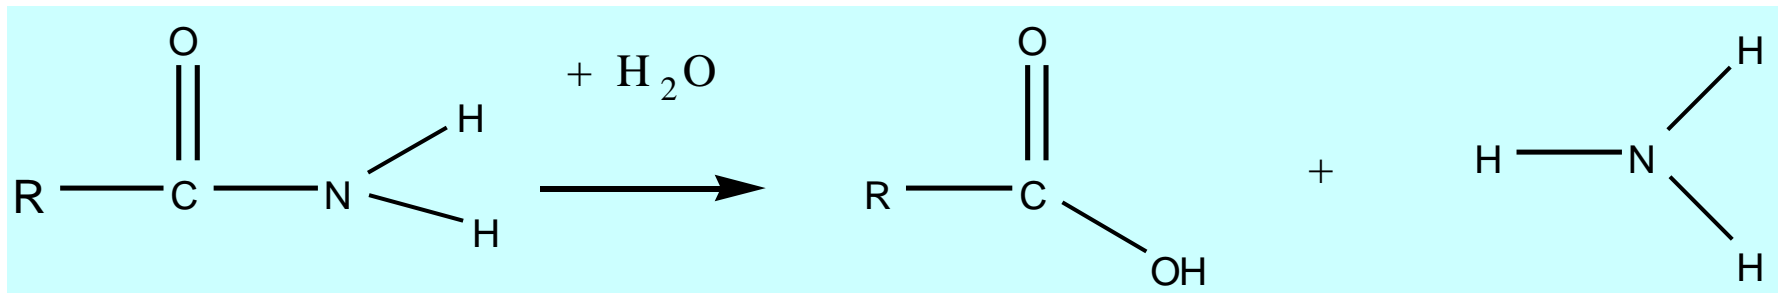

Non-specific esterases in plasma, more substrate-specific forms in liver cytosol.

Amidases

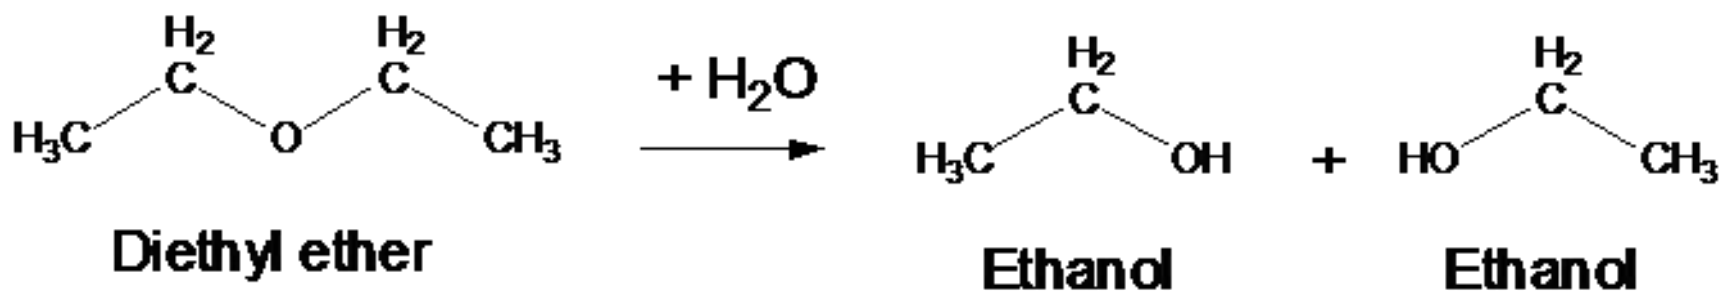

Hydrolyse amides to carboxylic acids and amines (or ammonia).

Found in plasma and in liver cytosol.

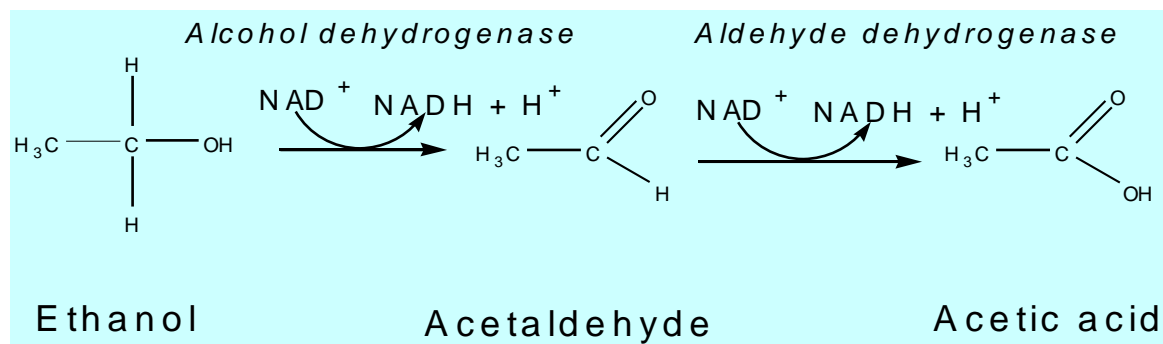

Hydrolases

Hydrolyse ethers.

Reductases, dehydrogenases, oxidases

Found in cytosol, endoplasmic reticulum, mitochondria.

METABOLISM

Phase II reactions

Functional group or metabolite formed by phase I is masked by conjugation with natural endogenous constituent as glucuronic acid, glutathione, sulphate, acetic acid, glycine or methyl group.

These reactions usually result in chemical substance inactivation with few exceptions e.g. morphine-6-conjugate is active.

Phase II reactions usually occur after Phase I but can also take place earlier than Phase I.

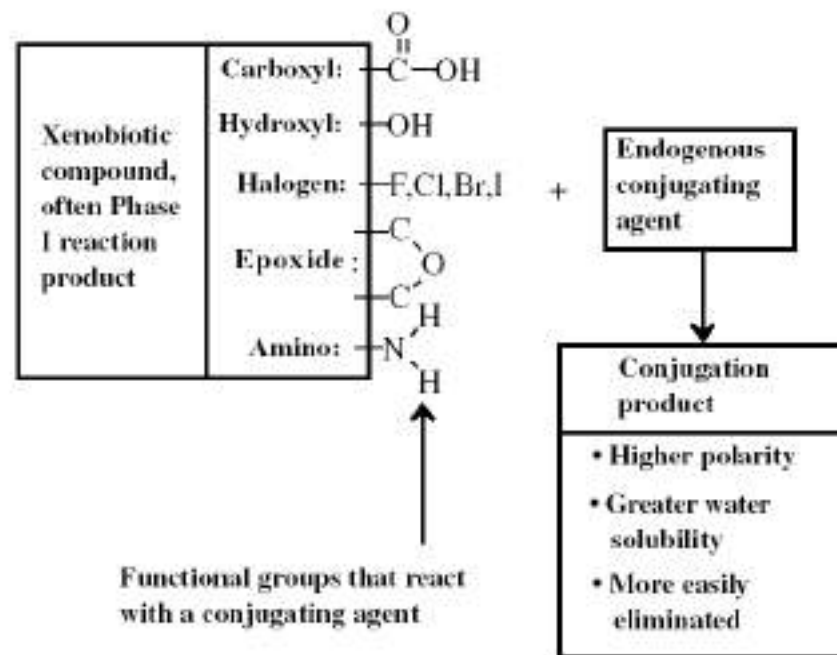

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Phase II Metabolism requires the presence of a reactive group:

- Hydroxyl group (R-OH)
- Amino group (R-NH₂)
- Carboxyl group (R-COOH)
- Epoxide group (R₁-COC-R₂)
- Thiol group (R-SH)
- Halogen group (R-X)
- Electrophiles
- Some others

Toxicokinetics

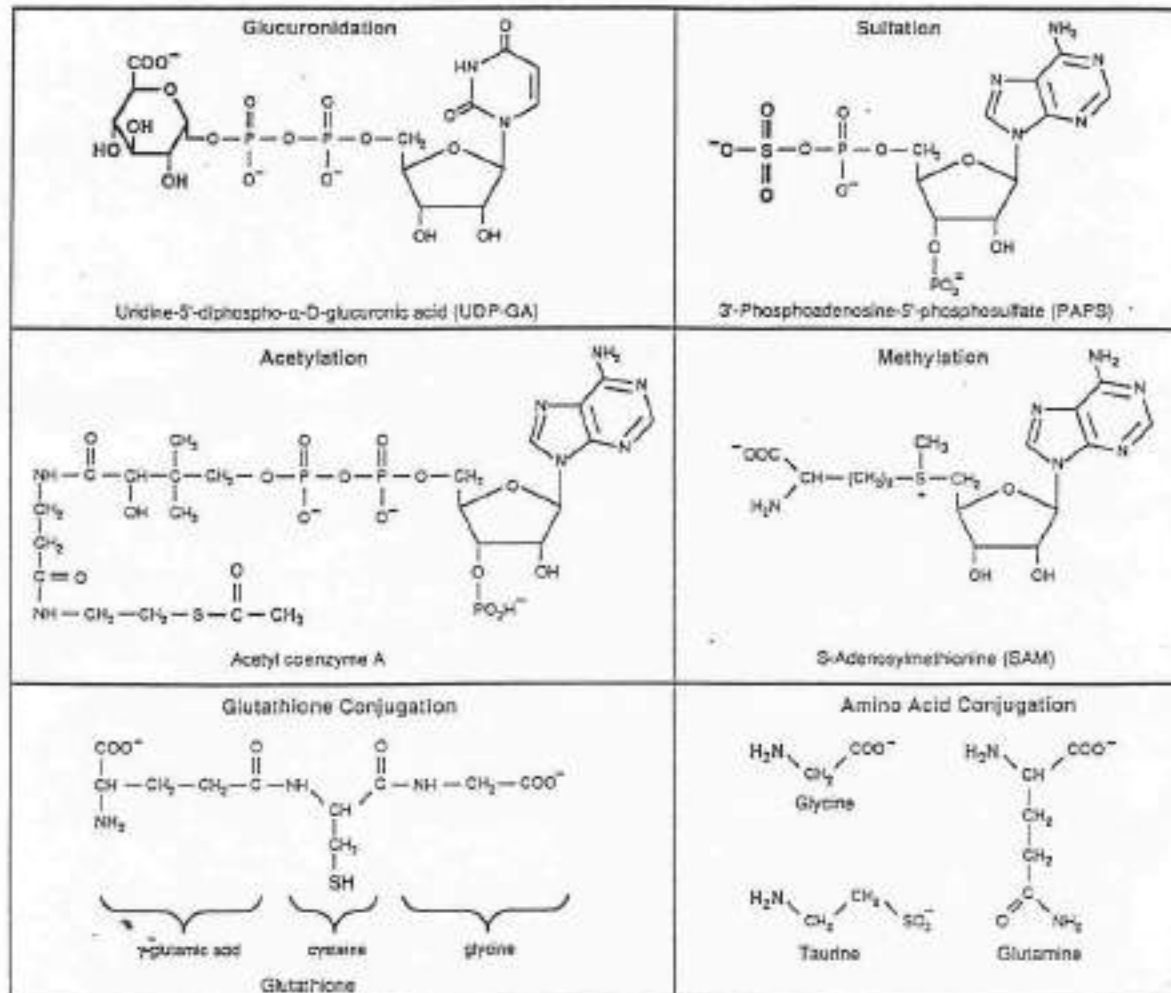

Figure 6-41. Structures of cofactors for phase II biotransformation.

The functional group that reacts with or is transferred to the xenobiotics is shown in bold.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Conjugation by Glucuronides

Most common endogenous conjugating agents in the body react with xenobiotics through the action of uridine diphosphate glucuronic acid (UDPGA - cofactor).

Group transferred glucuronic acid.

Transfer is mediated by UDP glucuronosyl transferase enzymes.

Found in microsomes in liver, kidney, intestine.

In liver, conjugated metabolites typically excreted into bile.

Cats are deficient in glucuronosyl transferase.

Bilirubin is an endogenous substrate.

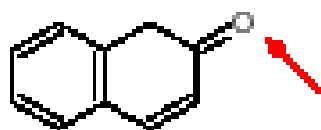

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Glucuronosyl Transferase Substrates

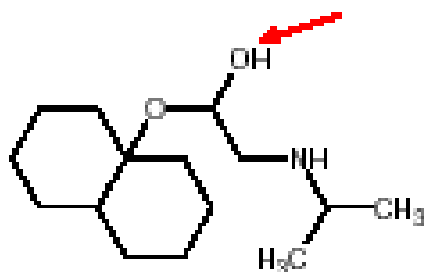

Coumarin

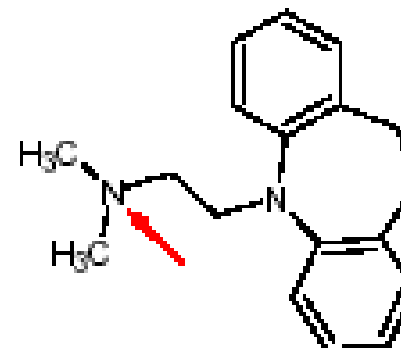

2-Naphthylamine

Thiophenol

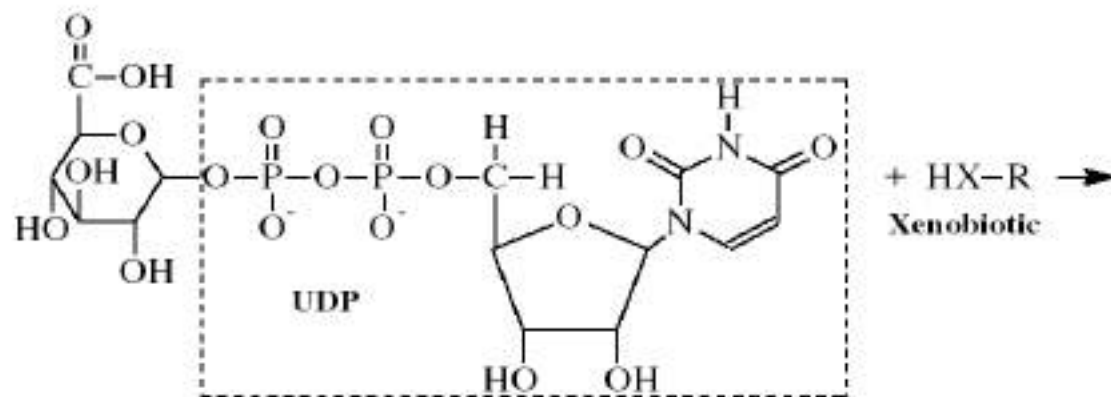

Propanolol

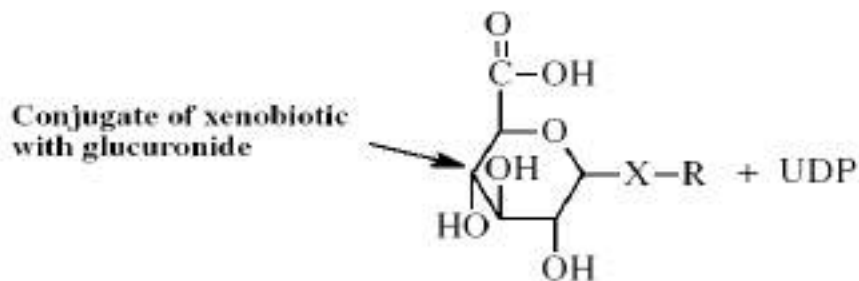

Imipramine

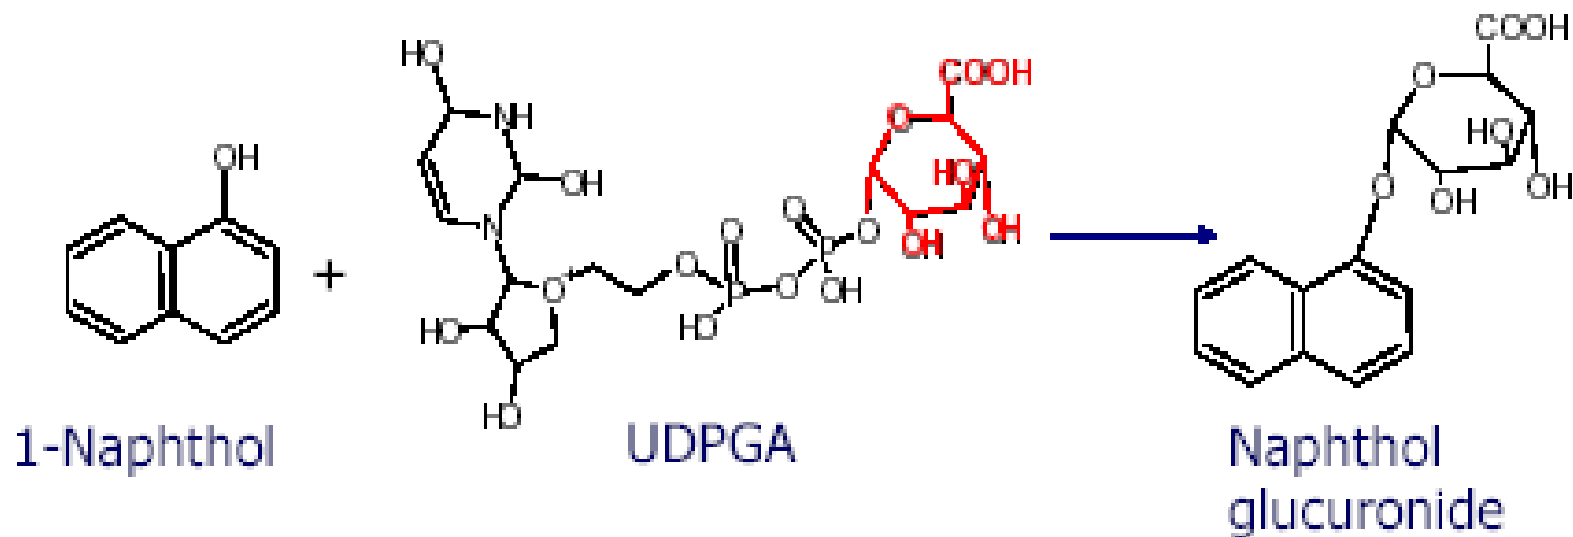

Conjugation by Glucuronides

Uridine-5'-diphospho- α -D-glucuronic acid, UDPGA

UDPG transferase reaction sequence

Conjugation by Glutathione

Group transferred glutathione.

Cofactor glutathione (tripeptide - glycine, glutamic acid, cysteine).

Transfer is mediated by glutathione S-transferase enzymes.

Primarily cytosolic dimeric proteins found in liver, some microsomal.

Conjugates with a wide variety of xenobiotic species, including alkenes, alkyl epoxides (1,2-epoxyethylbenzene), arylepoxides (1,2-epoxynaphthalene), aromatic hydrocarbons, aromatic halides, alkyl halides (methyl iodide), and aromatic nitro compounds.

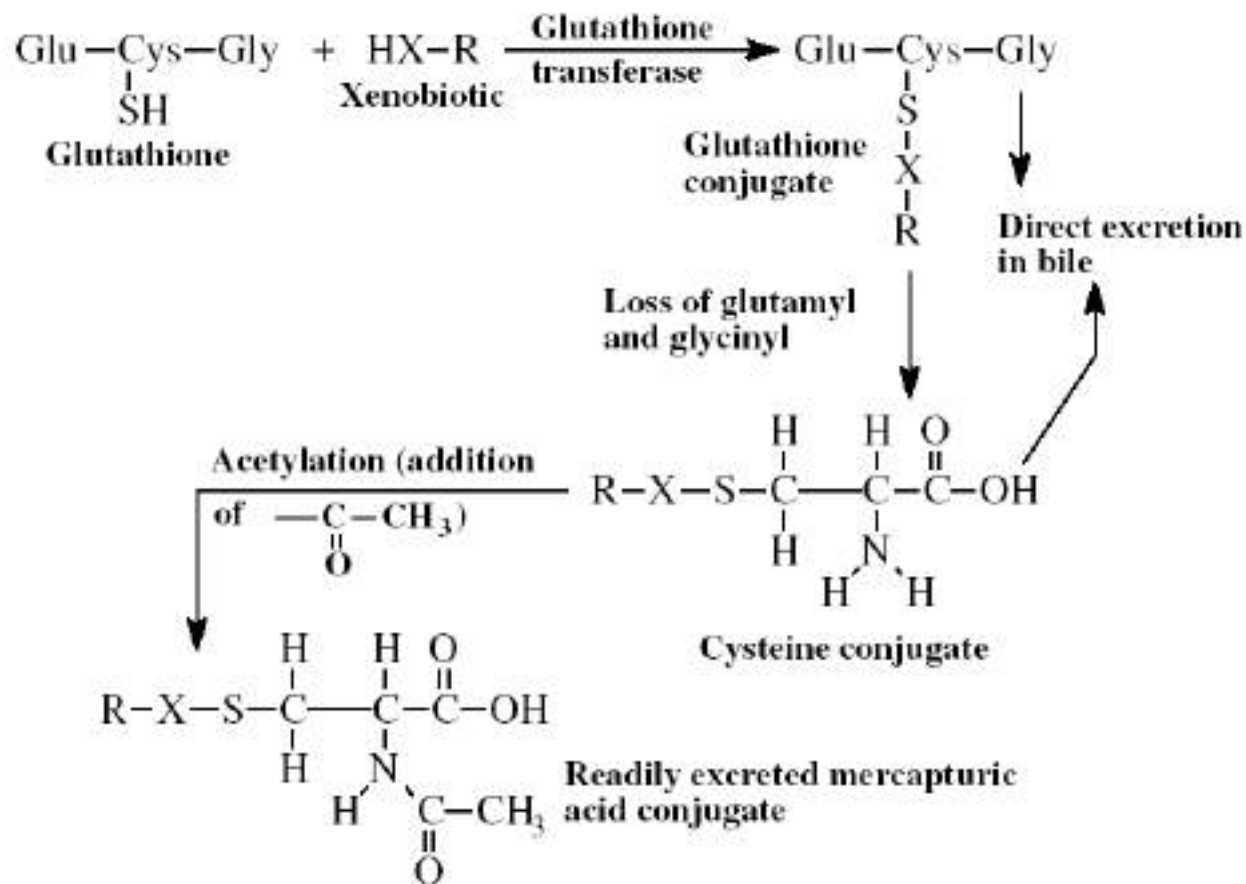

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

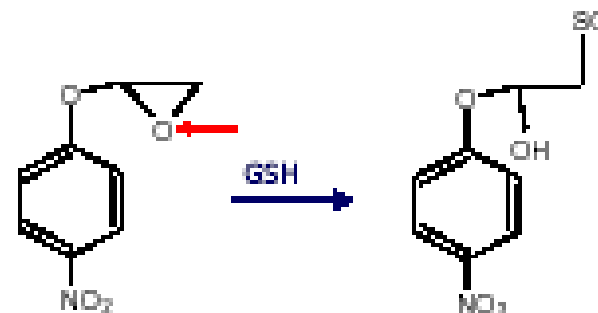

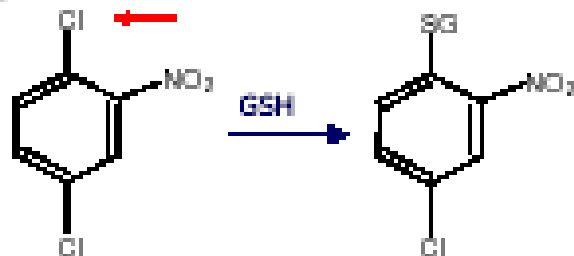

Conjugation by Glutathione

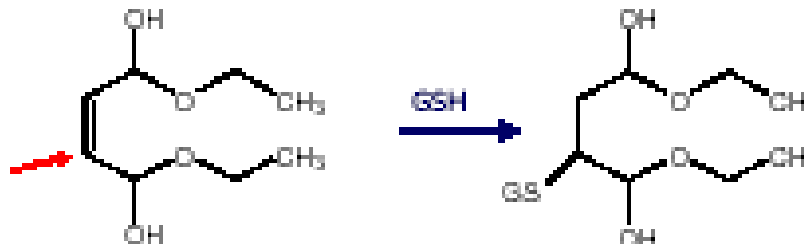

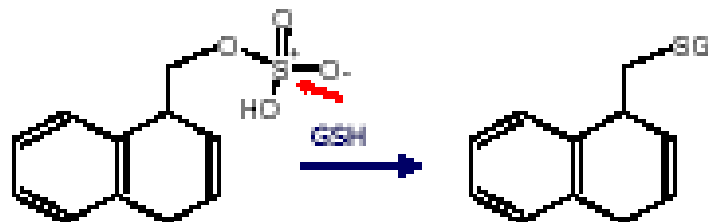

Examples of Glutathione S-Transferase Substrates

1-chloro-2,4 dinitrobenzene

1,2 epoxy-3-(p-nitrophenoxy)propane

1-methylnaphthalene methyl sulfate

diethyl maleate

Conjugation by Sulfate

Group transferred sulfate.

Cofactor PAPS (3'-phosphoadenosine-5'-phosphosulfate).

Types of substrate: phenols, alcohols, aromatic amines.

Transfer is mediated by sulfotransferase enzymes (primary cytosol).

Toxic sulfate conjugate (the sulfate conjugate of N-hydroxyacetyl-aminofluorene is thought to be the proximate carcinogen in the case of this compound).

Pigs and opossums are deficient in sulfate conjugation.

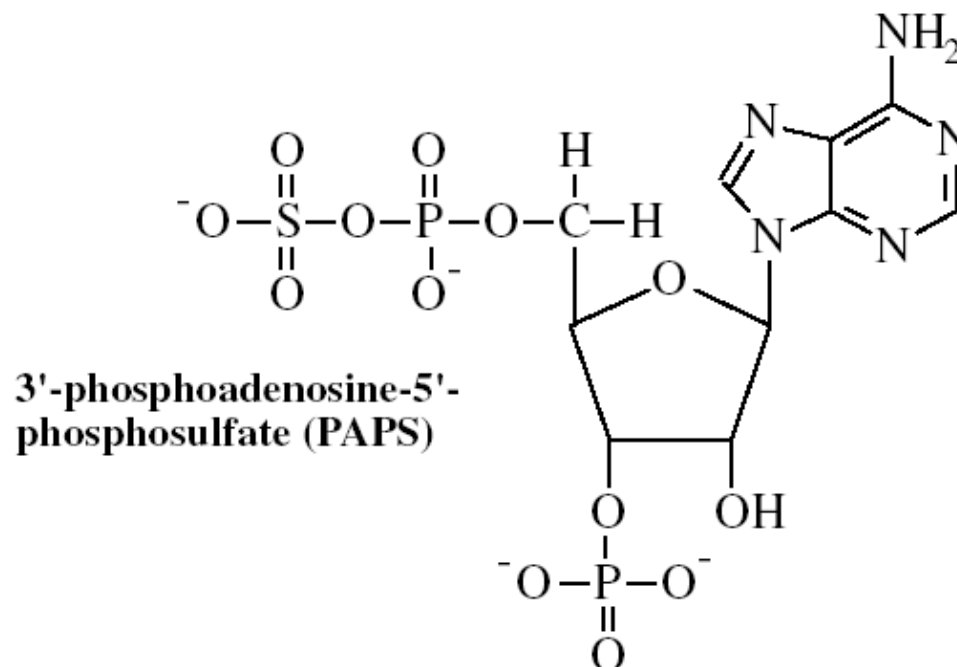

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Conjugation by Sulfate

Structure of PAPS

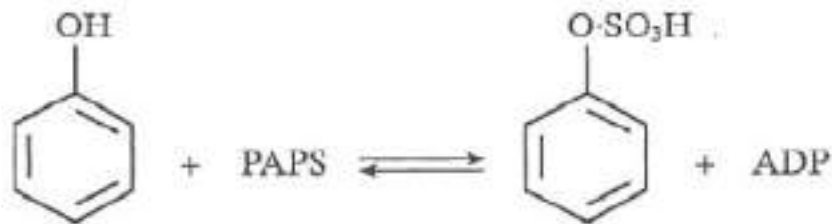

Conjugation by Sulfate

TABLE 6.3 Examples of Sulfate Conjugation to Alcohols, Phenols, and Aromatic Amines.

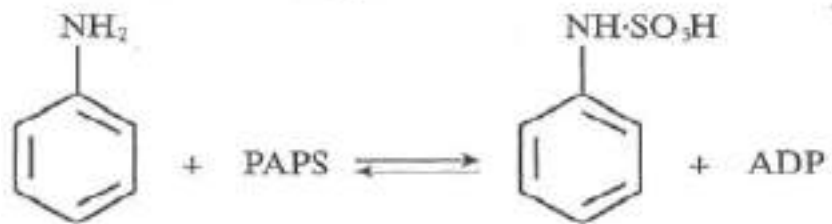

Alcohol conjugation

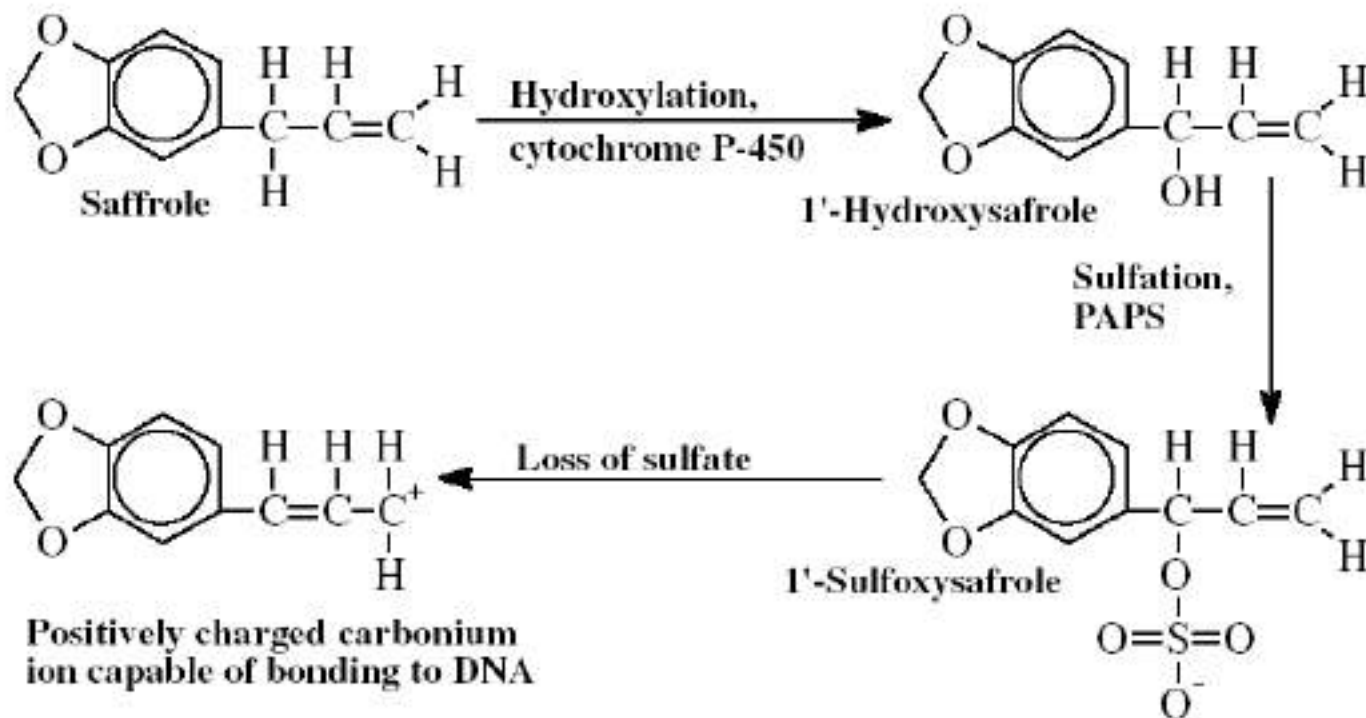

Phenol conjugation

Aromatic amine conjugation

Example of Toxic Sulfate Conjugate

Conjugation by Acetylate

Group transferred acetyl.

Cofactor Acetyl Coenzyme A.

Transfer is mediated by N-acetyltransferase enzymes (primary cytosol).

Types of substrate: amines (amine is converted into amide).

Sometimes acetyl conjugation occurs to detoxify substances (e.g. anilines) that could further produce other harmful metabolites!

Two types of acetylation reactions occur:

- one involves an activated conjugating intermediate, acetyl CoA, and the xenobiotic. The reaction is referred to as acetylation.
- the second type involves the activation of the xenobiotic to an acyl CoA derivative, which then reacts with all amino acid to form an amino acid conjugate.

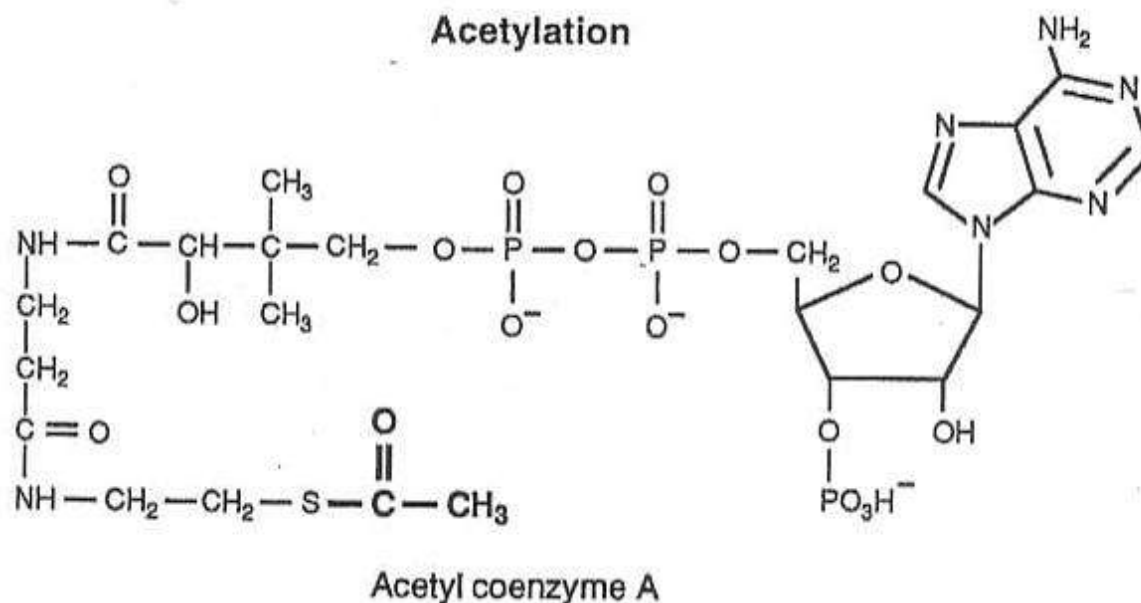

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Conjugation by Acetylate

Structure of Acetyl coenzyme A

Amino Acid Conjugation

Cofactor glycine or glutamine.

Amino acid conjugation occurs for a variety of carboxylic acids and the result is the formation of an amide bond to an amino acid, usually glycine or glutamine.

Transfer is mediated by Acyl CoA glycinetransferase (glutaminetransferase) enzymes (primary mitochondria).

Glycine is the most common conjugating amino acid in mammals.

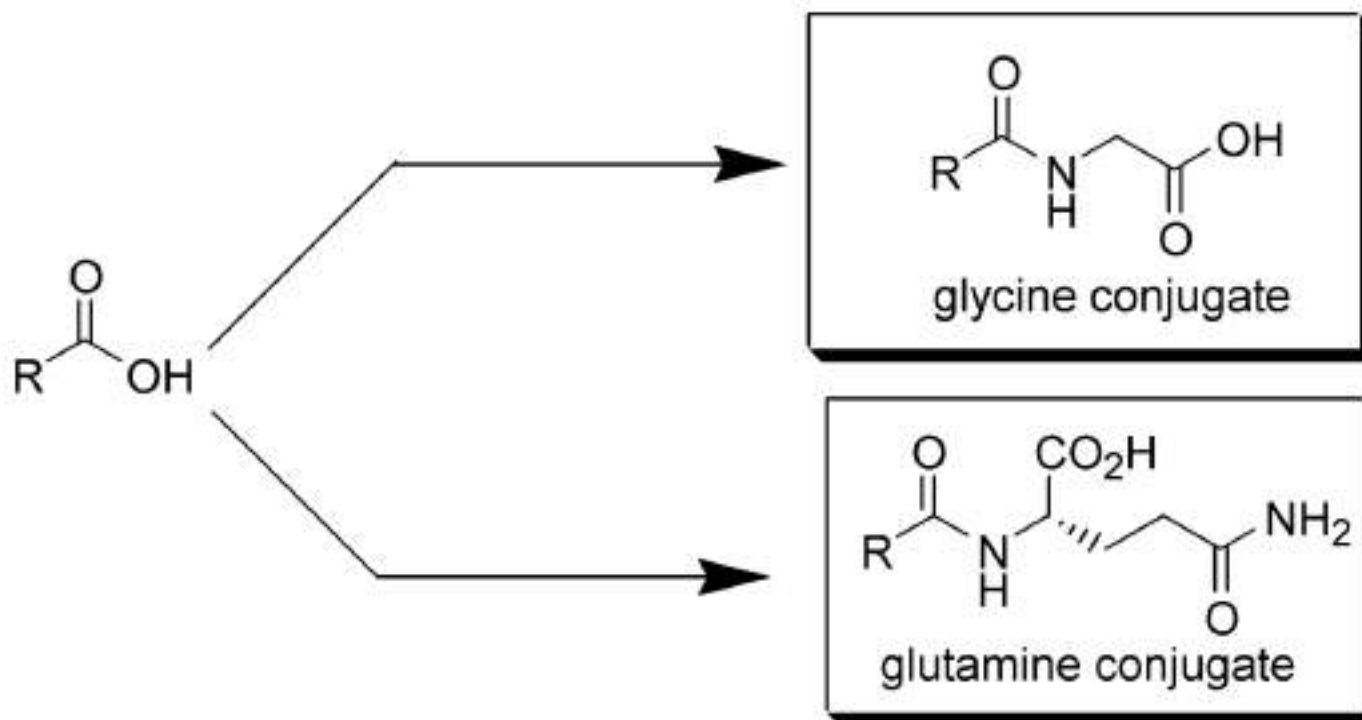

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Amino Acid Conjugation

Amino Acid Conjugation

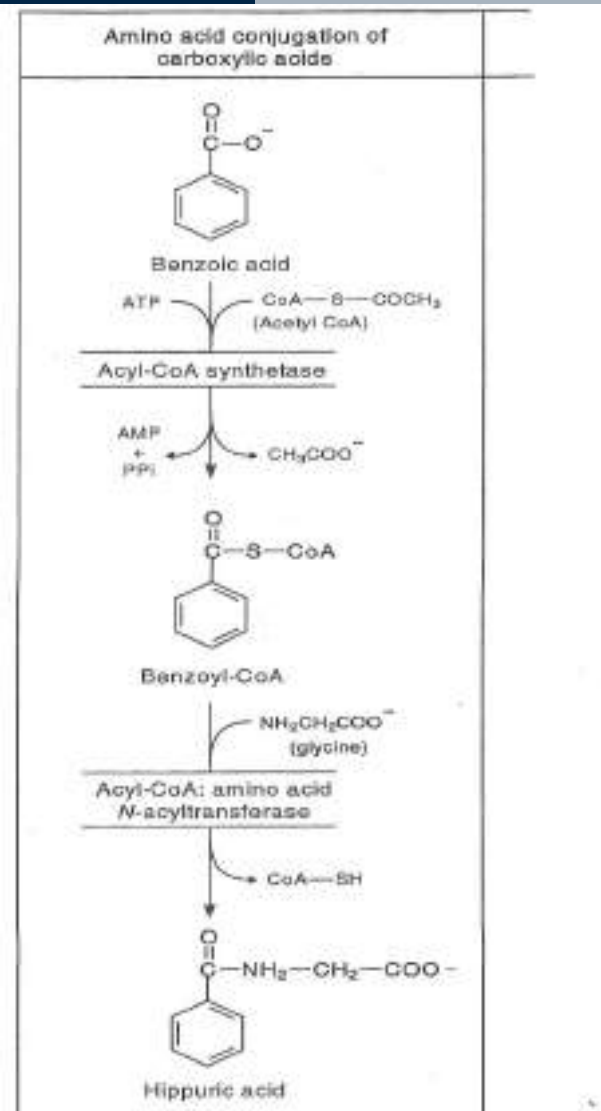

Figure 6-54. Conjugation of xenobiotics with amino acids.

Conjugation by methyl group

Group transferred methylate.

Cofactor S-adenosyl-methionine.

Transfer is mediated by transmethylase (primary cytosol).

Types of substrate: phenols, amines.

It is a common but generally minor pathway of xenobiotic metabolism.

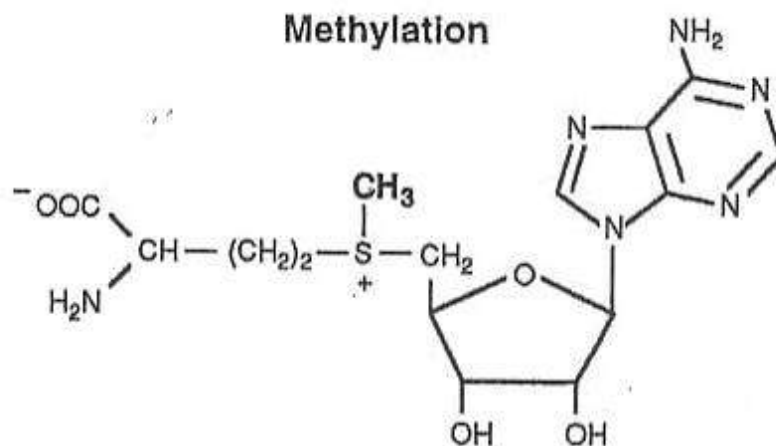

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

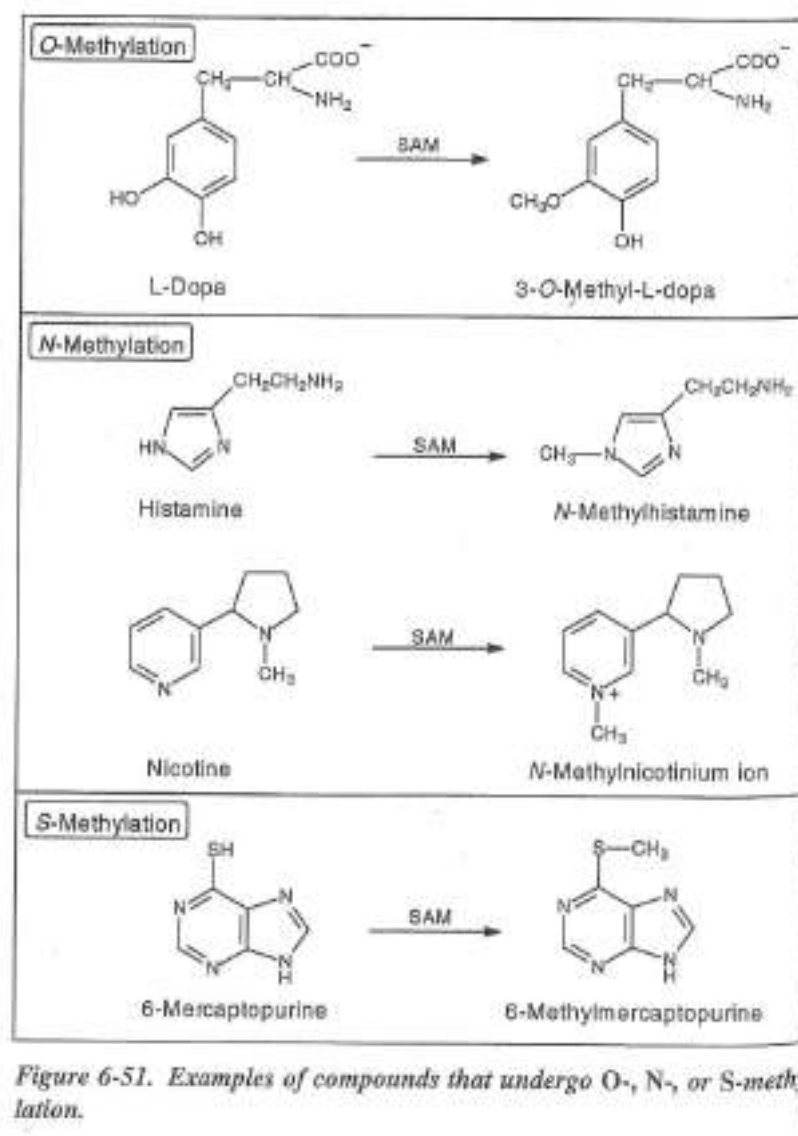

Conjugation by methyl group

Structure of SAM

Conjugation by methyl group

ENZYME INDUCTION

Results from repeated exposure to certain chemical substances.

The result of induction is an increase in the amount of an enzyme or isoenzyme.

Marked increase in rate of metabolism of chemical substance .

Depending on the role of metabolism in the toxicity of a chemical substance therefore, enzyme induction may increase or decrease in the toxicity of the chemical substance.

May also increase the metabolism of other chemical substance taken concurrently.

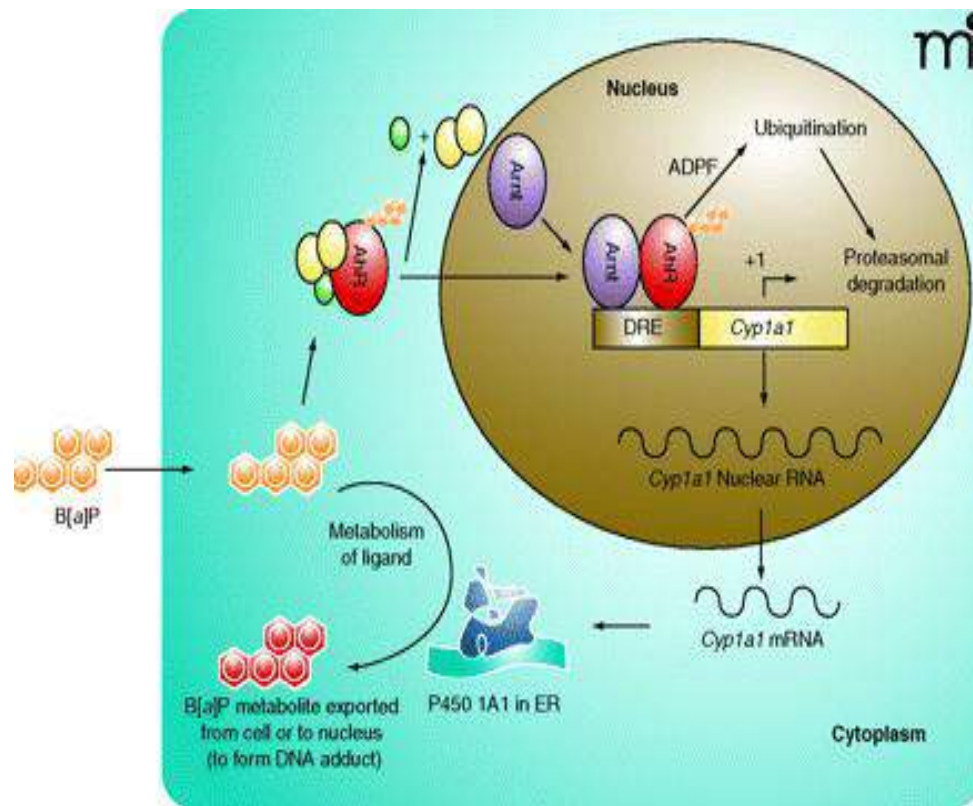

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

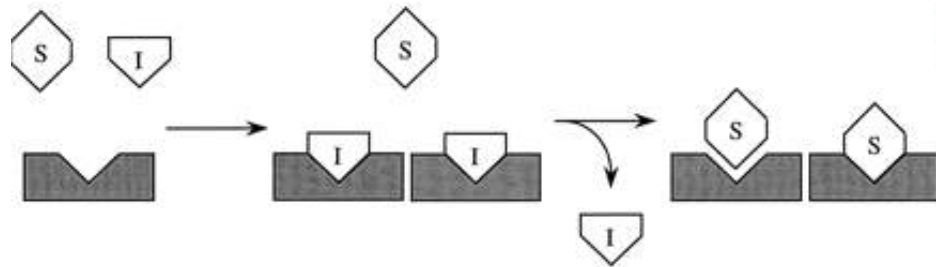

Induction by inducing the biosynthesis of the enzyme

Ah-locus mediated induction

Induction by stabilization

Stabilization of CYP2E1 by active site occupation.

Inducer and substrate are I and S, respectively, and CYP2E1 is represented by the shaded block.

Competitive inhibition of CYP2E1 occurs as the inducer binds to the active site, blocking substrate access.

As a consequence of binding, CYP2E1 accumulates due to stabilization.

As the inducer is removed, substrate regains access to the active site, and the metabolism of substrate is enhanced.

Induction of CYP1A1

TCDD binds to cytosolic AHR, releasing HSP90.

Complex moves to nucleus where it dimerizes with ARNT, exposing DNA binding motif.

Complex binds to DRE in 5'-flanking region of CYP1A1 gene, markedly (100-fold) increasing transcription.

mRNA transported to the ribosome and protein made.

Heme added and protein inserted into ER.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ENZYME INHIBITION

Some chemical substances can block P450 enzyme isoforms that metabolize other chemical substances (Grapefruit juice - CYP 3A4 inhibitor; fucocoumarins).

Depending on the role of metabolism in the toxicity of a chemical substance therefore, enzyme induction may increase or decrease in the toxicity of the chemical substance.

Unlike induction, enzyme inhibition usually begins with the first dose of the inhibitor.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Enzyme inhibition may be divided into several types involving:

- interaction of the chemical substance with the active site of the enzyme (OP)
- competitive inhibition by two different compounds at the same enzyme active site as with ethylene glycol and ethanol
- destruction of the enzyme as in the case with carbon tetrachloride
- reduced synthesis as with cobalt
- lack of cofactors such as glutathione

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Factors affecting metabolism

1. Chemical substances
2. Genetics variation
3. Nutritional state
4. Dose
5. Age
6. Gender
7. Disease state
8. Route of administration

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Excretion is the process by which a chemical substance or metabolite is eliminated from the body.

Only free unbound chemical substance or metabolite is available for excretion.

Chemical substances are eliminated from the body by various routes.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

EXCRETION URINE - KIDNEY

Renal (kidney) excretion is the primary removal mechanism for chemical substances.

Renal excretion is the result of three processes:

- passive glomerular filtration
- active tubular secretion in proximal tubules
- passive tubular re-absorption (diffusion)

Unchanged- metabolites

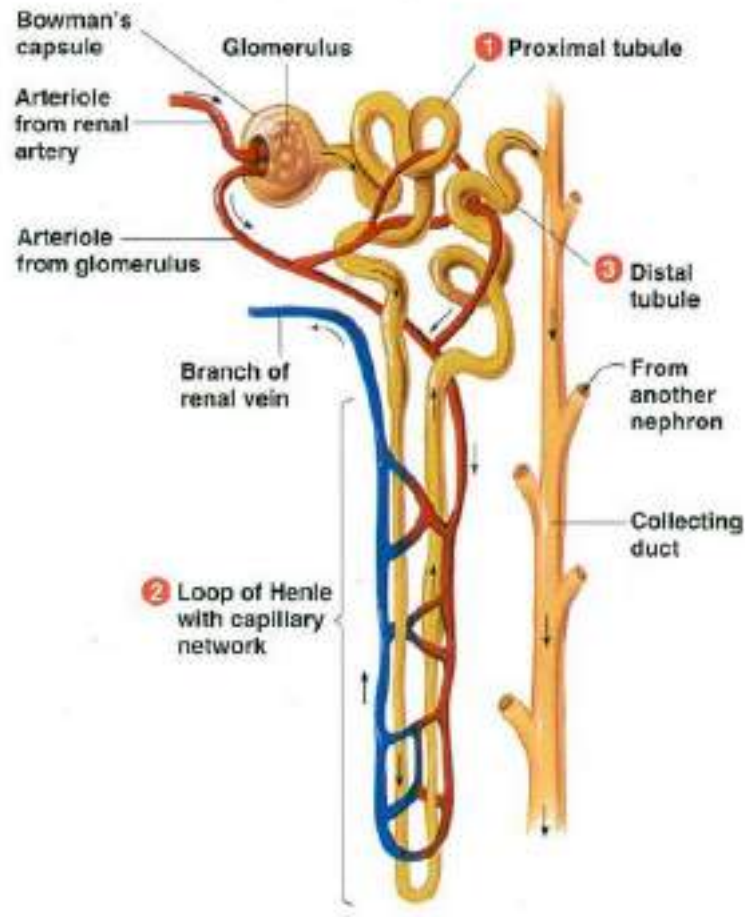

⇒ relatively small (< 100 molecular weight), water soluble

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Detailed structure of a nephron

EXCRETION URINE - KIDNEY

INFLUENCING FACTORS

- ⇒ urinary pH (change in urinary pH affect excretion)
- ⇒ rate of urinary flow
 - ↑ high fluid intake ⇒ ↑ facilitate excretion
- ⇒ kidney function
 - age, disease, simultaneous administration of other damaging compound
 - ⇒ functional – morphological changes
 - ↘ ↓ elimination

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

EXCRETION BILE - LIVER

The liver is the main site of biotransformation of chemical substances, the metabolites may be excreted directly into bile.

⇒ large, polar substances (> 300 molecular weight)

COMPOUND	Molecular weight	% of total excretion	
		urine	faeces
Biphenyl	154	80	20
Monochlorobiphenyl	188	50	50
Dichlorobiphenyl	223	34	66
Pentachlorobiphenyl	326	11	89
Hexachlorobiphenyl	361	1	99

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

EXCRETION BILE - LIVER

⇒ active gland process

⇒ may be saturated

Once a compound is excreted into bile and enters the intestine, it can be eliminated with feces.

colon (Hg, Fe, Bi)

saliva (Hg, Bi)

⇒ contact with gut bacteria

⇒ more lipid soluble compounds ⇒ reabsorption

⇒ enterohepatic circulation

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

EXCRETION LUNGS

Chemical substances that exist predominantly in the gas phase at body temperature are excreted by the lungs.

Volatile liquids in equilibrium with their gas phase may also be excreted via the lungs. Elimination of foreign gases is nearly inversely to the rate of gas uptake. Gases with low solubility in blood are rapidly excreted.

⇒ chemical substances are eliminated by diffusion from the blood into the alveolus

⇒ characteristic odor

cyanide	→ almond
phosphorous	→ garlic
hemlock	→ mouse-like

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

EXCRETION GIT

Appearance of chemical substances in feces can be due to a number of factors:

- the chemical substance was not completely absorbed after oral ingestion
- it was excreted into bile
- it was secreted in saliva, in gastric or intestinal secretory fluid, or in pancreatic secretion
- it was secreted by the respiratory tract and then swallowed

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

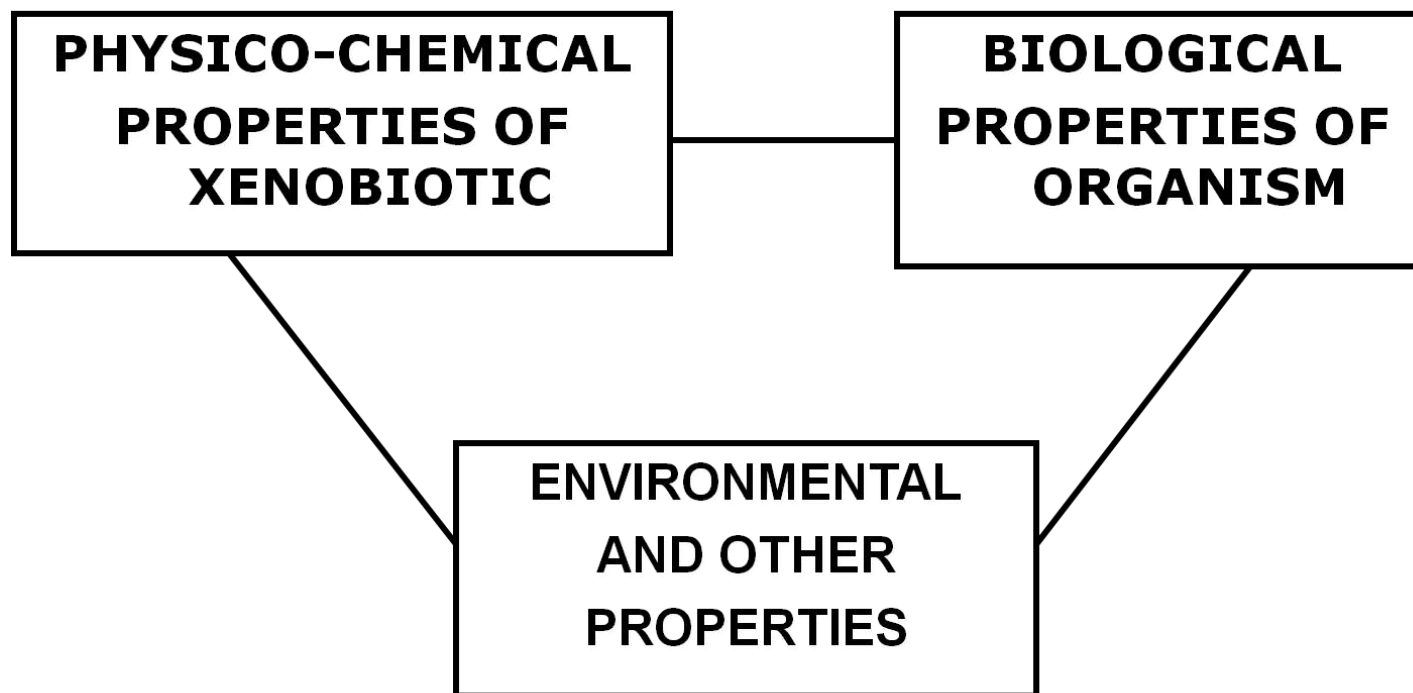

EXCRETION MILK

- ⇒ lipid soluble compounds (OC, dioxin, PCB, Se, As)
- ⇒ poisoning source
 - ⇒ nursing child
 - ⇒ food-toxicological importance ⇒ **PUBLIC HEALTH!**

EXCRETION EGG

- ⇒ lipophilic ⇒ egg yolk
- ⇒ hydrophilic ⇒ white of egg
- ⇒ **PUBLIC HEALTH PROBLEMS !**
- ⇒ **EXTINCTION OF WILD BIRDS !**

Factors influencing toxicity

I. PHYSICO-CHEMICAL PROPERTIES OF CHEMICAL SUBSTANCES

1. LIPOPHILICITY

Major importance for absorption + other phases of disposition

⇒ lipophilic ⇒ more readily absorb across membrane
⇒ more readily able to distribute

BUT ! excretion (kidney) ⇒ water solubility

major factor in toxicity ⇒ special membrane

2. MOLECULAR SIZE AND WEIGHT

Also of great importance in each phase of disposition

ABSORPTION

Small lipophilic molecule (generally, GI, skin)

Factors influencing toxicity

2. MOLECULAR SIZE AND WEIGHT

EXCRETION

Determine route of excretion

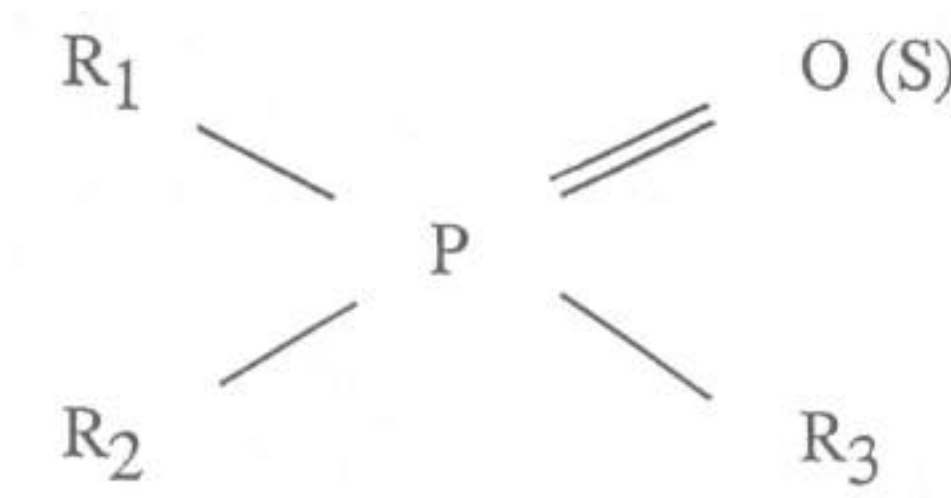

Chemical substance	Molecular weight	Rate of excretion (%)	
		urine	faeces
Biphenyl	154	80	20
Monochlorobiphenyl	188	50	50
Dichlorobiphenyl	223	34	66
Pentachlorobiphenyl	326	11	89
Hexachlorobiphenyl	361	1	99

3. CHEMICAL STRUCTURE

CHANGES OF STRUCTURE

minor changes \Rightarrow modify biologic action, toxicity

- ♦ Organophosphates O \uparrow - S \downarrow

3. CHEMICAL STRUCTURE

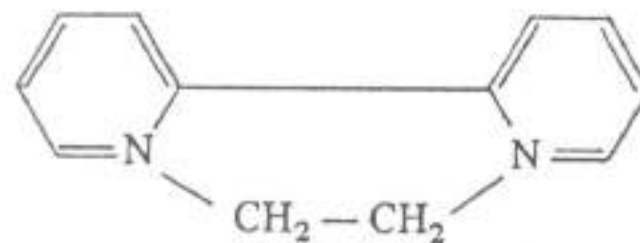

CHANGES OF STRUCTURE

♦ Bipiridyl

paraquat \rightleftharpoons diquat

Paraquat

Diquat

3. CHEMICAL STRUCTURE

CHANGES OF STRUCTURE

Allotropic

yellow phosphorous ✓ \Leftrightarrow red phosphorous Ø

Isomerization

ciss \Leftrightarrow trans (resmethrin)
LD₅₀ : 100 8000 mg/kg b.w.

4. IONIZATION

degree of ionization

⇒ basically affects toxicity

- ♦ non-ionized ⇒ lipophilic
- ♦ ionized ⇒ hydrophilic

MODIFY MEMBRANE TRANSPORT

QUICKEN the ELIMINATION

- ♦ salicylic acid-derivatives
dissociated in alkaline pH ⇒ Ø reabsorption
- ♦ strychnine (alkaloids), barbiturates
acidification ⇒ Ø reabsorption

II. BIOLOGICAL PROPERTIES OF ORGANISM

1. SPECIES

ANIMAL SPECIES	RELATIVE SENSITIVITY
Man	1.0
Horse, swine	0.5
Cattle, sheep, goat	0.3
Dog	0.2
Rat	0.1

Factors influencing toxicity

1. SPECIES

SENSITIVITY

thalidomide animal ⇔ human

DIOXIN

ANIMAL SPECIES	LD ₅₀ (mg/kg)
Guinea-pig	0.5-2
Rat	22-100
Mouse	114-284
Rabbit	10-115
Chicken	25-50
Rhesus monkey	< 70
Dog	> 30-300
Hamster	5051

Factors influencing toxicity

1. SPECIES

ANATOMICAL differences

GI length and parts of GI

dog short, efficient digestive tract
absorption more rapid, completed
> herbivora

SKIN cat > dog
more permeable to OP

VOMITING !!!

horse, rat, rabbit ⇒ unable to vomit
anatomical – physiologic ↗
⇒ toxic effect ↑

1. SPECIES

PHYSIOLOGIC differences

plant \Rightarrow ruminants \emptyset

metals \Rightarrow ruminants \uparrow

gase \Rightarrow birds \uparrow

kidney capacity: \downarrow bird $<$ mammals

CAT \Rightarrow METABOLISM differences

Factors influencing toxicity

1. SPECIES

METABOLISM

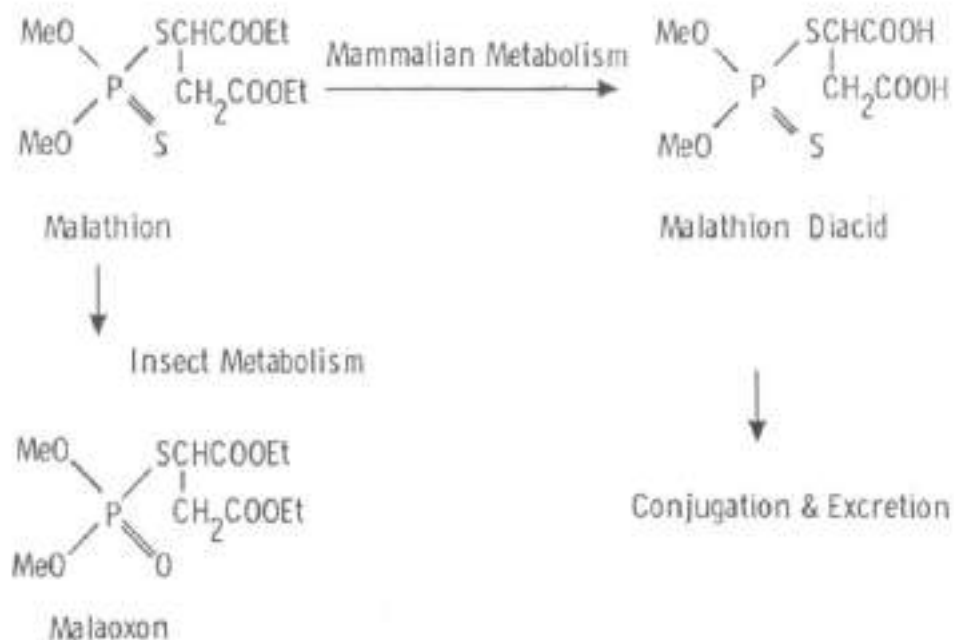

„relative” deficiency – enzyme deficiency

SPECIES	PHENOL CONJUGATION (% total)	
	GLUCURONIDE	SULFATE
CAT	0	87
Man	23	71
Rat	25	68
Rabbit	46	45
Guinea-pig	78	17
SWINE	100	0

Factors influencing toxicity

1. SPECIES

METABOLISM

Factors influencing toxicity

1. SPECIES - STRAIN

OP Brahman cattle > Hereford cattle

Thiourea i.p. LD₅₀ (mg/kg)
rat strains

Hopkins: 4 < Harward: 44 < Norway rat: 1340-1840

2. SEX

MALES

metabolize more rapidly

⇒ results in lower toxicity

⇒ metabolize ⇒ more toxic metabolite

⇒ higher toxicity

Factors influencing toxicity

3. AGE

YOUNG – GERIATRIC individuals

- ⇒ more sensitive
- ⇒ metabolizing activity
- ⇒ plasma-protein binding capacity
less efficient

parent chemical ⇒ more toxic

! Converse is also true

require metabolic activation for toxicity
⇐ less toxic

4. HEALTH STATUS

LIVER, KIDNEY function

hepatic/renal disease ↑ susceptibility

CONDITION

fat tissue ⇒ storage ⇔ toxicity ↓
 ⇐ starvation ⇔ lipolysis ↑
 ⇐ re-distribution (OC)
 + toxicity ↑

III. ENVIRONMENTAL AND OTHER PROPERTIES

1. FOOD - WATER

Composition – nutritional status

⇒ influence disposition, toxicity

DISADVANTAGE

HIGH FAT (LIPID)-content

⇒ dissolving, absorption ↑

1. FOOD - WATER

DISADVANTAGE

- ♦ **PROTEIN INSUFFICIENCY diet**
 - ⇒ ↓ microsomal enzyme activity
 - ⇒ ↓ level of plasma proteins (binding)
- ♦ **MINERAL/VITAMIN DEFICIENCY**
 - ⇒ ↓ metabolism
- ♦ **STARVATION**
 - ⇒ ↓ supply of essential cofactors (sulphate, glutathione)

1. FOOD - WATER

DISADVANTAGE

- ♦ WATER

- ⇒ insufficient – deprivation

- ↑ possibility of poisoning (NaCl)

- ⇒ source of poisonings

- fertilizers, industrial emission etc.

Factors influencing toxicity

2. ENVIRONMENT

TEMPERATURE ↓

SUNSHINE – DIRECT SUNLIGHT ↓
facilitate the degradation (OP)

HUMIDITY ↓
destroy during storage

pH ↑ ↓

MICROBIAL ACTIVITY ↑ ↓

Definition of Teratology

The study of abnormal development in embryos and the causes of congenital malformations or birth defects.

- Structural malformation
- Growth retardation
- Functional disorder
- Death of the organism

TÁMOP-4.1.2.A/2-10/1-2010-0012

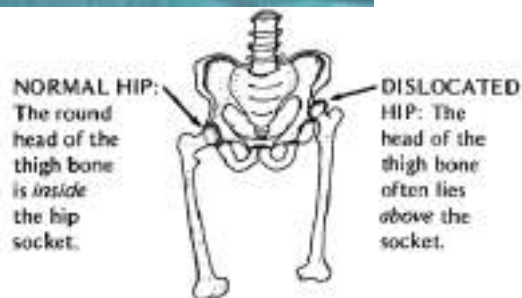

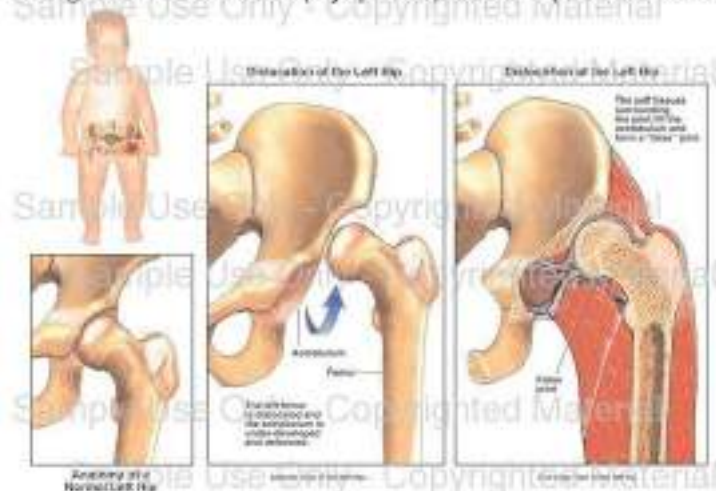

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Congenital Dislocation (Dysplasia) of the Hip in an Infant

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Malformation

Congenital malformation are structural defects present at birth. They may be gross or microscopic, on the surface of the body or within it, familiar or sporadic, hereditary or nonhereditary, single or multiple. (Warkany, 1947).

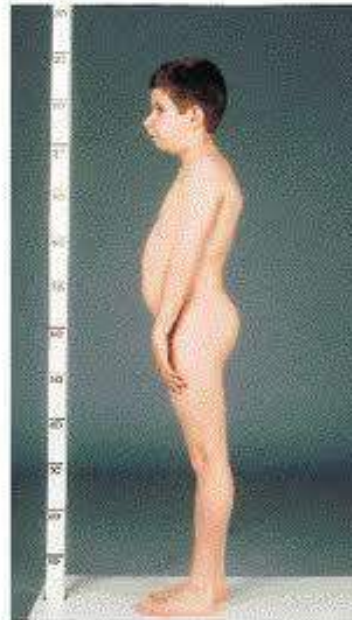

A major congenital anomaly is one that is incompatible with survival, is life-threatening, or seriously compromises an individual's capacity to function normally in society (Otake et al., 1990).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Growth retardation

Functional disorders

- Inborn errors of metabolism
- Physiological disturbances
- Mental retardation
- Cellular and molecular abnormalities

Teratogenicity

Congenital defects are the #1 cause of death in infants.

Observed in 3% of newborns.

Observed in another 3% of children later.

May or may not be outwardly visible.

Etiology: genetic and environmental.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Factors influencing teratogenicity

- Genetic susceptibility
- Gestational timing
- Frequency and duration of exposure
- Nature of the agent (specificity)
- Dose

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Genetic susceptibility

Different in genotype \Rightarrow different in sensitivity

– species, breed, phylum...

- Differences in metabolic pathways and products.
- Anatomical differences (humans 1, rodents and rabbits 2).

Acetylsalicylic acid (humans \emptyset , rodents \checkmark).

Thalidomid (humans \checkmark , rodents \emptyset).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Gestational timing

The total period of intrauterine development can be divided into three parts.

1. Preimplantation

- Begins when egg is fertilized in the fallopian tube.
- Period of rapid cell division.
- Ends 2 weeks later when the zygote is implanted in the wall of the uterus.
- „All or none” phenomenon. („All” → early abortions, „None” → reorganisation (cell division) → healthy newborn.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Gestational timing

2. Organogenesis

- From 3 to 8 weeks after conception.
- Body parts are formed during this period.
- In general it can still be said that this period is one of great vulnerability. The teratogens can damage the embryo, leading to defective development or even death. Each organ system also has its own critical period when it is most vulnerable.
- The period of maximum sensitivity to a teratogen corresponds to the 'critical period of organogenesis: during early organogenesis, malformations of the CNS, eyes and limbs occur; later in organogenesis, the ears, external genitalia, teeth and palate are affected.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Gestational timing

3. Foetogenesis (foetal development)

- From 9 weeks after conception to birth.
- Increase in size and systems begin to function.
- This is the longest part of prenatal development. The foetus becomes less susceptible to teratogenic effects.
- During subsequent histogenesis and functional maturation, structural tissue defects and/or functional loss (growth/CNS abnormalities and behavioural effects), plus growth retardation as a consequence of general cell necrosis are common.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Gestational timing

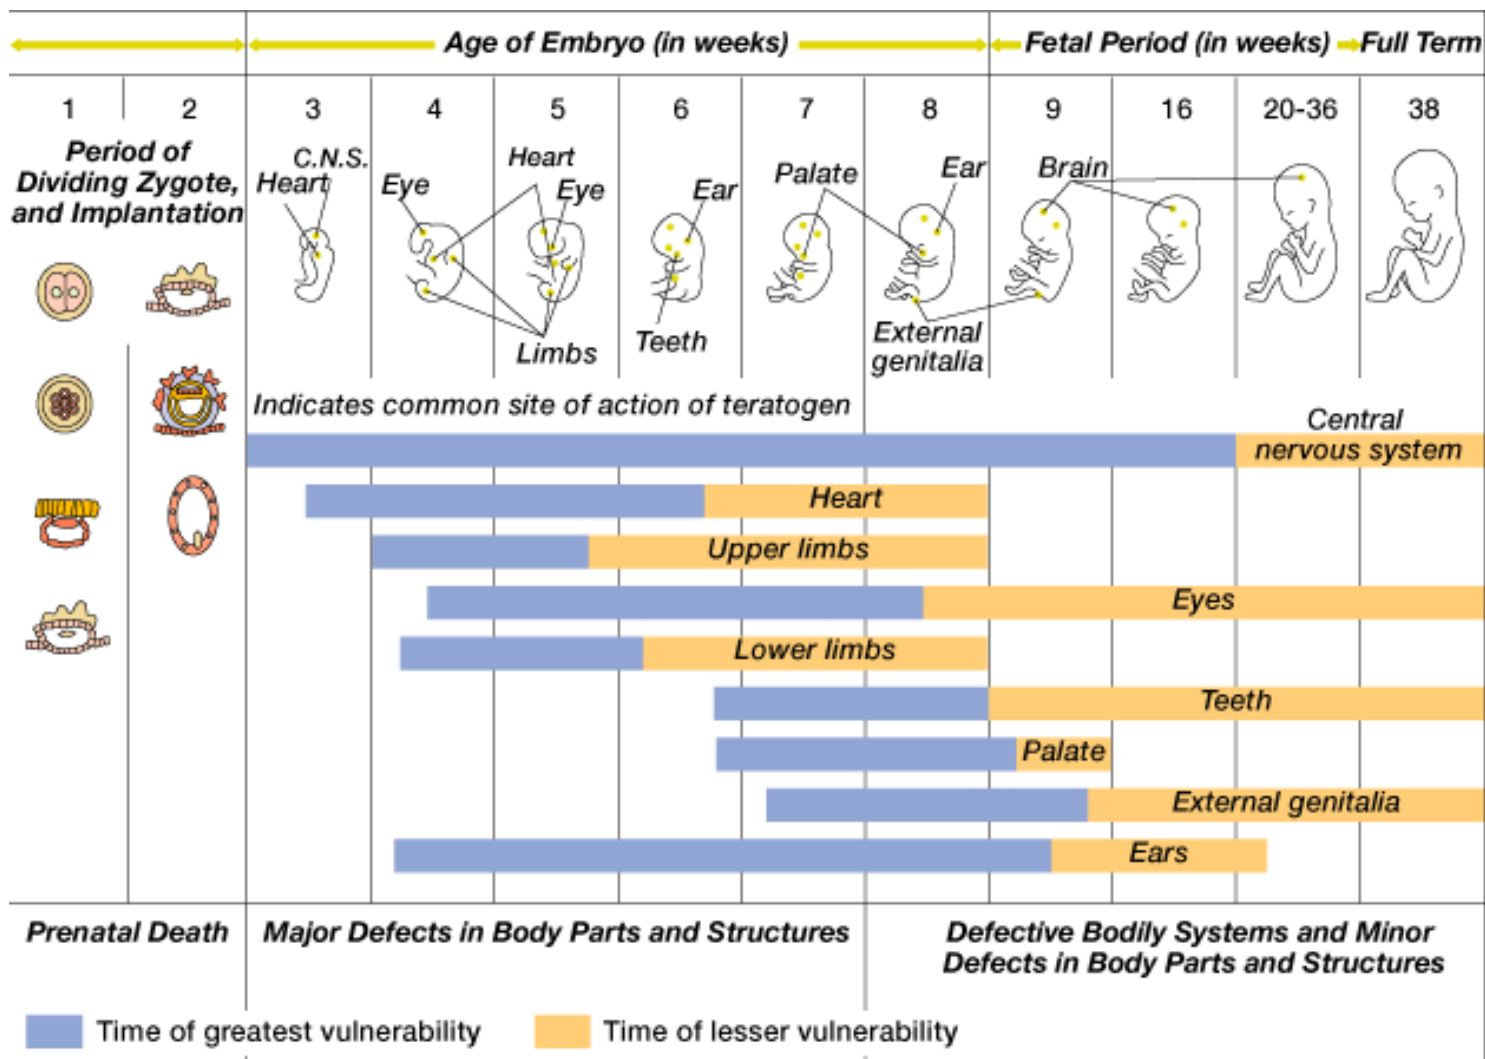

Main parts of intrauterine development	Rat	Rabbit	Humans
Preimplantation	5-6 days	5-6 days	6-8 days
Organogenesis	8-9 days	12-14 days	50-60 days
Foetogenesis	6-8 days	13-15 days	200- 220 days

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Frequency and duration of exposure

In case of a continuous exposure of a teratogenic agent the abnormalities, connecting with the main parts of intrauterine development appear cumulatively.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Nature of the agent (specificity)

The site of action of the teratogens are different in the organism.

⇒ different types of teratogens

⇒ similar abnormalities → given during the same critical period

⇒ same teratogens

⇒ at different times → different effects

Thalidomid – phocomelia

Hypervitaminosis A – spina bifida, eye deformities, cleft palate

Warfarin – skeletal and CNS abnormalities

Alkohol – FAS

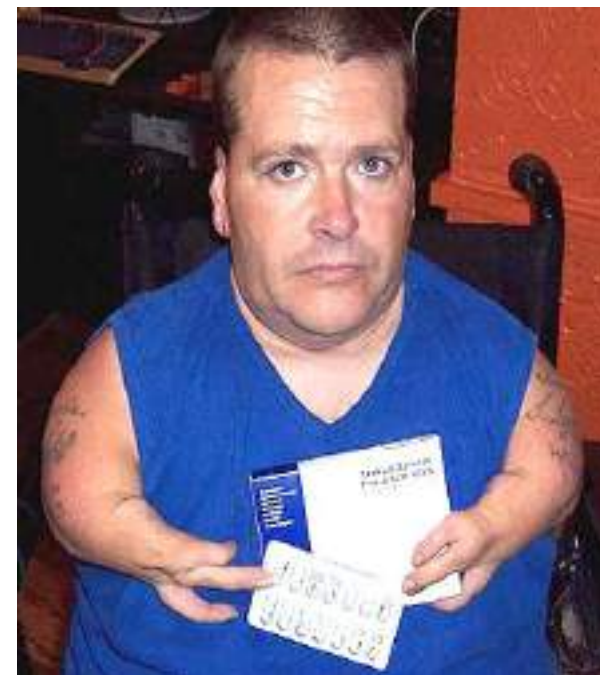

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Befektetés a jövőbe
Új Magyarország
FEJLESZTÉSI TERV

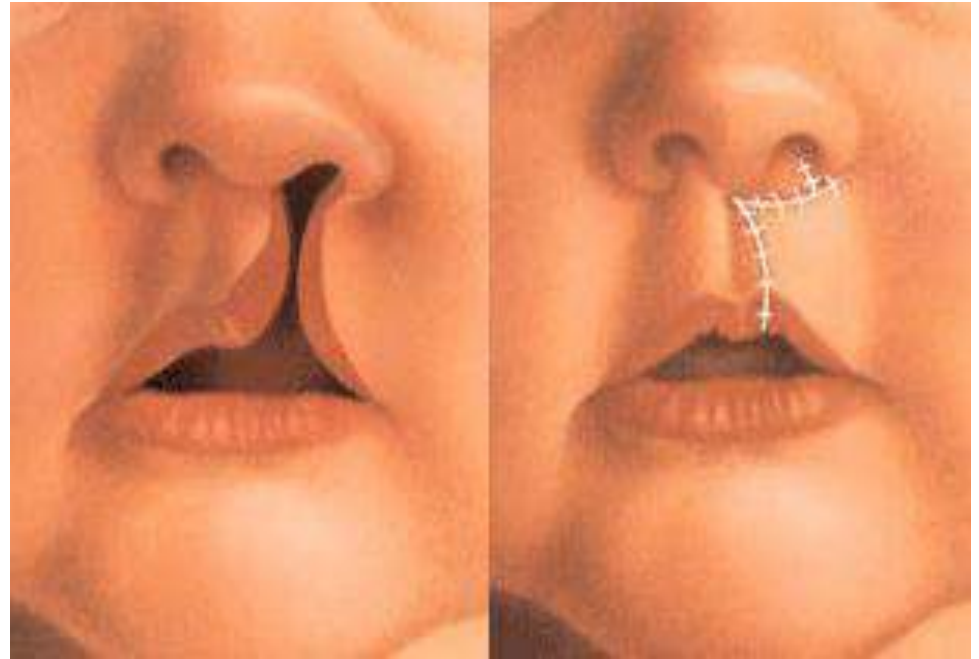

Teratogenicity

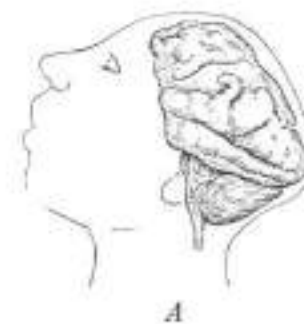

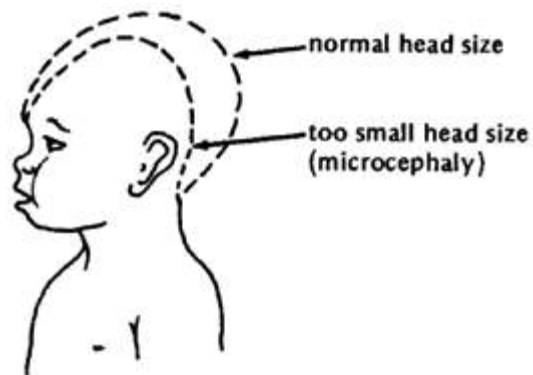

Unilateral cleft lip & palate

Bilateral cleft lip & palate

Teratogenicity

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

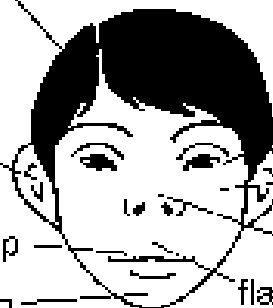

Normal

small head circumference

simply formed
low-set ears

thin upper lip

small chin

FAS

smaller eye openings
under eye folds

flat midface

short, upturned nose

flat, elongated philtrum
(grooves above lip)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Befektetés a jövőbe
Új Magyarország
FEJLESZTÉSI TERV

Dose

Exposures to teratogenic agents only result in teratogenic effects when a certain threshold dose has been exceeded.

For every teratogen there is a level of exposure below which no adverse effect to the embryo occurs, known as the 'no observable effect level' (NOEL); above this threshold, teratogenic effects steadily increase in a dose-response relationship.

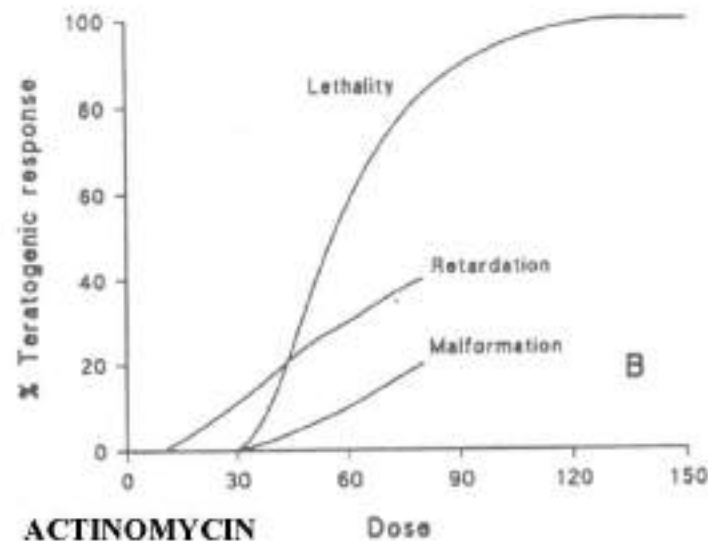

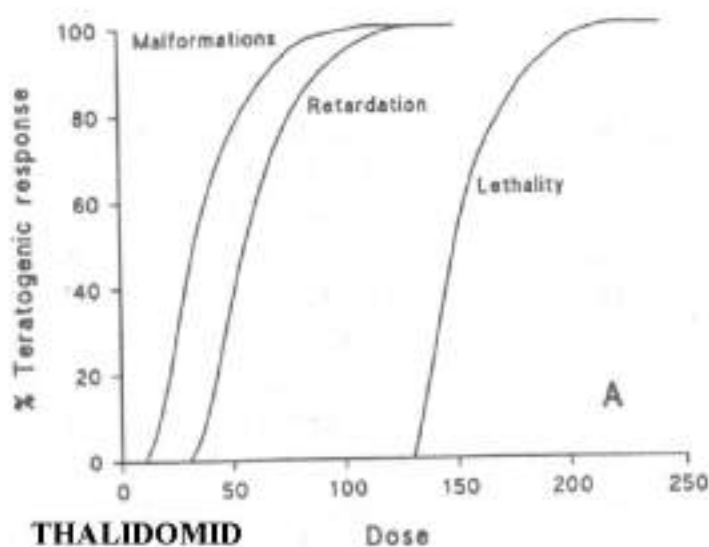

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Increasing doses

– ineffective → teratogenic effect (malformation, growth retardation) → fatal to embryo → maternal toxicity → fatal to mother.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Karnofsky's Law:

„ Anything can be teratogenic if given in the right dose, to the right species, at the right time.”

This may well explain the inclusion of various everyday substances, which are essential for life itself, in the list of teratogens in 'Dangerous Properties of Industrial Materials@ (Lewis, 1989). These include drinking water (Turbow *et al.*, 1971) and table salt (Nishimura and Miyamoto, 1969); oxygen; sugars in the form of sucrose and lactose; palm oil, corn oil and nutmeg oil; other naturally occurring food constituents such as cholesterol and papain (prevalent in pineapples); vitamins such as A, D2, K, B7 and B12 (the B vitamins are frequently found in pregnancy supplements); naturally occurring and essential hormones such as estradiol, progesterone and various prostaglandins; the amino acid methionine, and the DNA constituent adenine.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

CAUSES OF CONGENITAL MALFORMATIONS

I. Anomalies caused by genetic factors (~20%)

- Chromosomal abnormalities
- Single gene defects

1. Chromosomal abnormalities

- Numerical chromosomal abnormalities

Down syndrome (21), Edwards (18), Patau (13), Turner (X0), Klinefelter (XXY).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Down syndrome is caused by non-disjunction of the 21st chromosome during meiosis. As a result, the child has three 21st chromosomes instead of the normal two. Symptoms: characteristic facial features, congenital heart disease, growth retardation, and mental retardation.

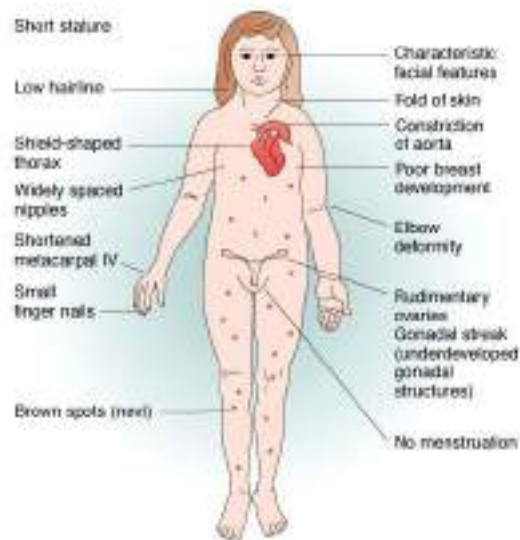

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Monosomy of the X-chromosome is referred to as **Turner syndrome**. Turner syndrome is a rare, exclusively female disease. Because Turner syndrome affects one of the X chromosomes in women, girls affected with this condition often also experience delayed and underdeveloped sexual characteristics, as well as infertility.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

1. Chromosomal abnormalities

- Structural chromosomal abnormalities

translocations (exchange of material between chromosomes), inversions, deletions or duplications - Cri du chat syndrome.

2. Single gene defects

Achondroplasia, Fragile-X syndrome.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Cri du chat syndrome is one of the more common deletion syndromes, involving the short arm of chromosome 5.

The syndrome gets its name from the characteristic cry of affected infants, which is similar to that of a meowing kitten, due to problems with the larynx and nervous system.

Other symptoms: low birth weight and poor growth, behavioral problems such as hyperactivity, aggression, unusual facial features which may change over time.

Facial features of a child with Cri du Chat syndrome at age of 8 months (A), 2 years (B), 4 years (C) and 9 years (D).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Achondroplasia is a disorder of bone growth.

All persons with achondroplasia are little people. The average height of an adult with achondroplasia is 131 cm in males and 124 cm in females.

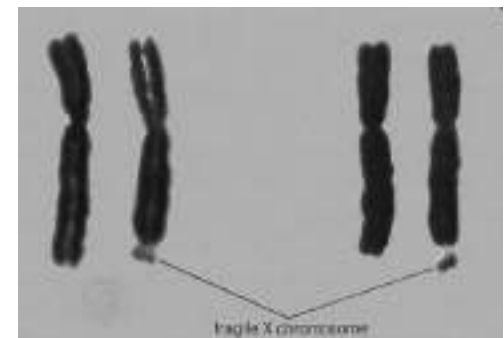

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Fragile X syndrome is associated with the FMR1 gene, which is on the X chromosome. Mutations in the FMR1 gene cause fragile X syndrome. The FMR1 gene provides instructions for making a protein called fragile X mental retardation 1 protein. This protein likely plays a role in the development of synapses, which are specialized connections between nerve cells.

- The severity of the condition varies and a child may have slight learning disabilities, autism or severe mental retardation.

II. Anomalies caused by environmental factors (3-9%)

1. Intrauterine infections (2-3%)

- *Rubella virus*
- *Cytomegalovirus*
- *Herpes simplex virus*
- *Varicella-Zoster virus*
- *Epstein-Barr virus*
- *Parvovirus B19*,
- *Toxoplasma gondii*
- *Treponema pallidum*

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

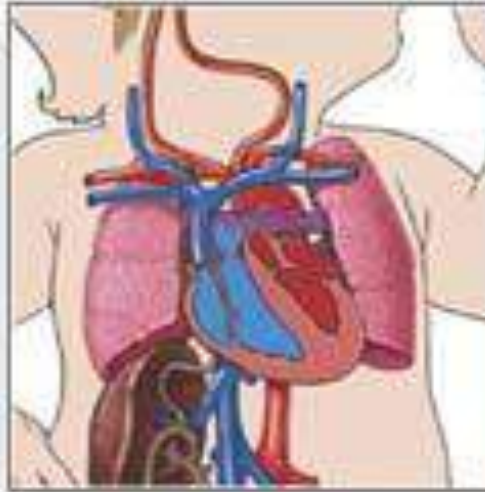

Disease	Birth Defects
Rubella	Cataracts, glaucoma, heart defects, deafness, mental retardation, bone alterations, liver and spleen damage
Cytomegalovirus	Microcephaly, blindness, mental retardation
Herpes simplex	Microphthalmia, microcephaly, retinal dysplasia
Toxoplasmosis	Hydrocephalus, cerebral calcifications, microphthalmia
Syphilis	Mental retardation, deafness, miscarriage, neonatal death, IUGR, stillbirth, premature delivery
Varicella	Cortical atrophy, seizures, chorioretinitis, cataracts, microphthalmia, hypotrophic limbs, hemiatrophy, skin lesions
Parvovirus B -19	Fetal aplastic crisis, intrauterine fetal death

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Rubella Syndrome

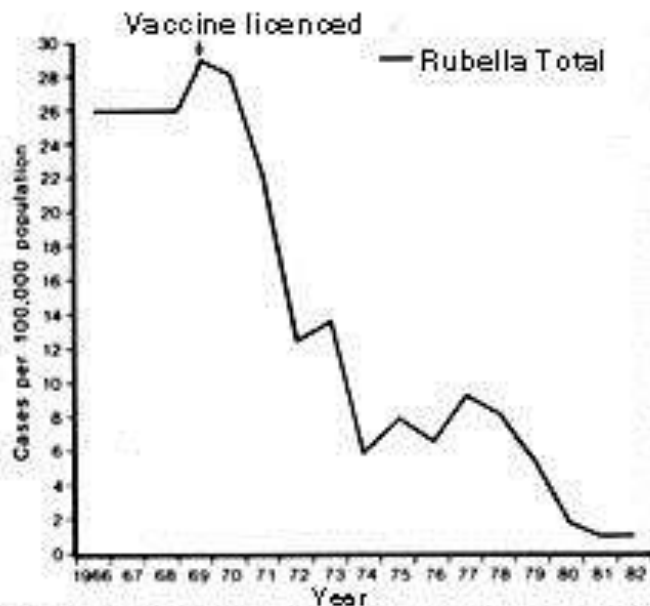

Teratogenicity

In the past, the most common intrauterine infection with a teratogenic agent was rubella. Rubella cases drop after vaccination starts.

Child with congenital rubella syndrome (South 1986).

Decrease in rate of rubella cases in the U.S. between 1966 and 1982. A complementary reduction in congenital rubella syndrome was also observed (South 1986).

Teratogenicity

Cytomegalovirus is the leading viral cause of congenital abnormalities. 0.2-2% of all infants are infected in utero. 10% of these will develop brain damage.

a) Newborn with CMV infection: note microcephaly. b) Same patient 8 years later with microcephaly, mental retardation and spastic quadriplegia. She is feed through a gastrostomy tube (Reynolds 1986).

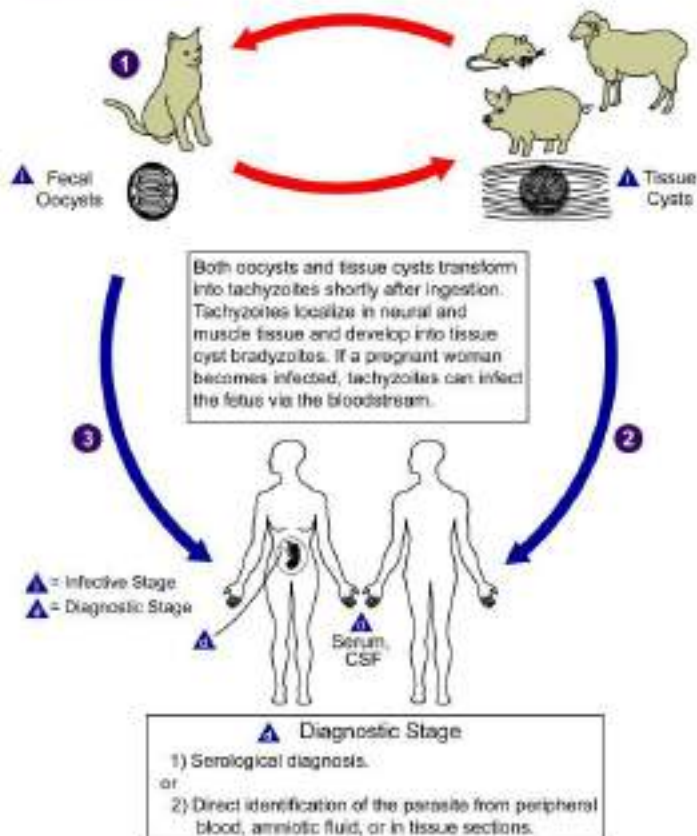

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Toxoplasmosis

(*Toxoplasma gondii*)

A fetus may contract toxoplasmosis through the placental connection with its infected mother

The mother may be infected by:

Improper handling of cat litter

Handling or ingesting contaminated meat

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

II. Anomalies caused by environmental factors (3-9%)

2. Maternal metabolic disorders (1-2%)

- Diabetes mellitus (congenital heart disease, renal, gastrointestinal, and central nervous system malformations)
- Hyperthermia (spina bifida and anencephaly)
- Phenylketonuria (mental retardation, low birth weight, and congenital heart disease)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

II. Anomalies caused by environmental factors (3-9%)

3. Ionizing radiation (1-2%)

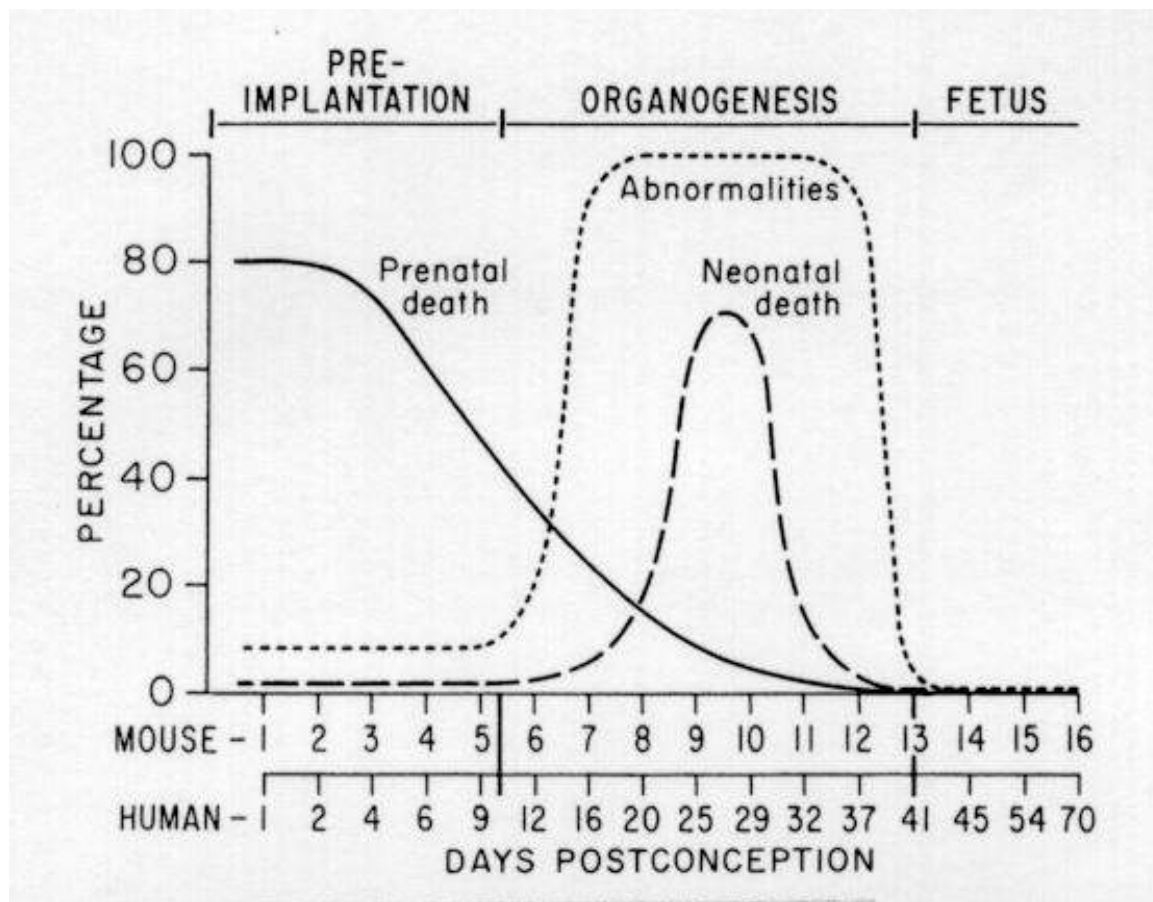

- Growth retardation
- Congenital malformation (microcephaly, microphthalmia, spina bifida, mental retardation, cleft palate..)
- Embryonic, fetal or neonatal death
- Delayed toxic effect (increased incidence of cancer – leukemia)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Embryo is radiosensitive. Embryonic cells have high rates of cell division and cell differentiation.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Effects of Irradiation on the Human Embryo^a

Days after Fertilization	Period of Development	Effects
1-9	Preimplantation	Most probable effect: death, with little chance of malformation
10-12	Implantation	Reduced lethal effects; malformation still unlikely; intrauterine growth retardation (IUGR) predominant effect
13-50	Organogenesis	Production of congenital malformation; retarded growth
51-280	Fetal	Effects on central nervous system; growth retardation with higher doses
All		Increased incidence of cancer and leukemia?

Source: Kirchner (1980), p. 86.

^aBased on mouse and rat studies.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

II. Anomalies caused by environmental factors (3-9%)

4. Drugs (1%)

- Anticonvulsants (Trimethadione, Valproic acid)
- Antimicrobial agents (Tetracycline)
- Anti-cancer chemotherapeutic agents (Cyclophosphamide, Aminopterin, Methotrexate)
- Oestrogens (Diethylstilbestrol)
- Antimalarial agents (Quinine)
- Sedatives (Thalidomide)
- Anticoagulant (Warfarin)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Valproic acid was released in 1967 in Europe and in 1978 in the United States to treat epilepsy.

Approximately 11,500 epileptic women become pregnant each year, many of which use valproic acid.

By 1980, publications began linking malformed children to in utero exposure to valproic acid (greater than 500 mg/day).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

These children were born with lumbosacral spina bifida with menigomyelocele or meningocele, often accompanied by midfacial hypoplasia, deficient orbital ridge, prominent forehead, congenital heart disease and decreased postnatal growth. The proposed mechanism of action is that valproic acid influences folate metabolism, thereby altering the closure of the spinal column resulting in spina bifida.

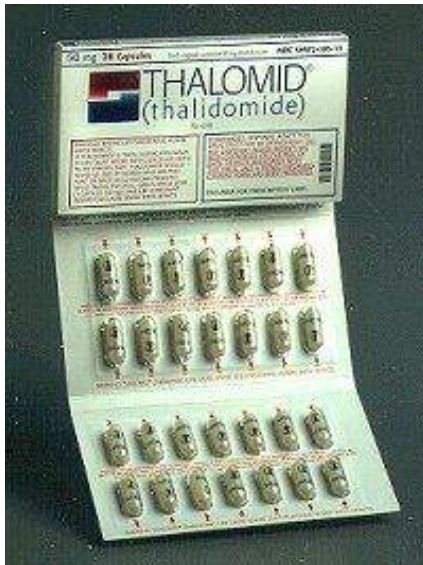

Teratogenicity

On October 1, 1957, Chemie Grünenthal introduced Thalidomide as sedative (sleeping pill).

It became popular as both a sedative and a morning sickness treatment during pregnancy.

3rd best selling drug in Europe.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Unfortunately molecules of the thalidomide chemical crossed the placenta and disrupt the growth patterns of the growing embryo.

10000 to 12000 infants were affected.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Phocomelia

Amelia = absence of limbs

Phokos = seal

Phocomelia = seal limbs

Sketches by Aldrovandus (1642) of a fetus with a phocomelic arm and an epigastric parasite (Wilson 1977).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Warfarin is a synthetic derivative of coumarin, a chemical found naturally in many plants (sweet clover..).
It decreases blood coagulation by interfering with vitamin K metabolism.
Inhibits biosynthesis of vitamin K-dependent zymogens

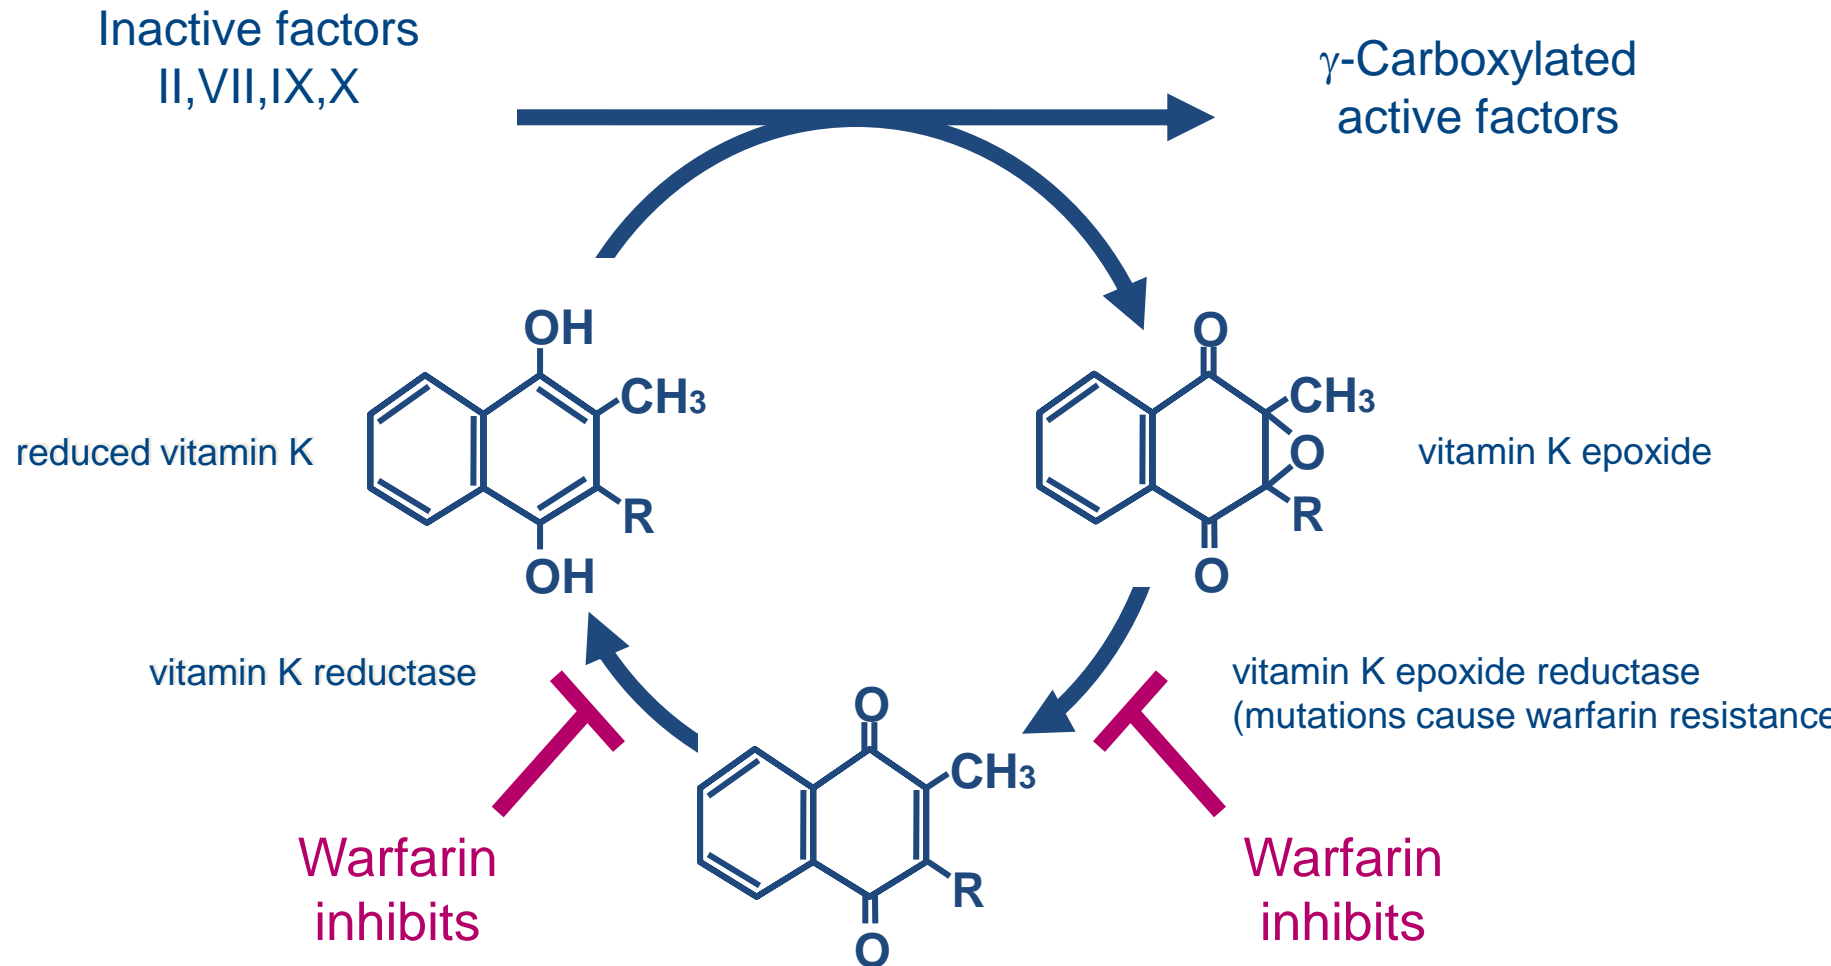

Yellow Sweet Clover
(*Melilotus officinalis*)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Vitamin K cycle

Teratogenicity

Warfarin is used to prevent thrombosis (clots) and embolism in many disorders.

It was initially marketed as a pesticide against rats and mice and is still popular for this purpose. A few years after its introduction, warfarin was found to be effective and relatively safe for preventing thrombosis and embolism in many disorders.

It was approved for use as a medication in the early 1950s and has remained popular ever since.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Fetal Warfarin Syndrome: infant with hypoplastic nose, flat face and low nasal bridge as well as altered calcification (Smith 1982).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

II. Anomalies caused by environmental factors (3-9%)

5. Environmental chemicals (4%)

- Dioxin
- Heavy metals: Pb, Cd, Hg
- Abusus drugs: cocaine, heroine

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Fetal Minamata Disease

In 1955 in the Minamata Bay area of Kyushu, Japan, there was a large influx of cases of severe neurological disorders in newborn children. Some villages had 6-12% of their newborns affected.

In 1959, it was found that mercury was being dumped into the bay by a plant of the Chisso Corporation.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Befektetés a jövőbe
Új Magyarország
FEJLESZTÉSI TERV

Teratogenicity

Inorganic mercury from Chisso plant discharge into downstream bay, converted by bacteria into methyl mercury.

It is concentrated in the flesh of fish.

Teratogenicity

Children with Congenital Minamata Syndrome seem to be normal at birth and begin to present symptoms at approximately six months of age. They have instability of the neck, convulsions, reduced IQ, microcephaly, malformed limbs, restricted growth and an altered cerebellum. In utero exposure to methyl mercury induces general brain atrophy and hypoplasia.

Children with Congenital Minamata Disease due to intrauterine methylmercury poisoning (Harada 1986).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

III. Anomalies caused by multifactorial or unknown factors (65-75%)

Many birth defects are caused by a combination of genetic and environmental factors. These conditions are said to have multifactorial ("many factors") inheritance.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Fetal Alcohol Syndrome is among the most commonly known causes of mental retardation and is a major public health problem.

Teratogenicity

Historical view of alcohol as a teratogen

„Foolish, drunken, or harebrain women most often bring forth children like unto themselves „

Aristotle in *Problemata*

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

FAS

- Specific pattern of facial features
- Pre- and/or postnatal growth deficiency
- Evidence of central nervous system dysfunction (degeneration)

Brain damage resulting from prenatal alcohol

Mutation

Damage/chemical modification of genetic components (DNA or chromosome) of the cell.

Mutagen

Physical or chemical agent that interacts with DNA to cause a mutation, so the resulting mutation is induced, not naturally occurring and usually at much higher frequency.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Genotoxic agents

1. DNA reactive chemical substances

- base analogues (e.g. 5 bromouracil)
- covalent bonders (alkylating agents, bulky adducts)
- oxidative chemical agents (free radicals can damage DNA)
- intercalators (e. g. acridine, ethidium bromide, proflavin)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

2. Physical mutagens

High-energy ionizing radiation: x-rays and g-rays → strand breaks and base/sugar destruction (cause extensive chemical alterations).

Nonionizing radiation: UV light → thymine dimers from adjacent.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Types of mutagens

- ♦ **Primer**

- ⇒ act directly (parent molecule)
(alkylating agents)

- ♦ **Secundaer**

- ⇒ become mutagens after metabolism
(benzpirene, nitrosamines)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Mutagenicity

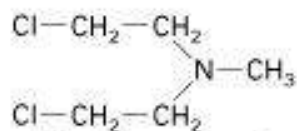

DIRECT-ACTING CARCINOGENS

Ethylmethane sulfonate (EMS)

Dimethyl sulfate (DMS)

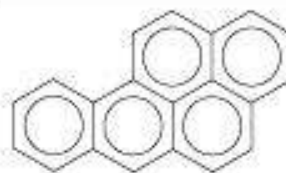

Nitrogen mustard

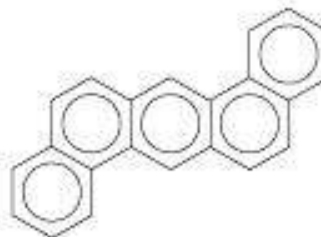

Methyl nitrosourea (MNU)

INDIRECT-ACTING CARCINOGENS

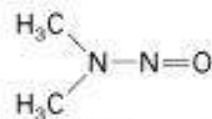

**Benzo(a)pyrene
(3,4-benzpyrene)**

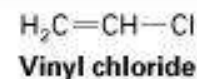

Dibenz(a,h)anthracene

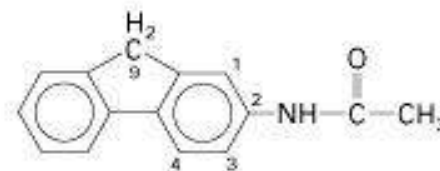

2-Naphthylamine

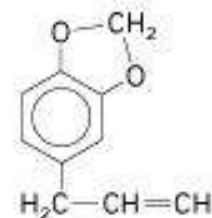

Dimethylnitrosamine

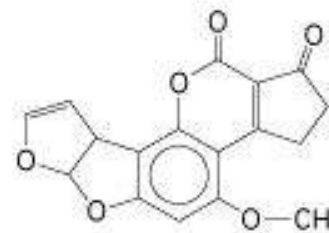

Vinyl chloride

2-Acetylaminofluorene

**Safrole
(sassafras)**

**Aflatoxin B₁
(Aspergillus flavus)**

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Types of mutation

♦ Gametic

- ⇒ occur in germ cells
 - ⇒ realise in offspring (somatic + germ cell)
 - ⇒ lead to birth effect
- ⇒ spread in the population

♦ Somatic

- ⇒ occur in somatic cells
 - ⇒ realise within the body
 - forming cancer
- ⇒ discontinue with death

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Types of mutation

Spontaneous mutations

Happen naturally, not as a result of any specific agent(s).

Replication errors or base modification as a result of chemicals (endogenous) naturally present in the cell (oxygen, acids, etc.).

Induced mutations

Mutations that result from the influence of an extraneous factor.

X-rays, UV light, chemicals not of cellular origin.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Types of mutation

Classification based on phenotypic effects

Loss of function mutation

Eliminates the function of the gene product.
Also called null mutations or gene knockouts.

Gain of function mutation

Give gene product a new function.
Generally a dominant allele.
Can give a protein a new function or cause a regulatory effect to express old protein at new time or under new conditions.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Types of mutation

Classification based on phenotypic effects

Nutritional or biochemical effect

Microbial auxotrophs.

Behavioral mutation

Mating behavior or circadian rhythms.

Regulatory mutation

E. coli lac operon operator/promoter region.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Types of mutation

Classification based on phenotypic effects

Lethal mutation

Loss of essential function.

Conditional mutation

Temperature sensitive mutations.

Neutral mutations

Commonly occur in non-gene portion of genome and have no effect on gene product/function, not selected for or against.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

POINT MUTATION

I. A single base change

1. Transition

Purine or pyrimidine is replaced by the other.

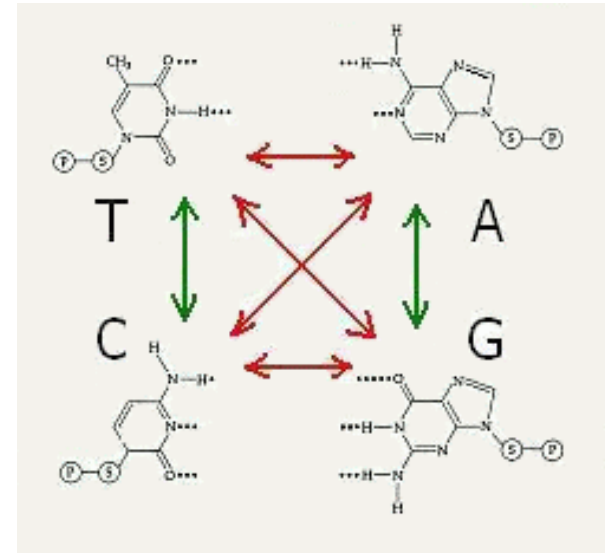

$A \leftrightarrow G$; $T \leftrightarrow C$

2. Transversion

A purine is replaced by a pyrimidine or vice verse.

$A \leftrightarrow T$ or C $T \leftrightarrow A$ or G

$G \leftrightarrow T$ or C $C \leftrightarrow A$ or G

Effects of a point mutation

The sites

- Noncoding DNA
- Nonregulatory DNA
- 3rd position of a codon

Types

Silent mutation

Phenotypic effects

No

Coding DNA → altered AA

Missense mutation

Yes or No

Coding DNA → stop codon
→ truncated protein

Nonsense mutation

Yes

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

CHROMOSOMAL ABERRATIONS

2. Numerical aberrations

⇒ (euploid – $2n$) set multiplication
⇒ poliploidy ($3n, 4n, \dots$)

⇒ aneuploidy
euploid set $\uparrow \downarrow$ with few chromosome

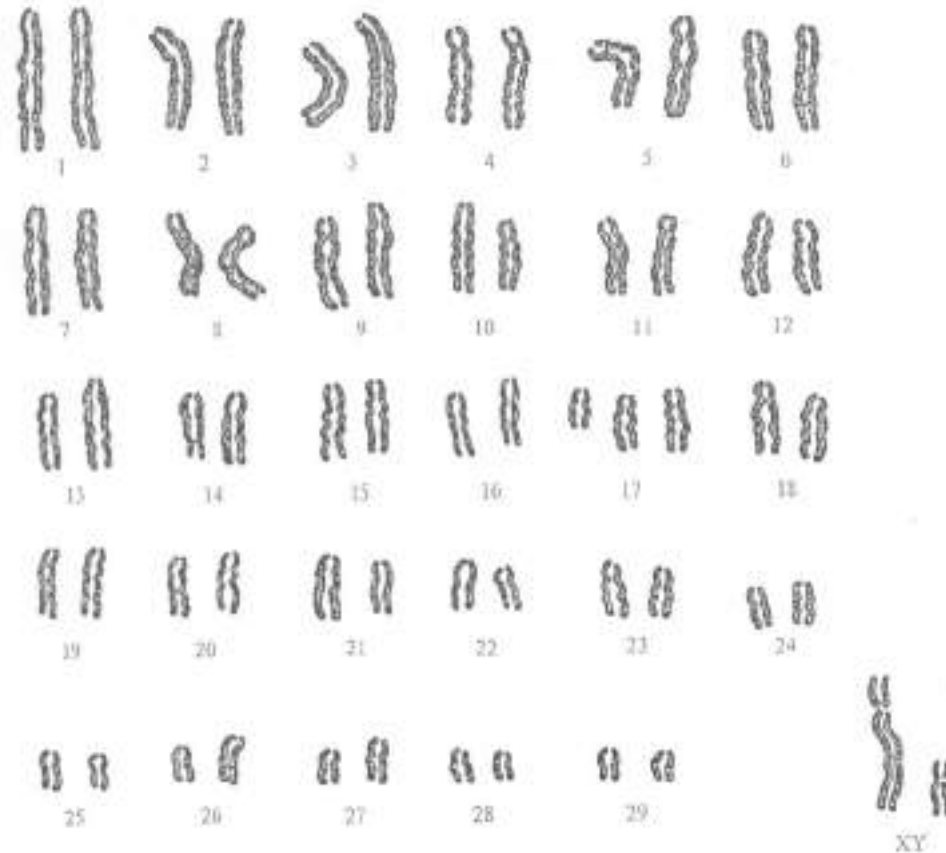

nullisomy ($2n-2$)	monosomy ($2n-1$)
trisomy ($2n+1$)	tetrasomy ($2n+2$)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Numerical chromosomal aberration (trisomy $2n+1$)

MUTAGENESIS

It is the molecular process in which the mutation is generated, including direct and indirect mutagenesis.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

MECHANIM OF ACTION

DIRECT (reactive agents directly react with DNA)

- ♦ alkylating
- ♦ deamination
- ♦ base analogs
- ♦ hydroxylation of base
- ♦ tautomeric shifts
- ♦ bulky adducts
- ♦ intercalations
- ♦ breaking of DNA (X-rays, radioactive radiation)
- ♦ thymine dimer formation

INDIRECT (damage indirectly by different mechanism)

- ♦ damaging of cell defense against superoxide radicals
- ♦ peroxisome proliferators
- ♦ modification of protein/nucleic acid synthesis (base analogs)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Direct mutagenesis

1. Alkylating

Alkylating agents are electrophilic chemicals which readily add alkyl (e.g. methyl) groups to various positions on nucleic acids.

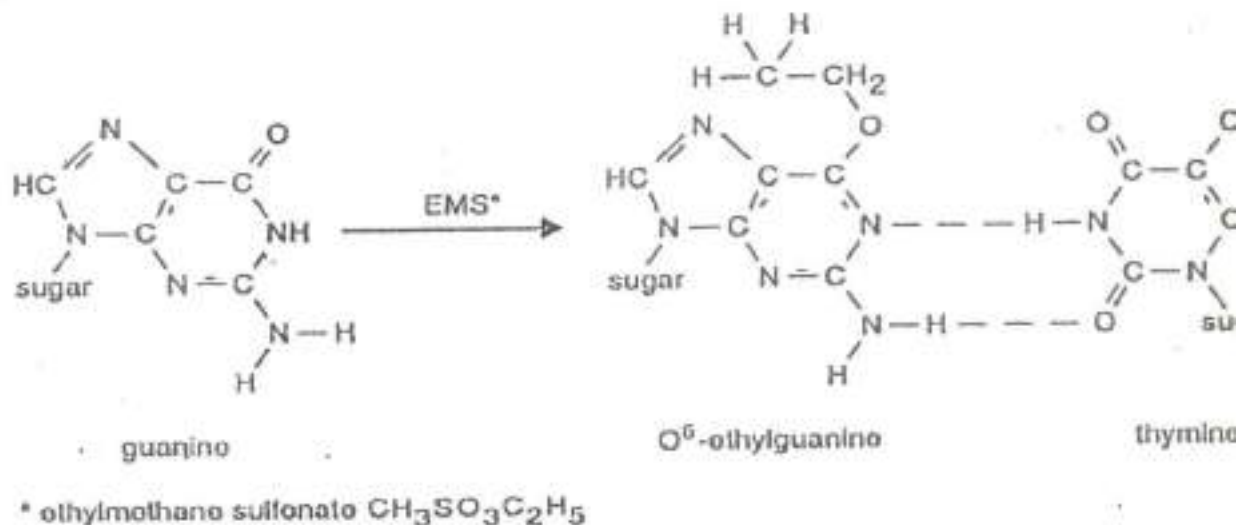

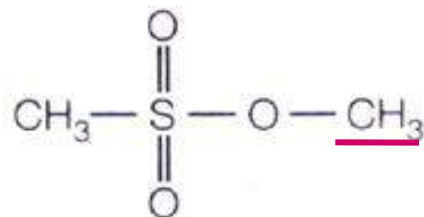

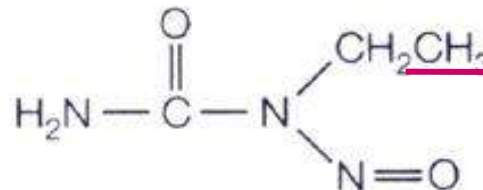

FIGURE 11.8

5-BU (keto form)

Adenine

5-BU (enol form)

Guanine

Direct mutagenesis

4. Hydroxylation of base

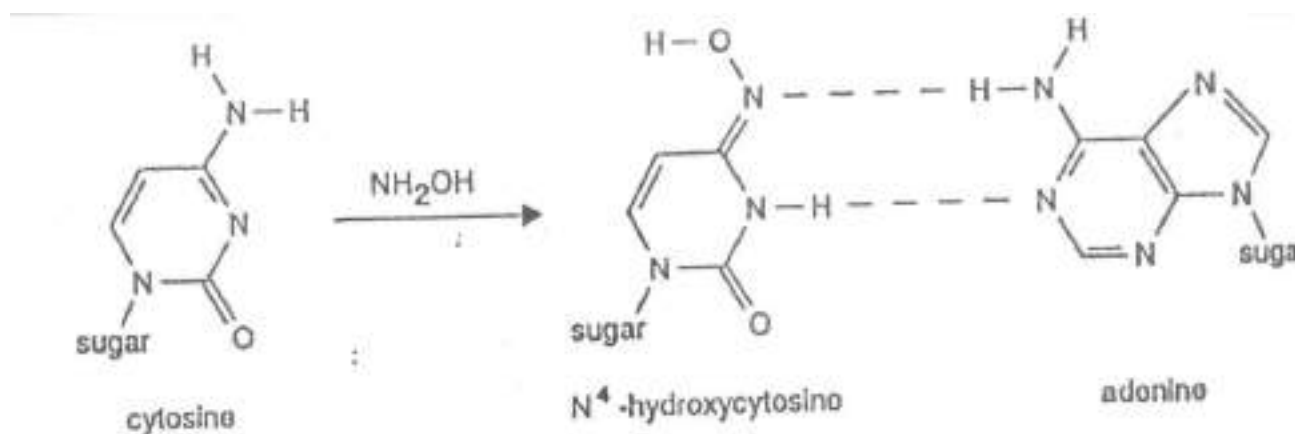

FIGURE 11.6
Chemical modification of a base (cytosine) by hydroxylamine

Direct mutagenesis

5. Tautomeric shifts

All of the bases in DNA can exist in one of several forms, called tautomer, which are isomers that differ in the positions of their atoms and in the bonds between the atoms. The keto form is normally found in DNA. The enol forms of the bases are rare. The complementary base pairing of the enols is different from that of the keto forms (e.g. hidroxilamin).

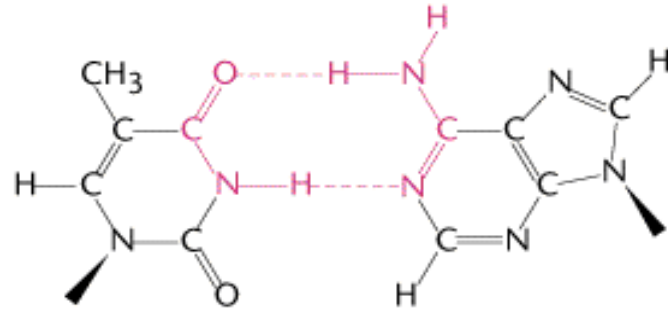

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

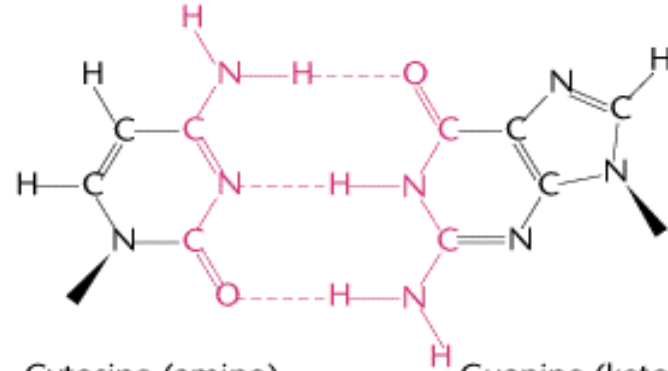

Mispairing due to tautomeric shifts

(a) Standard base-pairing arrangements

Thymine (keto)

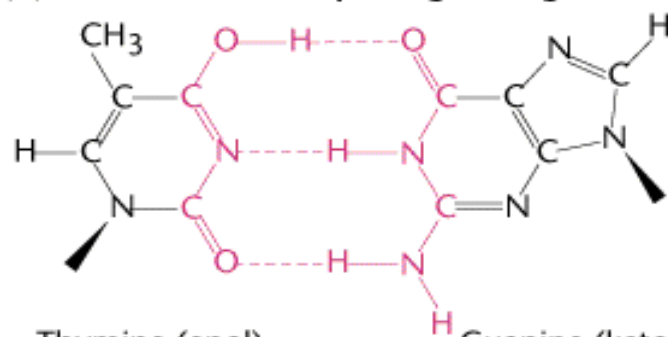

Adenine (amino)

Cytosine (amino)

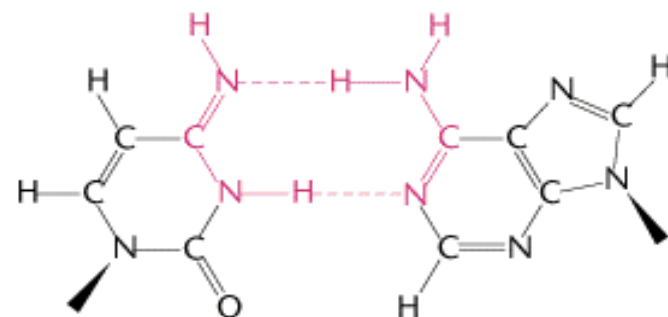

Guanine (keto)

(b) Anomalous base-pairing arrangements

Thymine (enol)

Guanine (keto)

Cytosine (imino)

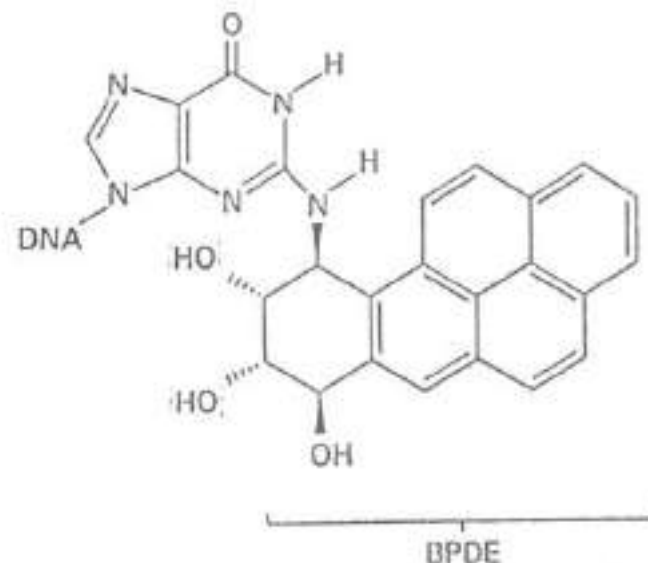

Adenine (amino)

Direct mutagenesis

6. Bulky adducts

e.g. PAH (covalent adduct)

A kind of DNA lesions that distort the double helix and cause localized denaturation. These lesions disrupt the normal function of the DNA.

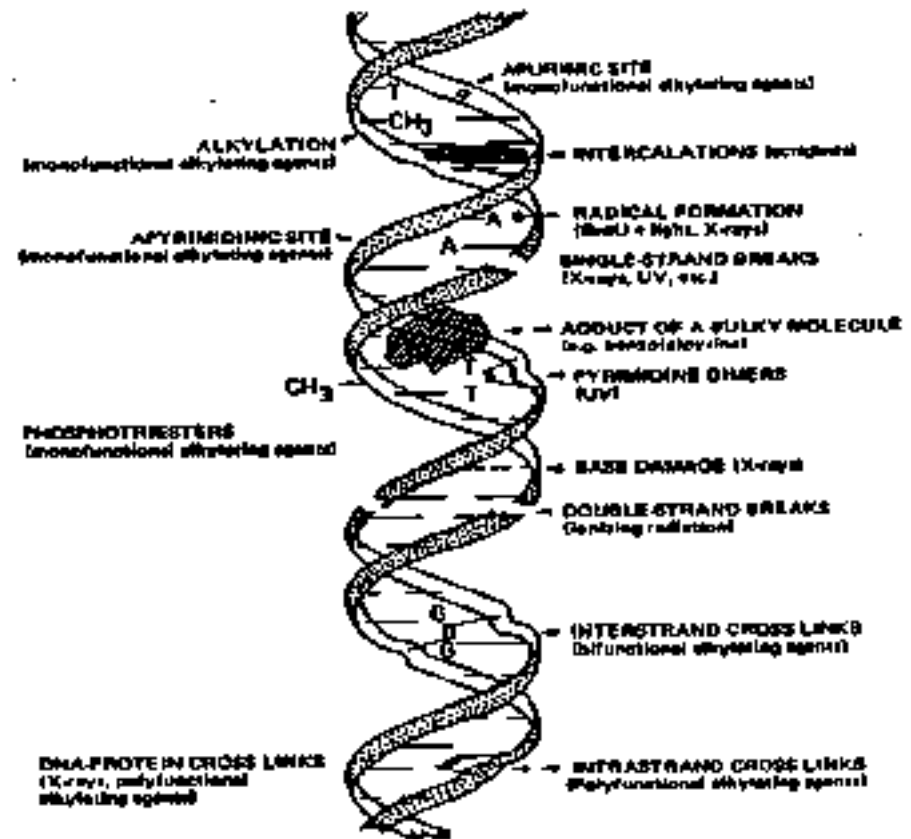

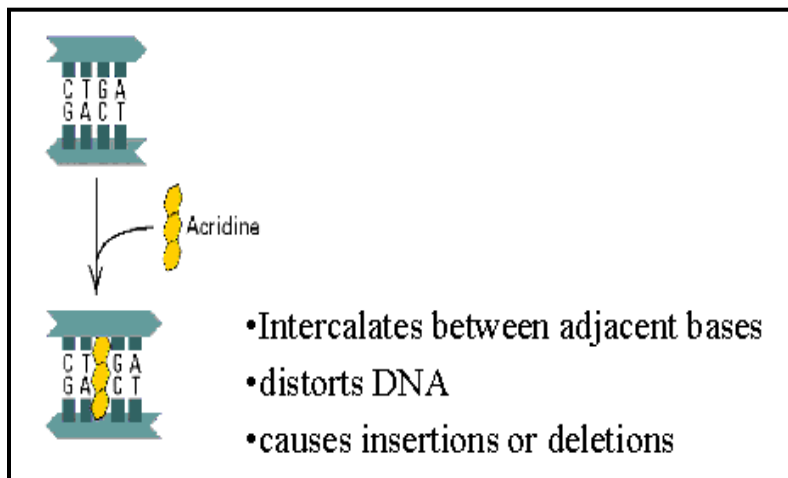

Direct mutagenesis

7. Intercalations

e.g. acridines

8. Strand breaks

e.g. ionizing radiation

Direct mutagenesis

9. Thymine dimer formation

e.g. UV radiation (260 nanometer wavelength)

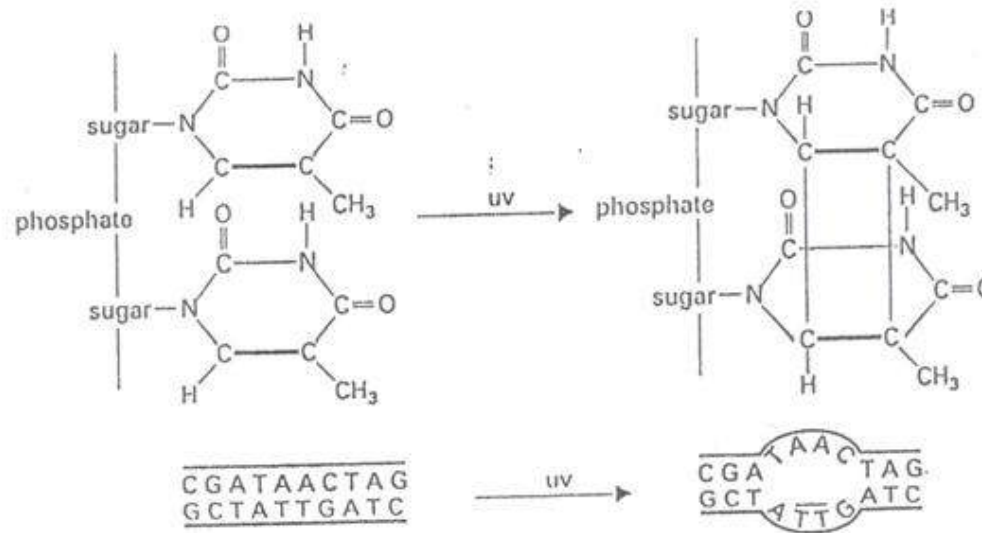

FIGURE 11.19
Structure of a thymidine dimer (upper part) and disturbance of the DNA helix (lower part) as a result of the presence of a dimer

Indirect mutagenesis

1. Damaging of cell defense against superoxide radicals

- inhibition of superoxide dismutase (e.g. dithiocarbamate fungicides)

2. Peroxisome proliferators

- peroxisome→lipid metabolism→free radicals→DNA damage (e.g. chlorophenoxy-acetic-acid herbicides)

3. Modification of protein/nucleic acid synthesis

- inhibition of ribonucleotide reductase e.g. hydroxyurea
- thymine (+)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Consequences of mutagenesis

- ♦ Numerical changes

 - ⇒ intrauterine death

- ♦ Structural changes

 - ⇒ depend on part of chromosome
 - reduced function
 - function loss
 - appearance of a new property

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Consequences of mutagenesis

DNA REPAIR MECHANISMS

DNA repair mechanisms can be classified into different categories based on the way of operation.

- Direct correction or direct reversal- reversing the damage.
- Excise the damaged areas and then repair the gap by new DNA synthesis.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

DNA repair mechanisms

I. Repairing of DNA damage before replication

1. Direct correction

a. Photoreactivation repair

Photolyase enzyme can split thymidine dimers: breaks the covalent bond.

b. Alkyltransferases

Alkylation is repaired by enzymatic transfer of methyl group by Methyl Guanine-DNA MethylTransferase.

TÁMOP-4.1.2.A/2-10/1-2010-0012

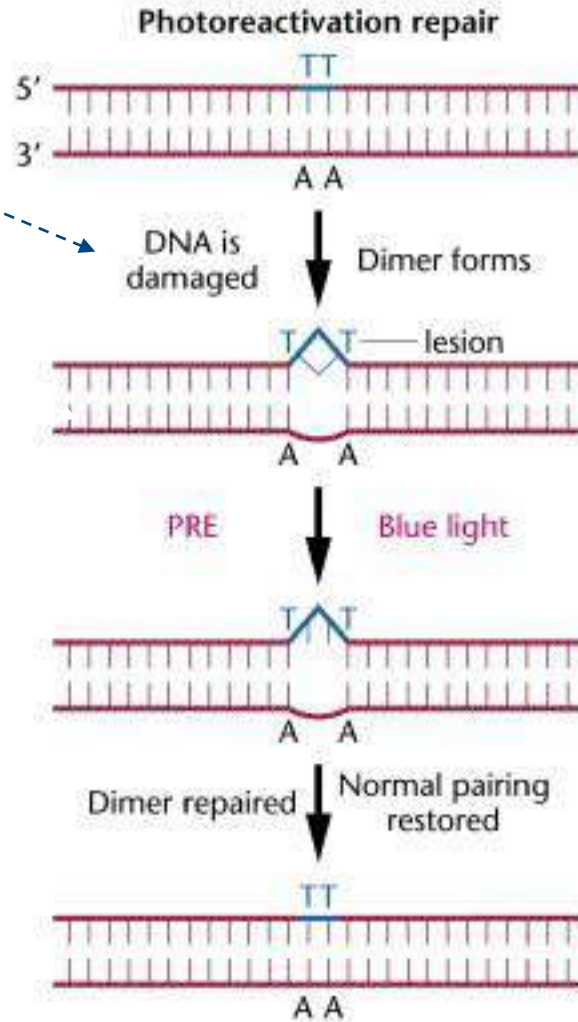

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Mutagenicity

UV

Photoreactivation
Enzyme Cleaves
bond between TT's

Visible light

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

I. Repairing of DNA damage before replication

1. Direct correction

c. N-glycosylase

Hypoxanthine product of adenine deamination is recognized, removed by hypoxanthine N-glycosylase then replaced by adenine.

d. Ligase

Simple breaks (by ionizing radiation) in one strand are repaired by DNA ligase. DNA ligase joins the DNA segments.

e. Cyclase

Close the opened ring (ring opens by ionizing radiation).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

2. Excise the damaged areas and then repair the gap by new DNA synthesis

a. Base excision repair

Repair glycosylase enzyme recognizes the damaged base and removes it, the baseless-sugar is then excised, the gap is filled by a repair DNA pol and ligase.

b. Nucleotide excision repair

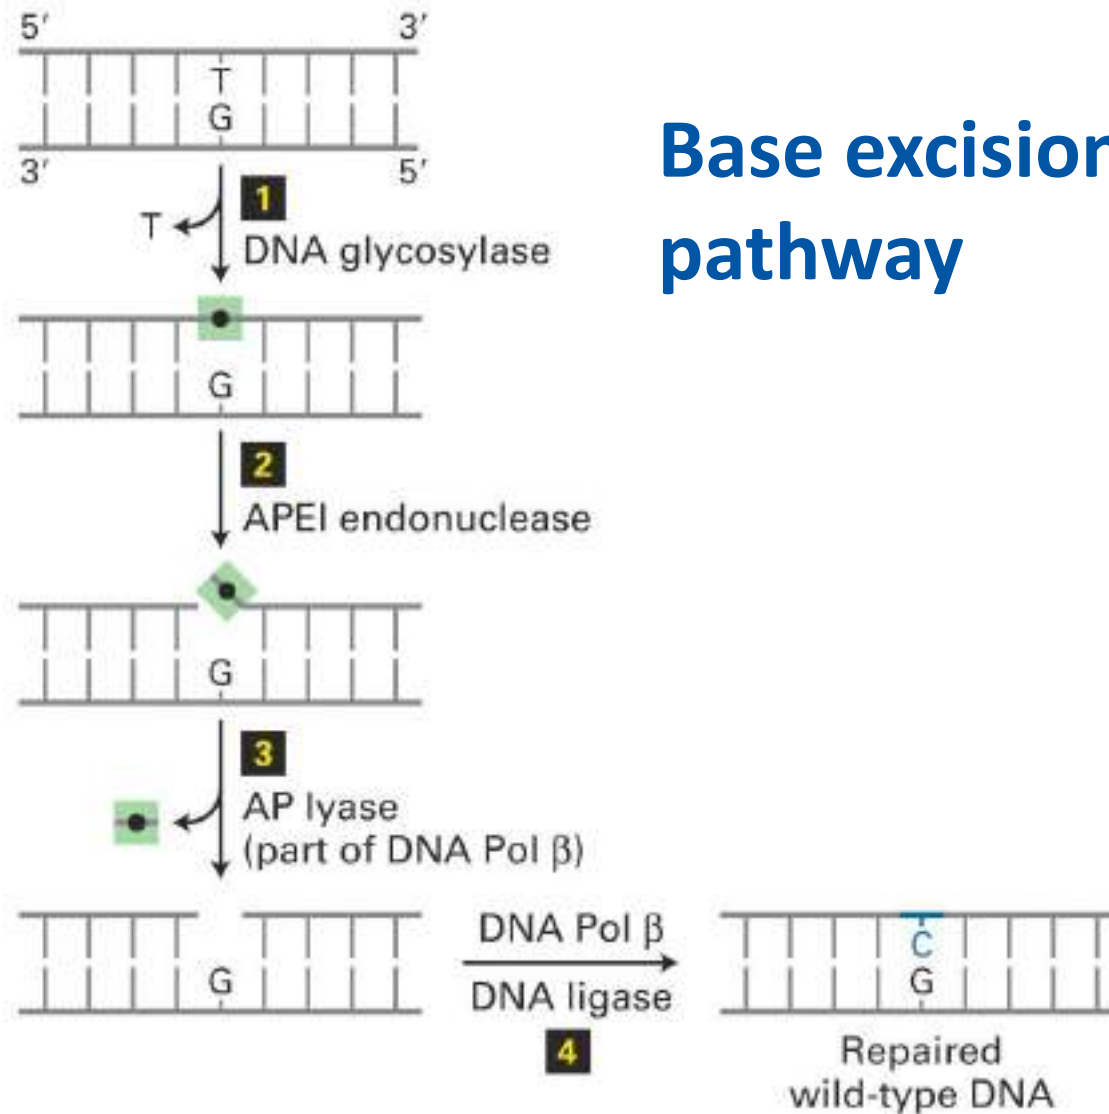

Excision Repair (dark repair or nucleotide excision repair – NER)-not photoactivated, repairs thymidine dimers and other distortions in the DNA.

TÁMOP-4.1.2.A/2-10/1-2010-0012

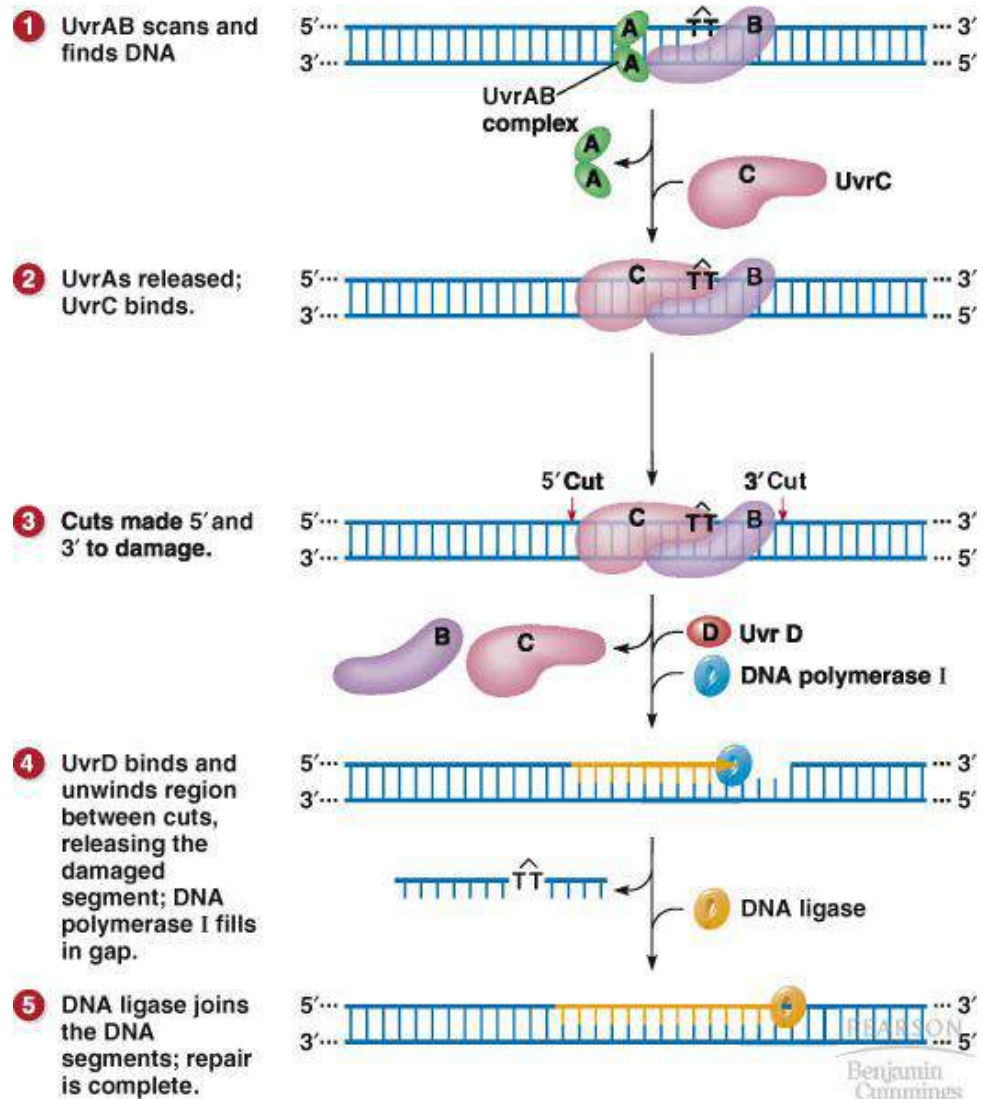

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Base excision repair pathway

Mutagenicity

Nucleotide excision repair (NER) of thymidine dimer and other damage induced distortions of DNA.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

II. Repairing of DNA damage during replication

1. Bypass repair

e.g. SOS repair

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

SOS repair

Level of DNA damage exceeds ability of normal repair systems to rapidly correct.

RecA cleaves LexA and the SOS induction occurs (also induces any prophage).

“Method of last resort”.

Involves “error-prone” DNA synthesis as site of mutation.

Generally used to fill in gaps opposite lesions over which a replication fork has passed.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

III. Repairing of DNA damage after replication

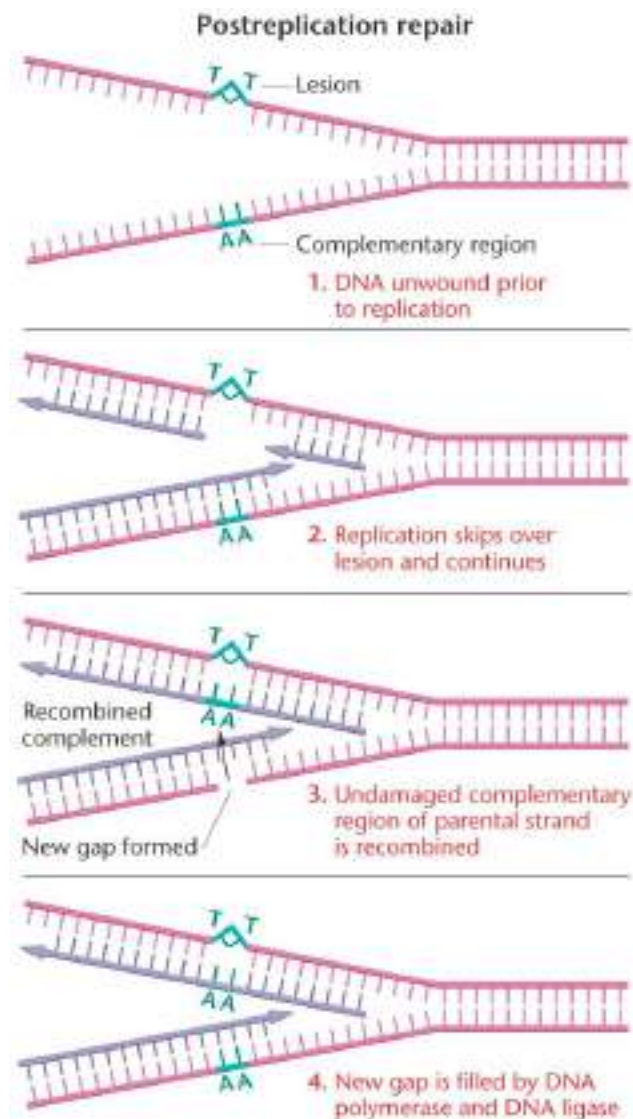

1. Recombination repair
2. Copy choice repair
3. Gap filling repair

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Mutagenicity

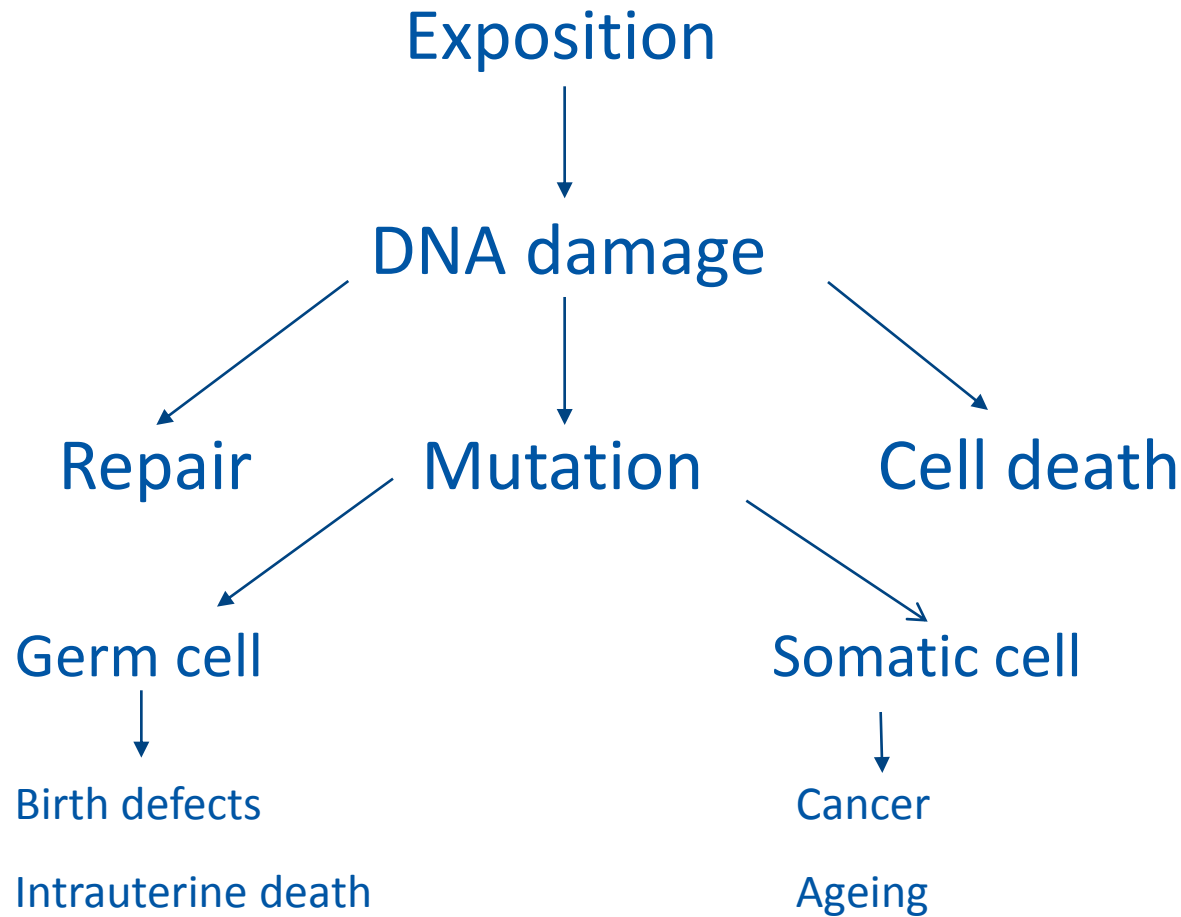

Copyright © 2006 Pearson Prentice Hall, Inc.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Final consequences of genotoxic effect

Neoplasia – „new growth”

Neoplasia

It is an abnormality of cell growth.

Cancer – „crab”

Carcinogen

A carcinogen is an agent that can cause cancer or shorten the process of tumor development.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

THEORY

One-stage process

- moment-like change of one DNA
- Cohnheim – disconnection
- Virchow – irritation

Multi-stage process

- result of more changes
- mutation of oncogen
- damaging of suppressor (inhibitor) gene

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Oncogenes

Oncogenes are cellular genes that normally stimulates cell growth and proliferation.

An oncogene is a gene that when mutated or expressed at abnormally-high levels contributes to converting a normal cell into a cancer cell.

Tumor suppressor genes

Tumor suppressor genes are cellular genes that normally suppress cell growth and proliferation.

If tumor suppressor genes were mutated or inactivated it will lead to cell transformation → cancer

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogenicity

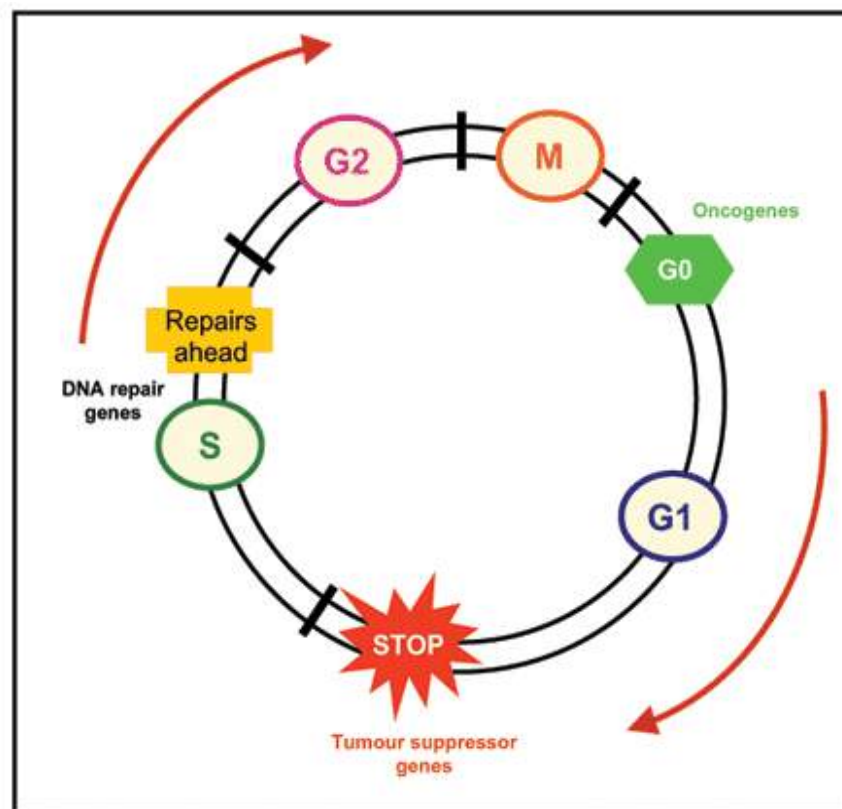

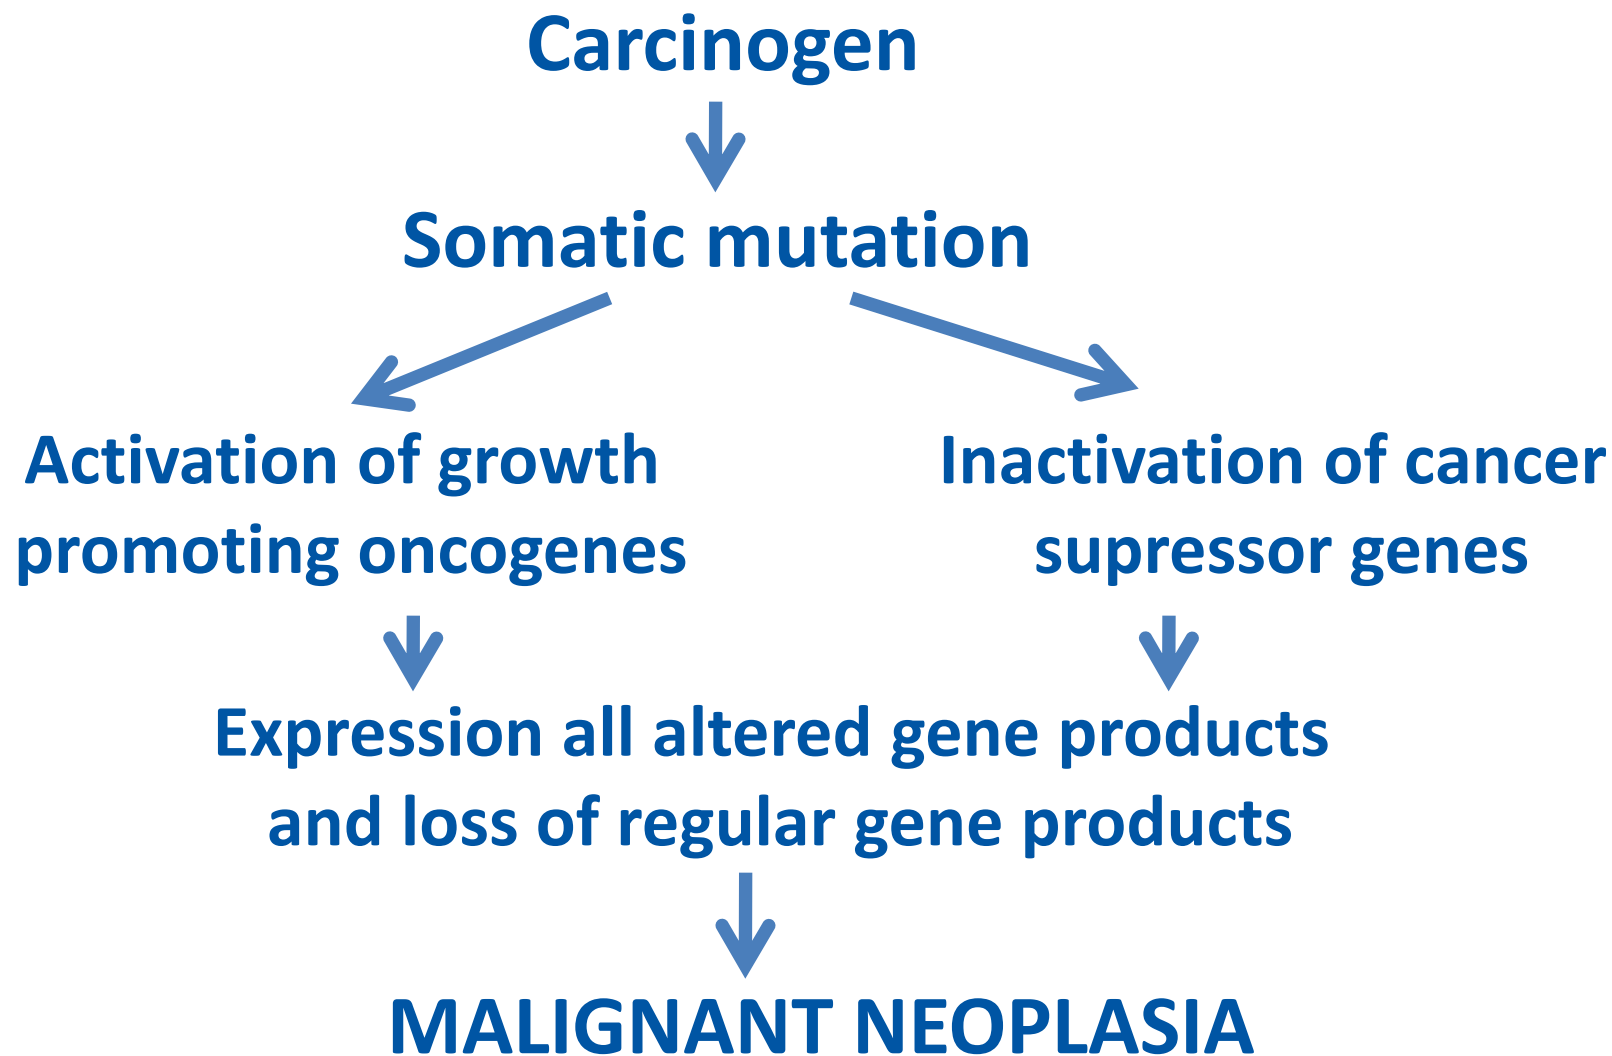

Fig. 6 – Cell cycle and its control by molecular targets (oncogenes and tumour suppressor genes). The cell cycle is a critical process that a cell undergoes in order to copy itself exactly. Most cancers cause mutations in the signals that regulate a cell's cycle of growth and division, namely in oncogenes (which act as dominant mutations) and tumour suppressor genes (that function recessively). Normal cell division is required for the generation of new cells during development and for the replacement of old cells as they die. In normal cells, tumour suppressor genes act as braking signals during G1 to stop or slow the cell cycle before it reaches the S phase. DNA repair genes are active throughout the cell cycle, particularly during G2 after DNA replication and before the chromosomes prepare for mitosis.

Phases of mechanism

Initiation

- binding covalently to DNA (adducts)
- change in the genetic material of the cell
- stabilization of mutation

Promotion

- changing in cell function
- proliferation of tumor cell
- increasing cancer

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Phases of mechanism

Progression

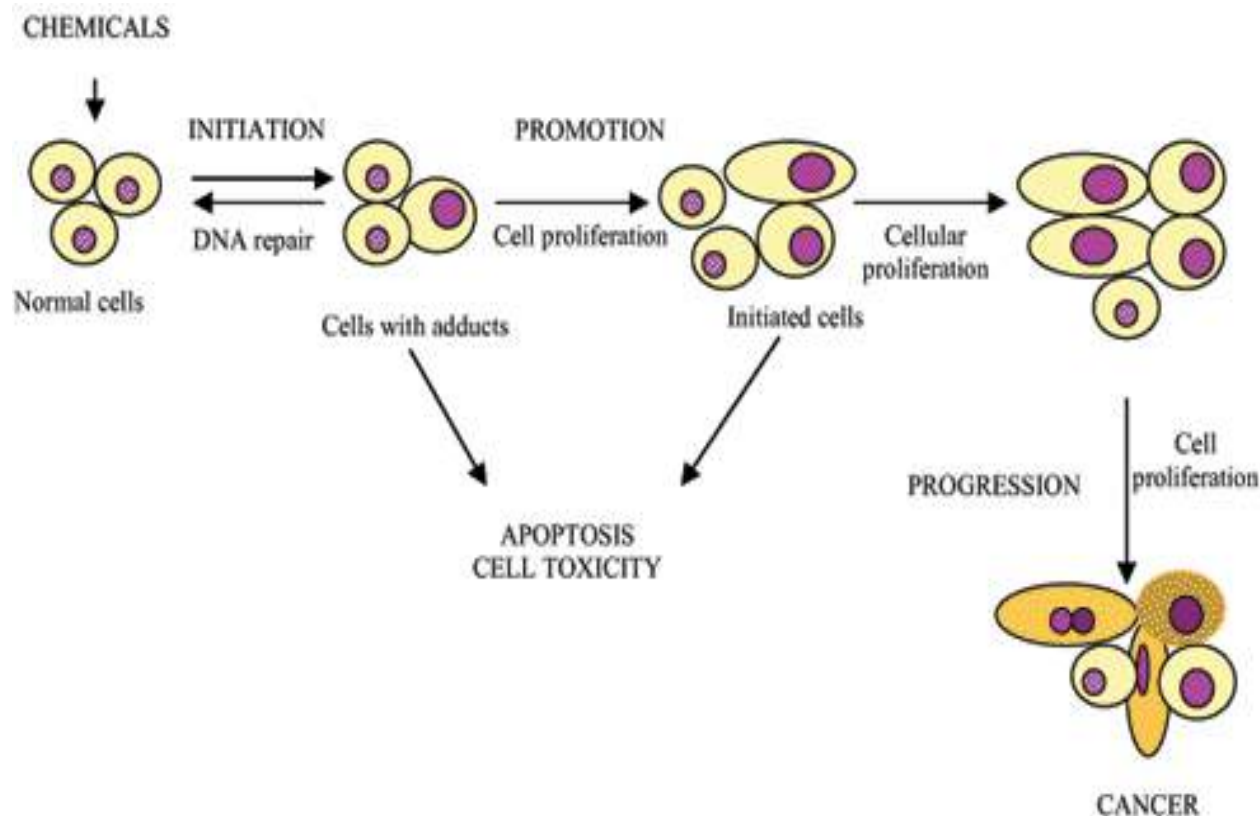

- irreversible tumour
- grow rapidly without restraint
- showing metastases
- become malignant

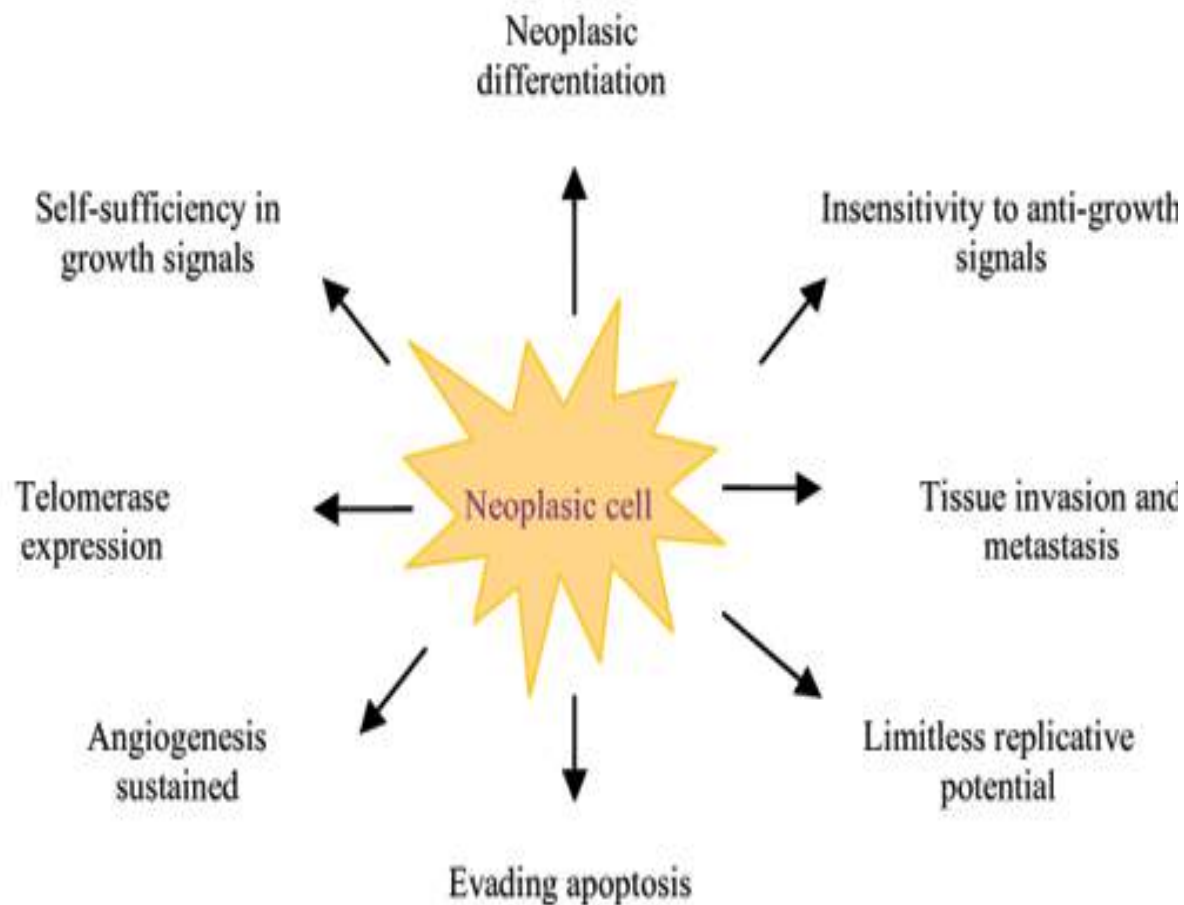

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Phases of mechanism

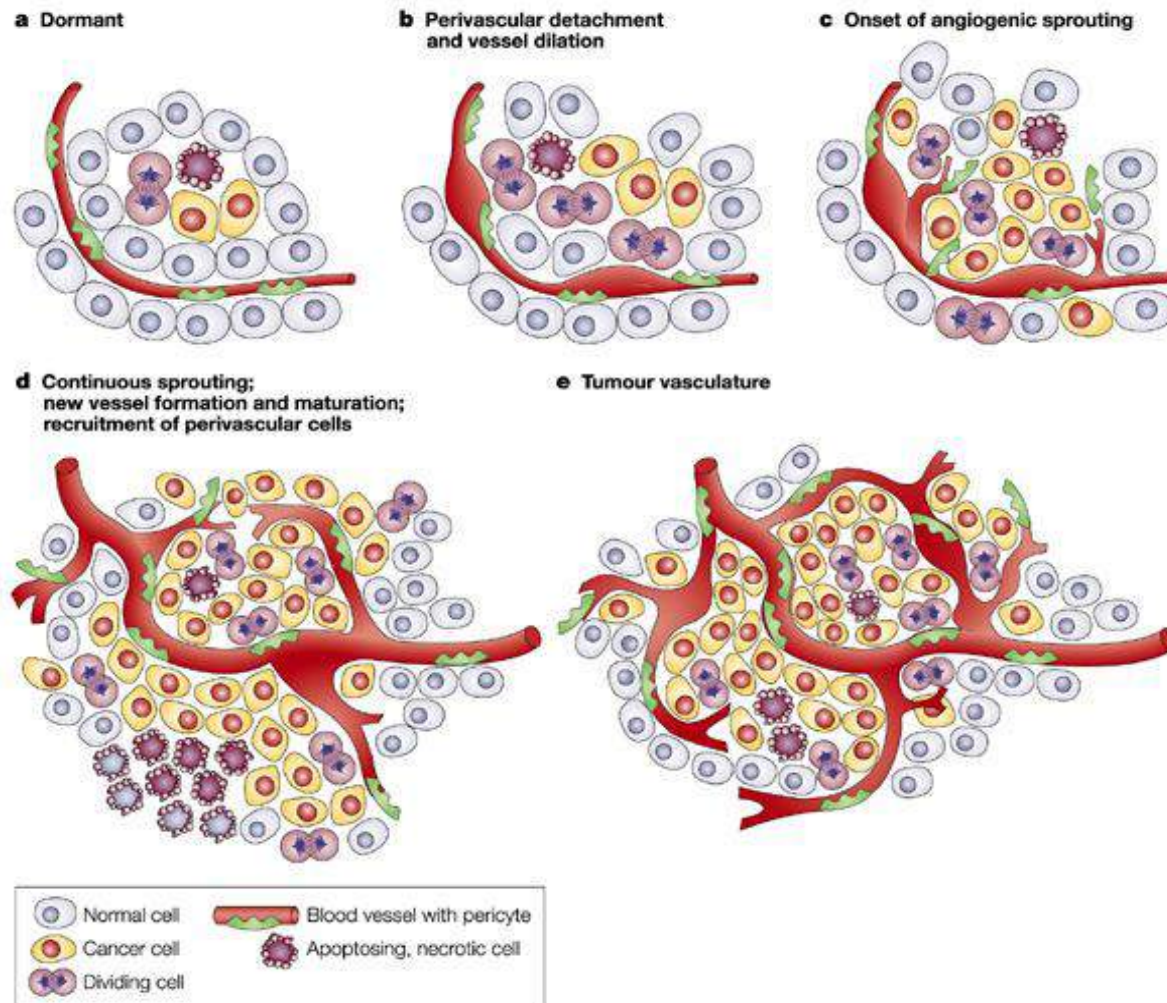

Carcinogenicity

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Angiogenesis

Prognosis

Benign tumour

- slow growth
 - Ø infiltrative, encapsulated
 - Ø form metastases
- ⇒ can usually be removed surgically

Malign tumour

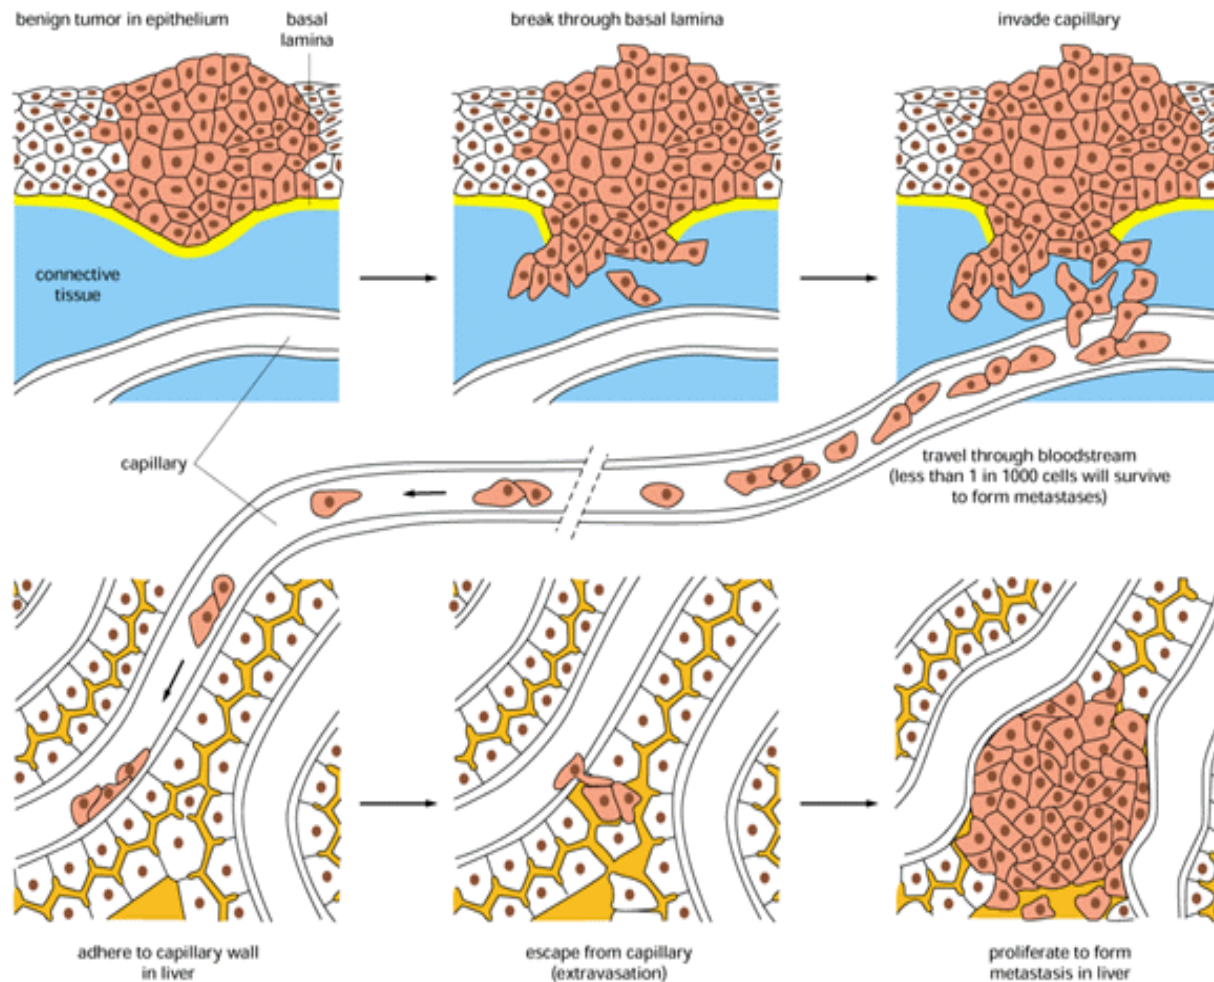

- ability to multiple rapidly
 - invade neighboring tissues
 - forming metastases
- ⇒ difficult to remove surgically

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Metastasis

Type of Carcinogen

Genotoxic carcinogen

Direct biological capacity to damage DNA

- direct-acting – parent molecule (alkylating agent)
- activation-dependent (PAH, nitrosamines)

Properties

- hereditary change
- irreversible effect
- restricted dose-dependent
- \emptyset threshold dose

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogenicity

Type of Carcinogen

Epigenetic carcinogen

Ø direct damage DNA

Operate indirectly by a variety of mechanism

- inhibition of nucleic acid synthesis
- inhibition of mitosis
- immunosuppression

Properties

- reversible effect
- dose-dependent
- threshold dose

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogenic agents

Physical

- ionizing radiation (leukaemia)
- UV radiation (skin)
- asbestos (lungs)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogenic agents

Chemical

- As, Cd, Ni
- Rd
- PAH
- vinyl chloride
- benzene
- rubber manufacturing
- conversion of timber
- paint manufacturing

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogenicity

TABLE II
Chemical carcinogens.

Group	Compound	Mechanism of action	Affected organs/ Cancer type
Polycyclic aromatic hydrocarbons	Benzo[a]pyrene Polychlorinated biphenyls (Luch 2005)	Form adducts with purine bases of DNA, mainly resulting on transversions	Skin, lungs, stomach Liver skin
Aromatic amines/amides	2-Acetylaminofluorene 4-Aminobiphenyl 2-Naphthylamine (Luch 2005)	Genotoxic compounds, increase the rate of cell duplication	Liver, bladder Bladder Bladder
Aminoazo dyes	o-Aminoazotoluene <i>N, N</i> -dimethyl-4-aminoazobenzene (Golka et al. 2004)	Forms adducts with DNA and with haemoglobin	Liver, lungs, bladder Lungs, liver
N-nitroso compounds	N-Nitrosodimethylamine (Drablos et al. 1998)	Form adducts at N- and O-atoms in DNA bases	Liver, lungs, kidneys
Carbamates	N-methylcarbamate esters (Wang et al. 1998)	Chromosome aberration, gene mutation, cell transformation	Experimental results showed liver, kidneys and tests degeneration
Halogenated compounds	Trichloroethylene (Lock et al. 2007)	Somatic mutations, modification of cell cycle pathways	Experimental results showed kidney, liver and lung cancer
Natural carcinogens	Aflatoxin B1 (Wild et al. 1986) Asbestos (Luch 2005)	Forms adducts with guanine, react with RNA and proteins	Liver Lungs
Metals	Arsenic (Shi et al. 2004) Cadmium (Hartwig et al. 2002) Nickel (Costa et al. 2003)	Oxidative stress Inhibit DNA repair pathways and nucleotide-excision repair Histone acetylation and DNA hypermethylation	Skin, lungs, liver Lungs, prostate, kidneys Lungs, nasal cavity
Anticancer drugs	Alkylating agents (Luch 2005)	Interstrand and/or intrastrand cross-links	Leukaemia

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogenic agents

Biological

- parasites: *Schistosoma haematobium*
Clonorchis sinensis
- viruses: *HTLV 1, HIV*
Herpes simplex 2. típ.
Eppstein-Barr, Hepatitis B
Human Papilloma
- bacteria: *Helicobacter pylori*

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogen Risk Assessment

MAK Commission	TLV Commission	IARC	European Union
A1 Human carcinogen	A1 Confirmed human carcinogen	1 Carcinogenic to humans	1 Carcinogenic to humans
A2 Animal carcinogen	A2 Suspected human carcinogen	2a Probably carcinogenic to humans	2 Should be regarded as if carcinogenic to humans
	A3 Animal carcinogen		
B Substances suspected of having carcinogenic potential		2b Possibly carcinogenic to humans	3 Cause concern for humans
			3a Well investigated
	A4 Not classifiable as human carcinogen	3 Not classifiable as human carcinogen	3b Insufficiently investigated
	A5 Not suspected as a human carcinogen	4 Probably not carcinogenic	

TÁMOP-4.1.2.A/2-10/1-2010-0012

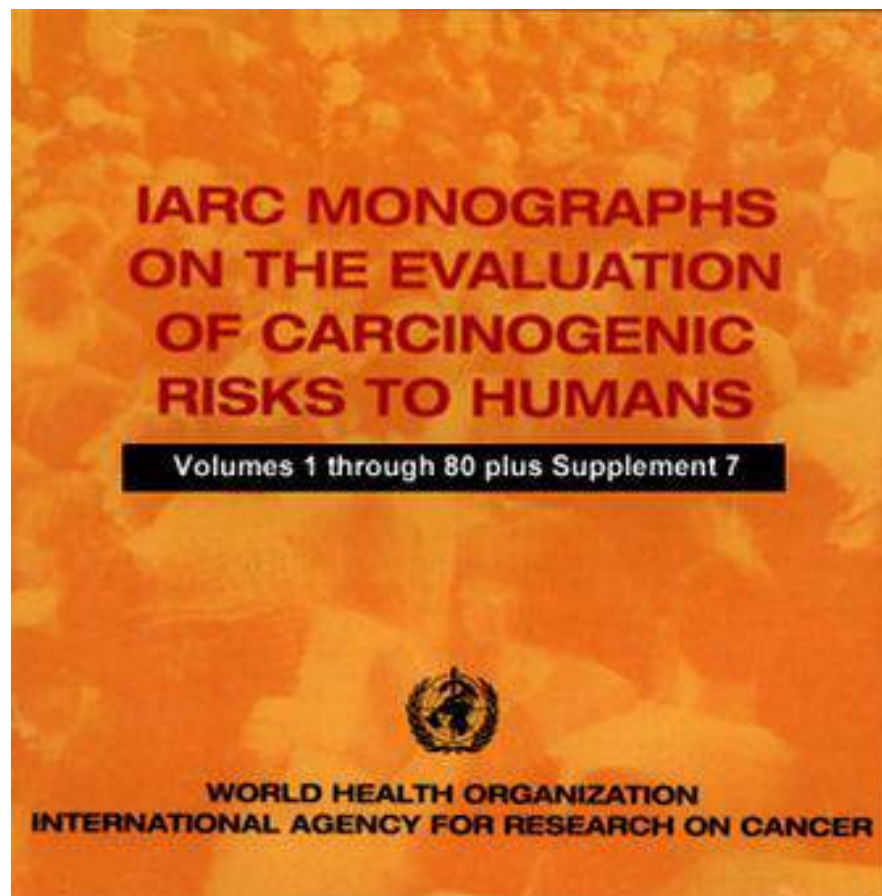

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogen Risk Assessment

International Agency for
Research on Cancer (IARC)

Centre International de
Recherche sur le Cancer (CIRC)

IARC, 150 Cours Albert Thomas, 69372 Lyon CEDEX 08, France
Tel: +33 (0)4 72 73 84 85 - Fax: +33 (0)4 72 73 85 75

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogen Risk Assessment

Group 1 — The agent is carcinogenic to humans.

- sufficient evidence of carcinogenicity in humans
- sufficient evidence of carcinogenicity in experimental animals

Group 2A — The agent is probably carcinogenic to humans.

- limited evidence of carcinogenicity in humans
- sufficient evidence of carcinogenicity in experimental animals

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogen Risk Assessment

Group 2B — The agent is possibly carcinogenic to humans.

- limited evidence of carcinogenicity in humans
- less than sufficient evidence of carcinogenicity in experimental animals

Group 3 — The agent is not classifiable as to its carcinogenicity to humans.

- evidence of carcinogenicity is inadequate in humans
- inadequate or limited evidence of carcinogenicity in experimental animals

Group 4 — The agent is probably not carcinogenic to humans.

- evidence suggesting lack of carcinogenicity in humans and in experimental animals

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dysfunctions of the immune system

- inhibition → immunosuppressive effect
PAH, heavy metals, alkylating agents,
organophosphates
- stimulation → hypersensitivity

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

➤ The mechanism of allergy induced by chemicals

- ♦ Independent of the dose
- ♦ First meeting with chemical agent
 - chemical agent (hapten) + protein binding
 - ⇒ antibody production (7-14 days)
- ♦ Repeated meeting with chemical agent
 - chemical agent + antibody
 - ⇒ allergic reactions
 - hives, dermatitis, oedema, breathing problems

Allergic chemicals

drugs (e.g. salicylates), pesticides

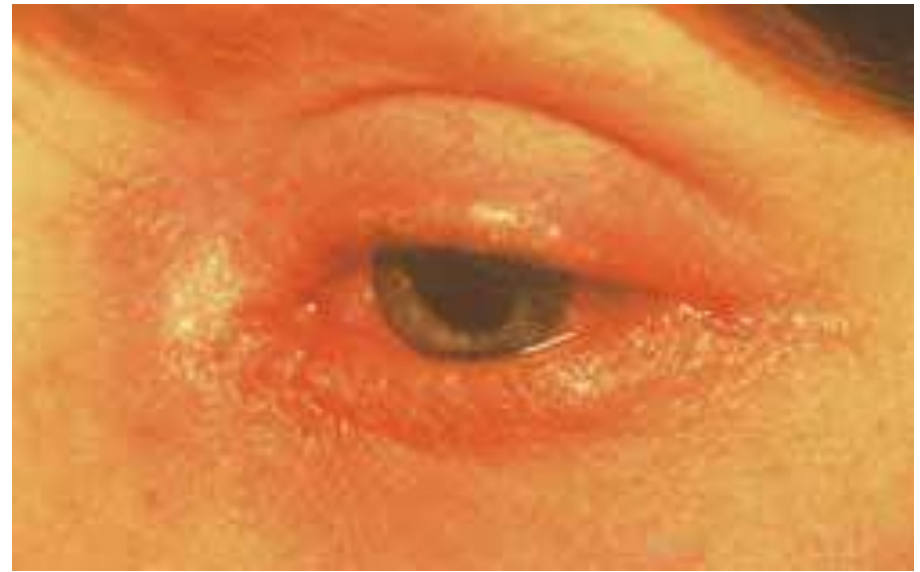

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Allergy induced by chemicals

Normal larynx

Laryngeal oedema

Main topics

- Brief history of toxicology
- Basic terms of toxicology
- Dose-response relationships
- Toxicodynamic effects
- Toxicokinetics
- Factors influencing toxicity
- Teratogenicity
- Mutagenicity
- Carcinogenicity
- Allergy induced by chemicals

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

History of toxicology = history of the human race

The early humans must have learnt to discriminate between things that were good to eat and those that were not

Natural progression → hunting
warfare
homicide

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

- Arrow poisons were developed by ancient peoples in all parts of the world, and many are still in use (Masai hunters – 18000 years ago).

Phylllobates terribilis

Diamphidia nigro-ornata (Bushman arrow-poison beetle)

Strychnos toxifera

Brief history of toxicology

Ebers Papyrus (~1500 B.C.)

- The oldest well preserved medical document
- Contains 110 pages on anatomy and physiology, toxicology, spells, and treatment recorded
- More than 800 medicinal and poisonous recipes, many contain recognized poisons (opium, hemlock, lead...)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Socrates (470-399 B.C.)

He was found guilty of corrupting the minds of the youth of Athens and sentenced to death by drinking a mixture containing poison hemlock.

Brief history of toxicology

Cleopatra – Queen of Egypt (69-30 B.C.)

Experimented with strychnine and other poisons on prisoners and poor. Committed suicide with Egyptian Asp (Egyptian cobra sometimes used in executions).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dioscorides (40-90 A.D.)

Greek physician who classified poisons for Nero. Wrote the *Materia Medica* (5 volumes) documenting over 600 medicinal plants he encountered while traveling with the Roman military, as well as earlier compilations of Roman and Greek knowledge.

This was a standard text for 16 centuries!

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

Swiss physician Paracelsus (1493-1541) credited with being **“the father of modern toxicology.”**

“All substances are poisons: there is none which is not a poison. The right dose differentiates a poison from a remedy.”

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Befektetés a jövőbe

Catherine Medici (1519-1589)

She often used poisoning as a political tool during her reign.
She experimented with poisons on the sick and poor to develop more advanced poisons.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

Mathieu Orfila (1787 - 1853)

Established a systematic correlation between the chemical and biological properties of poisons.

He demonstrated effects of poisons on specific organs by analyzing autopsy materials for poisons and their associated tissue damage.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

20th Century

Chemical Warfare (1915)

By the middle of the 1910's, chemicals had been developed to be used by the military as weapons. Agents such as Chlorine, Chloropicrin, Phosgene and Mustard gas were all used in chemical warfare. Humans and dogs were fitted with gas masks.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

20th Century

Gerhard Schrader (1903-1990)

Accidentally developed the toxic nerve agents Sarin, Tabun, Soman, and Cyclosarin while attempting to develop new insecticides. As a result, these highly toxic gases were utilized during World War II by the Nazi's. He is sometimes called the "father of the nerve agents".

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

20th Century

DDT – 1939

Paul Hermann Müller

Recognized as insecticide by the Swiss scientist Paul Hermann Müller, who was awarded the 1948 Nobel Prize in Physiology and Medicine. DDT was banned in late sixties and early seventies.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Brief history of toxicology

20th Century

Rachel Carson - alarmed public about dangers of pesticides in the environment.

Human role in ecology and as well as safety from pesticides were some of the fields she worked in.

Scientist leads crusade against the use of DDT, a pesticide and persistent organic pollutant.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Basic terms of toxicology

DIFFERENT AREAS OF TOXICOLOGY

CLINICAL TOXICOLOGY

Clinical toxicologists usually are physicians or veterinarians interested in the prevention, diagnosis, and treatment of poisoning cases.

They have specialized training in emergency medicine and poison management.

EXPERIMENTAL TOXICOLOGY

Experimental toxicologists study the harmful effects of chemical substances on living animals (mechanism of action, disposition, analytical procedures).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Basic terms of toxicology

ENVIRONMENTAL TOXICOLOGY

Environmental toxicologists study the effects of pollutants on organisms, populations, ecosystems, and the biosphere.

FOOD TOXICOLOGY

Food toxicologists deal with the possible deleterious effects of chemicals in food for human consumption (residue level).

FORENSIC TOXICOLOGY

Forensic toxicologists study the application of toxicology to the law. They use chemical analysis to determine the cause and circumstances of death in a postmortem investigation.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

OTHER SPECIAL AREAS

Industrial toxicology

Occupational toxicology

Regulatory toxicology

Regulatory toxicologists use scientific data to decide how to protect humans and animals from excessive risk.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

WHAT IS TOXICOLOGY?

THE STUDY OF THE ADVERSE EFFECTS OF CHEMICAL AGENTS ON LIVING ORGANISMS.

ADVERSE EFFECTS

- any change from an organism's normal state
- dependent upon the concentration of active compound at the target site for a sufficient time

POISON = TOXICANT

- inorganic and organic lifeless substances
- any substance that causes deleterious effects in a living organism

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

POISONS

- biologic origin (nicotine, botulinum toxin)
- naturally-occurring chemical element (Pb,Cu)
- manufactured chemicals (pesticides)
- results of a physical process (CO)

“Synthetic” does not mean toxic or poisonous

“Natural” does not mean safe or even low risk

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Basic terms of toxicology

TOXIN

Poisonous substance produced by a living organism, such as a plant, animal or micro-organism

Phytotoxins
Zootoxins
Bacteriotoxins
Mycotoxins

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

XENOBIOTIC

A chemical compound that is foreign to the body or to living organisms.

(xenos-strange, bios-life)

TOXICOSIS = POISONING = INTOXICATION

Describes the disease state which results from exposure to a poison.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

TOXIC SYMPTOM

It is any feeling or sign indicating the presence of a poison in the system.

TOXIC EFFECTS

It refers to the health effects that occur due to exposure to a toxic substance.

TOXICITY

The adverse effects that a chemical may produce.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Basic terms of toxicology

EXPOSURE

The actual contact of the chemical substance with the biological organism.

(It means contact with a hazard.)

HAZARD

It is a chemical substance, physical agent, or biological agent that can harm the health of people.

The likelihood that the toxicity will be expressed.

Risk = Hazard X Exposure

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

The Dose Makes the Poison

An apparently nontoxic chemical can be toxic at high doses. (Too much of a good thing can be bad.)

Highly toxic chemicals can be life saving when given in appropriate doses. (Poisons are not harmful at a sufficiently low dose.)

Terms defining toxicity: The Median Lethal Dosage

LD₅₀

The amount (dosage) of a chemical substance that produces death in 50% of a population of test animals to which it is administered by any of a variety of methods.

mg/kg

Normally expressed as milligrams of chemical substance per kilogram of animal body weight.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose

Total amount of a chemical substance administered to an organism

Dosage

Characteristics of organism

Body weight

Surface area

Dosage is more precise (mg chemical substance/kg body weight)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Terms defining toxicity : The Median Lethal Concentration

LC₅₀

The concentration of a chemical substance that produces death in 50% of a population of test animals to which it is exposed.

mg/m³ , mg/l, mg/g(kg)

Normally expressed as milligrams of chemical substance per m³, l, g (kg) of the medium (air, water, soil...).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Basic terms of toxicology

Chemical substance	LD ₅₀ mg/kg b.w.
Ethyl alcohol	10 000.0
Sodium chloride	4 000.0
Morphin	900.0
Dithane M-45	10 700.0
Decis 2.5 EC	620.0
Temik 10 G	0.9
Nicotine	1.0
Aflatoxin B1	7.2
WX (chemical warfare)	0.015
Dioxin	0.001
Tityustoxin	0.009
Tetanus toxin	0.000002
Botulinum toxin	0.000001

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Classification of chemical substance based on toxicity

Toxicity class	LD ₅₀ mg/kg b.w.	Probable lethal oral dose for humans
Supertoxic	<5	a taste (less than 7 drops)
Extremely toxic	5-50	between 7 drops and teaspoonful
Very toxic	50-500	between teaspoonful and ounce (1/3 dl)
Moderately toxic	0.5-5 (g/kg)	a glass
Slightly toxic	5-15 (g/kg)	0.5-1 liter
Practical nontoxic	>15 (g/kg)	>1 liter

Local adverse effects

The site of action takes places at the point of contact.

The site:

- skin
- mucous membrane of the eyes, nose, mouth, throat
- or anywhere the along the respiratory or gastrointestinal system

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Systemic adverse effects

Requires absorption and distribution to a distant site.
Most chemical substances can produce systemic effects

Target organs:

CNS, circulatory system, blood and hematopoietic system, liver or GI, kidney, lung

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Cumulative Effects

Over a period of time, the material is only partially excreted and the remaining quantities are gradually collected.

The retained toxic compound accumulates and becomes great enough to cause adverse effect.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Immediate / Delayed Toxicity

Immediate

Develops rapidly after a single administration of a substance.

Delayed

Toxic effects occur after the lapse of some period of time.

Carcinogenic effects have long latency (up to 30 years).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Reversible / Irreversible Toxic Effects

Some toxic effects are reversible, and others are irreversible.

Level of tissue injury

- Liver has high regenerative ability (most are reversible)
- Central nervous system have differentiated cells (largely irreversible)
- Carcinogenic and teratogenic???

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Basic terms of toxicology

Various interactions of chemical substances

Additive

Combined effect of two chemicals is equal to the sum of the effects of each ($2+3=5$).

Synergistic

Combined effect of two chemicals are much greater than the sum ($2+2=20$).

Potentiation

One substance does not have a toxic effect on a certain organ or system but when added to another chemical is already toxic.

Antagonism

Two chemicals interfere with each others in actions.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Basic terms of toxicology

Exposure

The actual contact of the chemical substance with the biological organism.

Routes and Sites of Exposure

- Ingestion (Gastrointestinal Tract – food and water)
- Inhalation (Lungs - air)
- Dermal/Topical (Skin)
- Injection (intravenous, intramuscular, intraperitoneal...)

Typical Effectiveness of Route of Exposure

i.v. > inhale > i.p. > i.m. > ingest > topical

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Duration and Frequency of Exposure

Acute

A single exposure lasting less than 24 hours.

Subacute

Repeated exposure lasting 1 month or less.

Subchronic

Repeated exposure lasting from 1 month to 3 months.

Chronic

Repeated exposure lasting more than 3 months (over months or years).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ACUTE POISONING

The body is exposed to the toxic substance in a single high dose.

Symptoms of poisoning develop in close relation to the exposure (within hours or days).

CHRONIC POISONING

The body is exposed repeatedly to toxic substance in low dose during a long period .

Symptoms of poisoning are appeared after a long period (months or years).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose-response relationship

Paracelsus was the first to recognize the concept of dose.

Fundamental concept in toxicology.

What is a toxic response?

- Death
- Pathological lesions
- Biochemical, pharmacological, or chemical change

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose-response relationships

Individual dose-response curve

- Response of an individual to varying doses of a chemical substance
- Graded response – continuous over a range of doses

Quantal dose-response curve

- Population
- Distribution of responses to different doses in a population of individual organisms

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose-response relationships

Symptoms

Concentration of CO in the blood

- 1- headache
- 2- dizziness
- 3- nausea, vomit
- 4- unconsciousness
- 5- death

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose-response relationships

As the dose of a toxicant increases, so does the response.

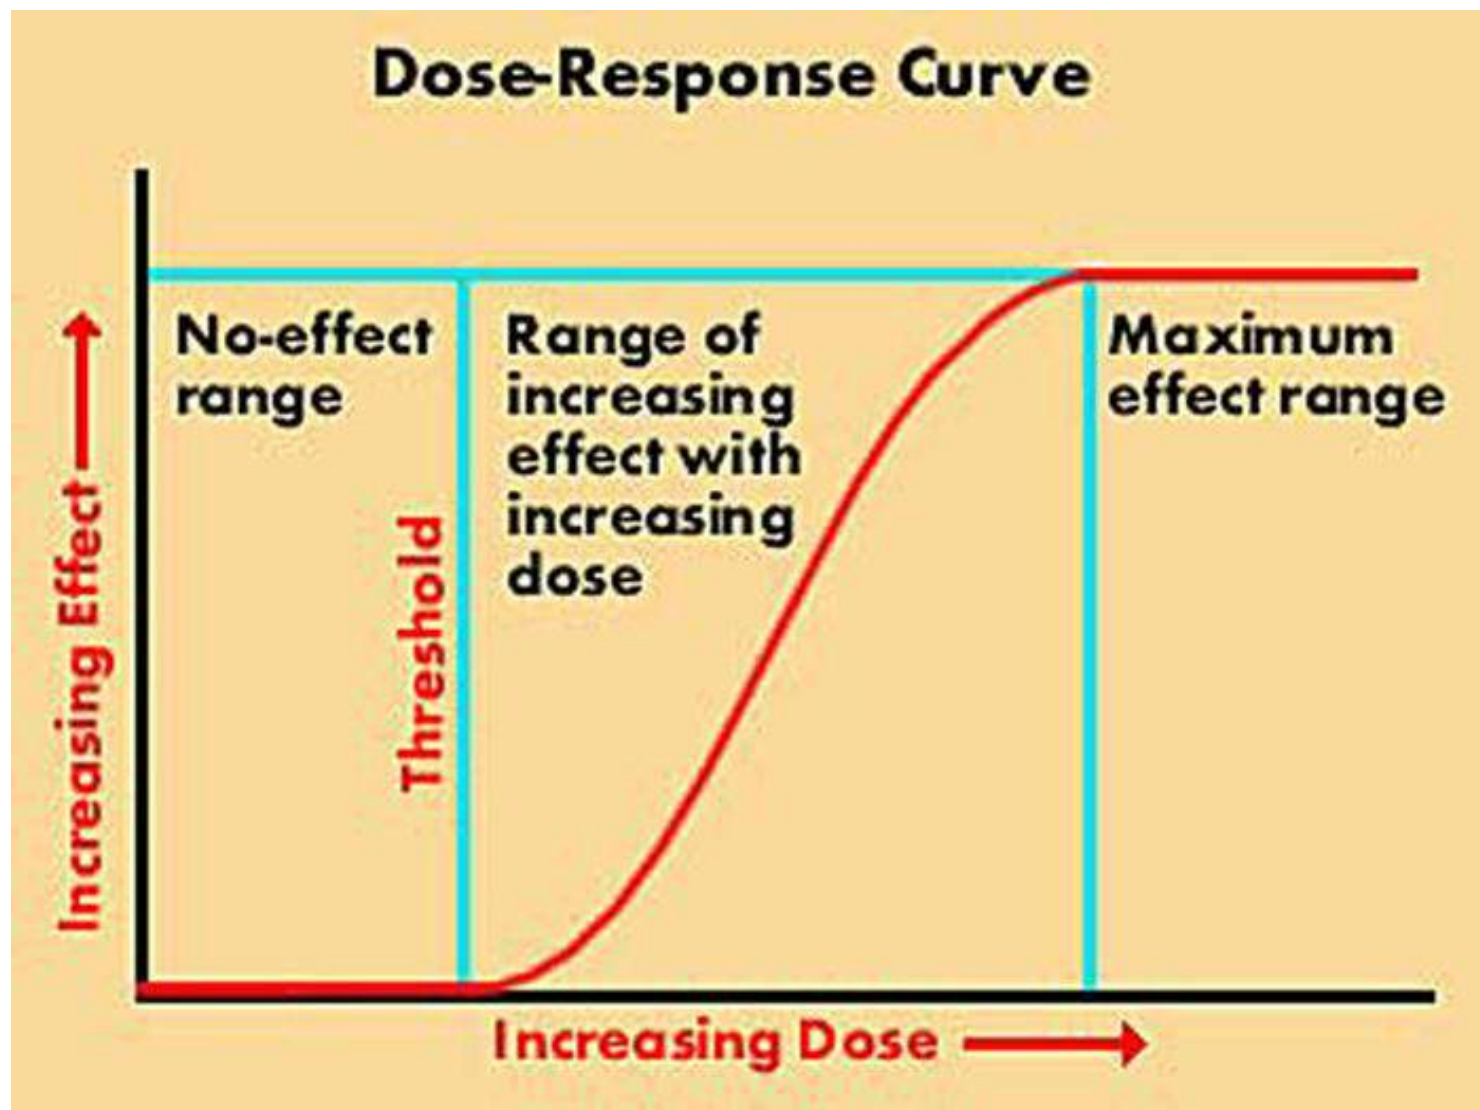

DOSE DETERMINES THE BIOLOGICAL RESPONSE

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose-response relationships

Dose-response relationships

If Mortality is the response, the dose that is lethal to 50% of the population LD₅₀ can be generated from the curve.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose-response relationships

Some chemicals have both therapeutic and toxic effects: Vitamin A

Dose-response relationships

Similar to LD_{50}

- ED_{50}
 - Effective dosage for 50 percent
- TD_{50}
 - Toxic dosage for 50 percent
- Therapeutic Index
 - Ratio of LD_{50} or TD_{50} to ED_{50}
 LD_{50}/ED_{50} or TD_{50}/ED_{50}

The larger value means the margin of safety between the effective dose and toxic dose is greater.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dose-response relationships

Dose-Response Relationship

"The Dose Makes the Poison"

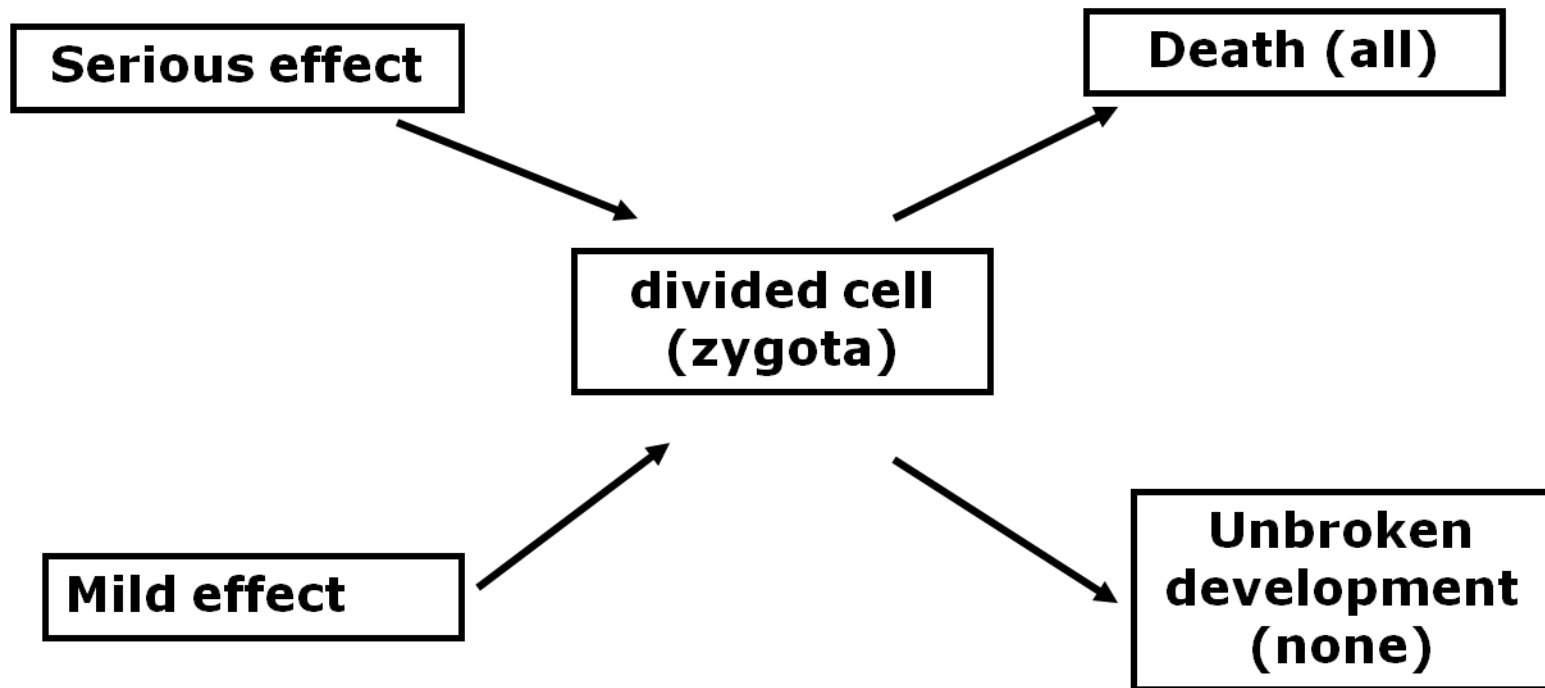

TOXICODYNAMIC PROCESS

- **CLASSIFICATION OF TOXIC EFFECT**
 - ⇒ character of toxic action
 - ⇒ mode of damaging
 - ⇒ site of damaging
 - ⇒ specific toxic effects

CHARACTER OF TOXIC ACTION

All-or-none

CHARACTER OF TOXIC ACTION

Graded – dose-dependent

⇒ NOEL (No Observed Effect Level)

majority of toxic agents

⇒ determine
threshold dose

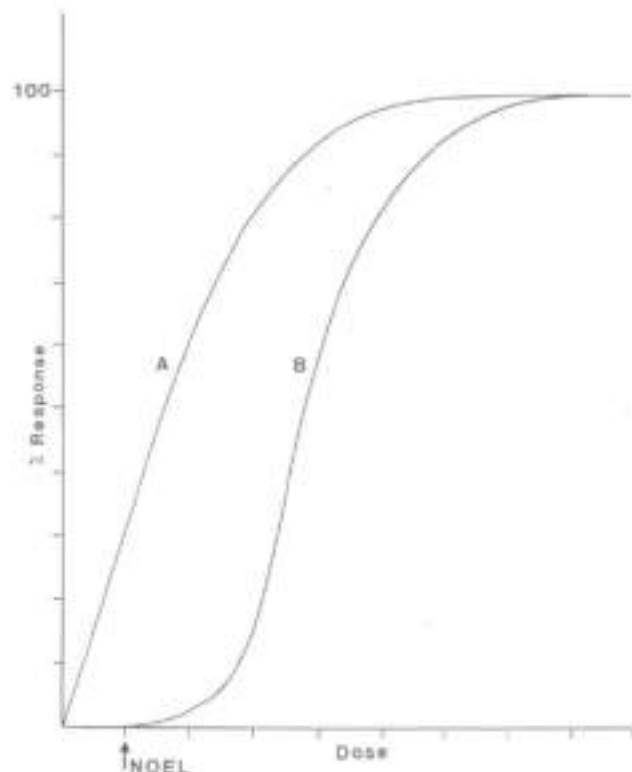

♦ below which

∅ detectable response

♦ above

dose-dependent response

⇒ ∅ threshold dose
(genotoxic carcinogens)

CHARACTER OF TOXIC ACTION

The threshold dose is an important one in toxicology particularly in terms of the **EXTRAPOLATION** of toxic dosis

- ⇒ derived from relatively small scale animal experiments
- ⇒ the subsequent assessment of risk to man

The NOEL is used in setting exposure limits:

➤ ADI – Acceptable Daily Intake (pesticides)

$$\text{ADI} = \frac{\text{NOEL mg/kg}}{\text{SF}}$$

TARGET POINT

General cell poison (acid, alkalis, As, Hg)

Cell and tissue specificity

⇒ **blood poison (CO - Hb)**

⇒ **nerve poison (Cl-CH - neuron)**

MODE OF DAMAGING

Physical interaction with cell constituents

independent from ⇒ fine structure of chemicals
 ⇒ species
generally reversible

⇒ direct action

acids, alkalis – skin, mucous membrane

⇒ change of character

organic solvent – lipid phase of membrane

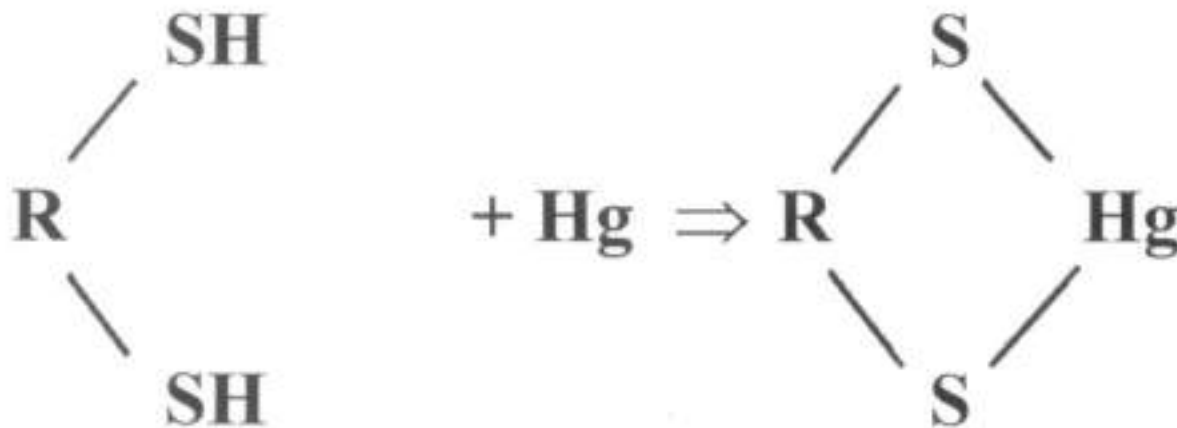

⇒ replacement of oxygen

gases – suffocation

MODE OF DAMAGING

Chemical

chemical substance + component of body = specific reaction
(heavy metals – SH-group, $\text{Se} \Rightarrow \text{S}$)

MODE OF DAMAGING

Biochemical

chemical substance + enzyme

depends on ⇒ fine structure of the chemicals
 ⇒ species

Physiologic

change of physiologic function of living organism
(nerve conduction velocity, body temperature, blood pressure)

SITE OF DAMAGING

CELL MEMBRANE

CELL METABOLISM

CELL NUCLEUS

DAMAGING OF CELL MEMBRANE

- NON-SPECIFIC
- SPECIFIC

NON SPECIFIC

- ⇒ cell death
 - detergents, alcohol
- ⇒ peroxidation of membrane lipids/proteins
 - paraquat, carbon tetrachloride, Cu

DAMAGING OF CELL MEMBRANE

SPECIFIC \Rightarrow selective damaging

\Rightarrow ION CHANNEL

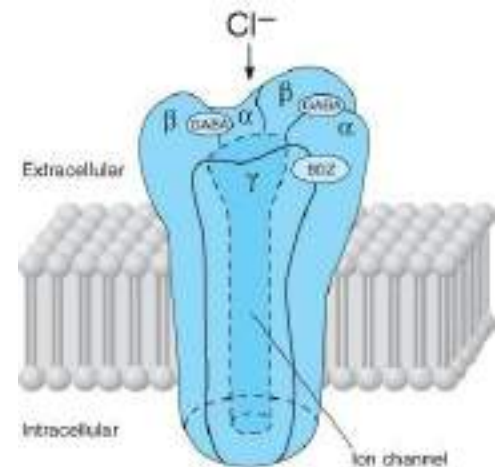

binding \rightarrow changing the membrane potential

\Rightarrow amino acid-receptor (GABA, glycine, glutamate)

change Cl-ion permeability

GABA-antagonist (Cl-CH)

inhibit the release of Cl \Rightarrow convulsion

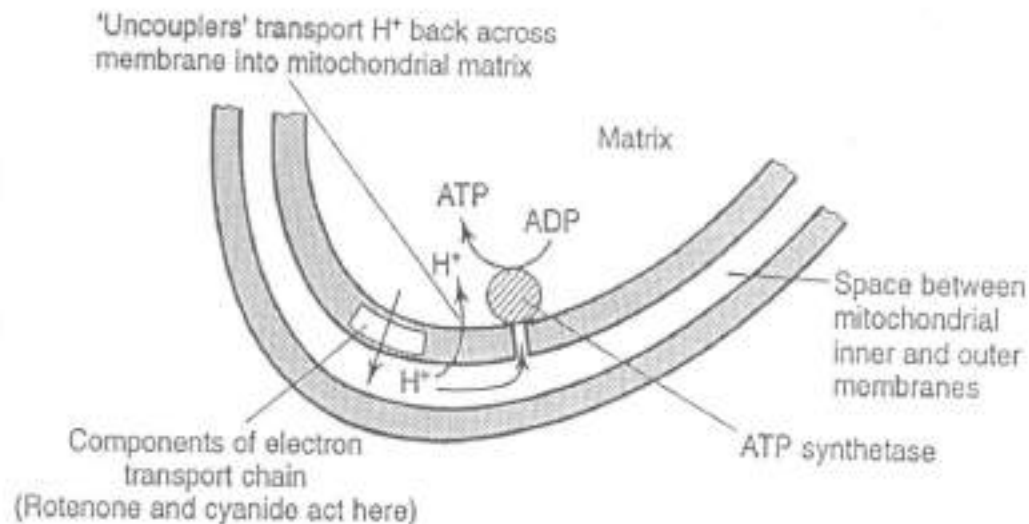

DAMAGING OF CELL METABOLISM

ELECTRON TRANSPORT (mitochondrion)

1⇒ inhibition of cellular respiration

inhibit ETC (NAD-NADH system +
blocking cytochrom oxidase
⇒ cytotoxic anoxia (cyanide)

DAMAGING OF CELL METABOLISM

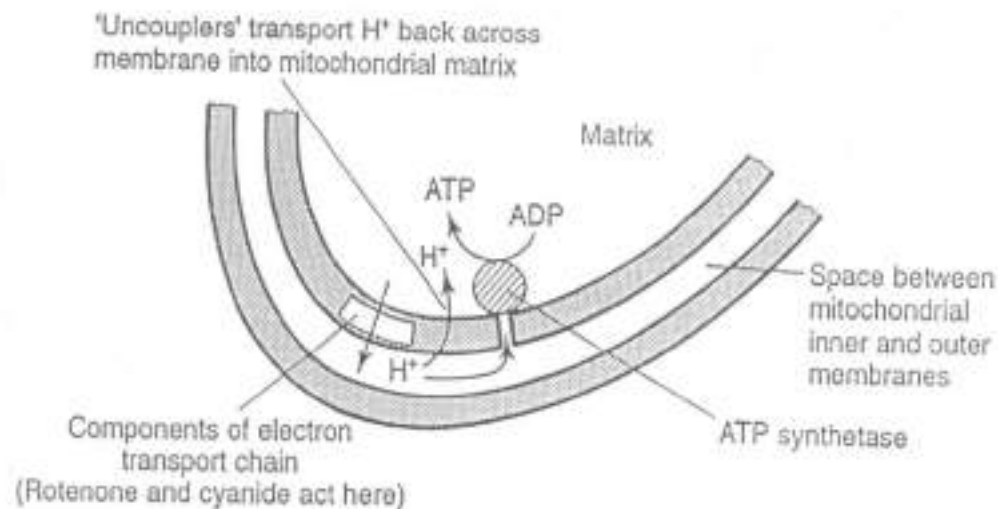

ELECTRON TRANSPORT (mitochondrion)

2⇒ uncoupling of oxidative phosphorylation

uncouple ATP production without blocking ETC

⇒ free energy \emptyset storage

⇒ body temperature \uparrow (dinitro/chloro-fenol)

DAMAGING OF CELL METABOLISM

INHIBITION OF NUCLEIC ACID/PROTEIN SYNTHESIS

- ⇒ alteration in replication/transcription
- ⇒ normal structural/enzyme proteins depleted
(aflatoxin, organomercurials)

INTERFERE WITH FAT MOBILIZATION

- ⇒ accumulation of it in the cell

DAMAGING OF CELL NUCLEUS

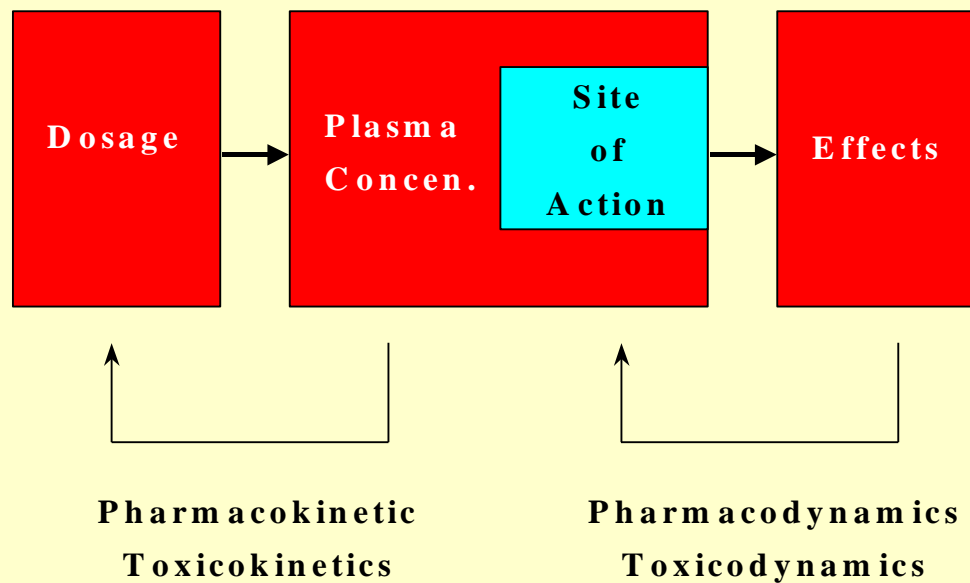

DAMAGE OF DNA

- ⇒ mutation ⇒ mutagenic effect
- ⇒ tumour formation ⇒ carcinogenic effect

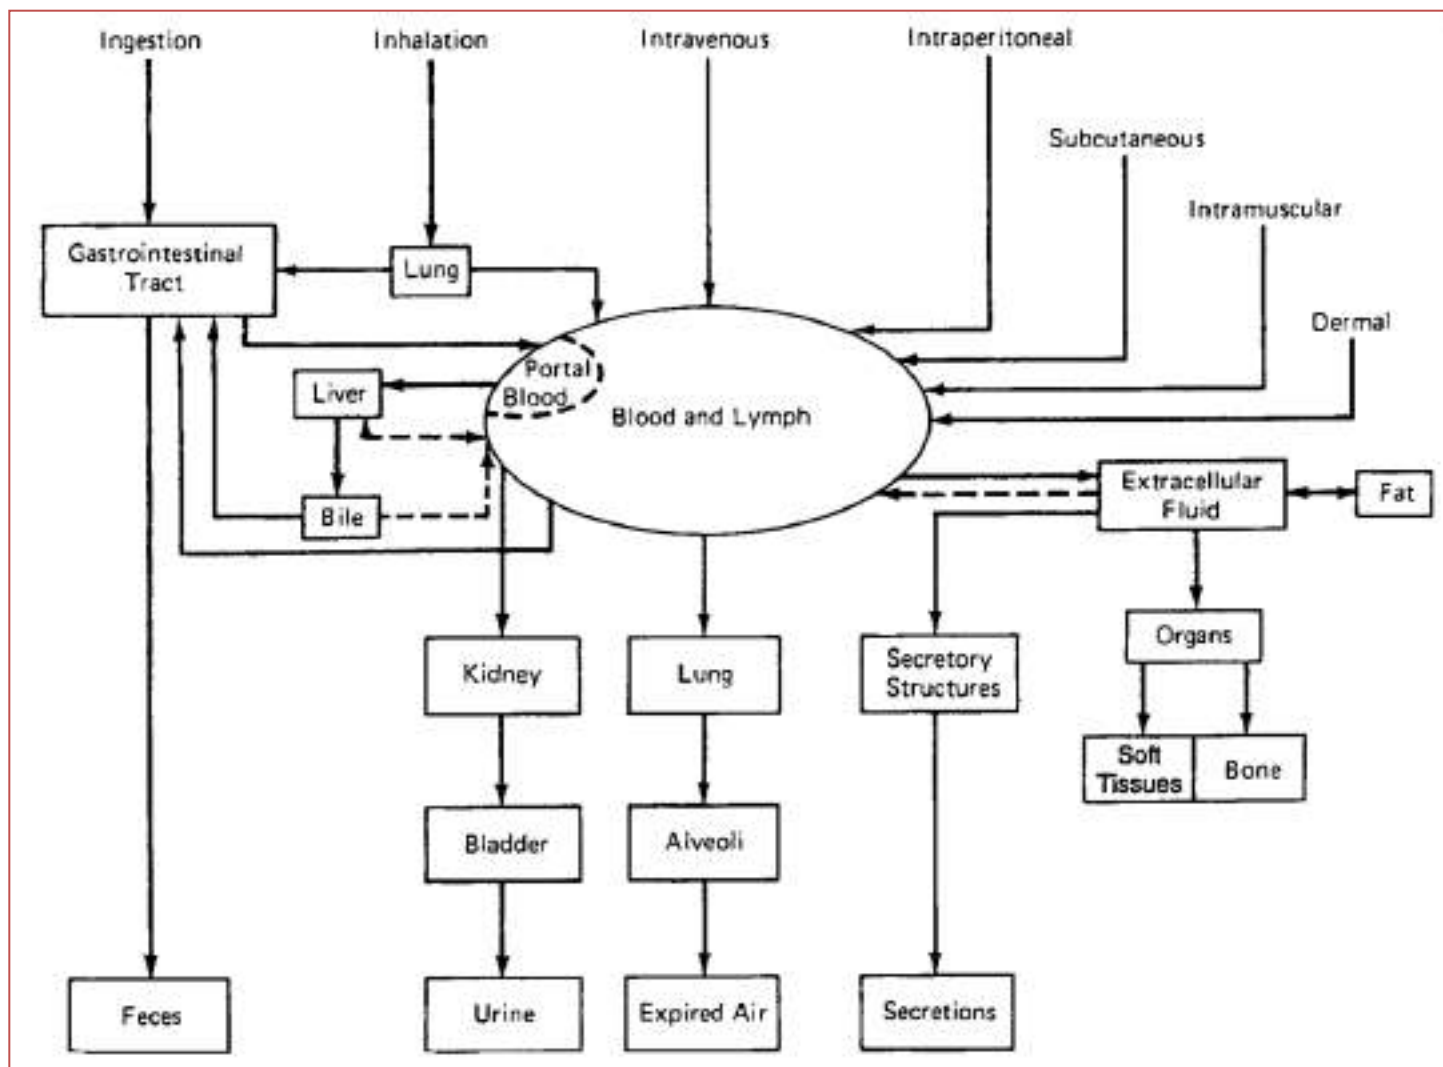

GENOTOXIC CHEMICAL SUBSTANCES

alkylating agents (ethylene imine, β -propiolactone)
nitrosamines, PAH

Toxicokinetics

Toxicokinetics

Chemical substances need to achieve an adequate concentration in their target tissues. If the concentration of the toxic chemical remains low in the target organ of toxicity, little or no toxicity will result, whereas if high concentrations are attained, toxicity will result.

The two fundamental processes that determine the concentration of a chemical substance at any moment and in any region of the body are:

- translocation of chemical molecules,
- biotransformation by metabolism of chemical substance and other processes involved in elimination of chemical substance.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Absorption is the process of entry of chemical substance from site of exposure into systemic circulation.

It is the first step in the toxicokinetics of a chemical substance. If the fraction of the chemical substance absorbed is low or the rate of absorption is low, then only a low concentration of the chemical in the target organ may be obtained and thus no toxicity.

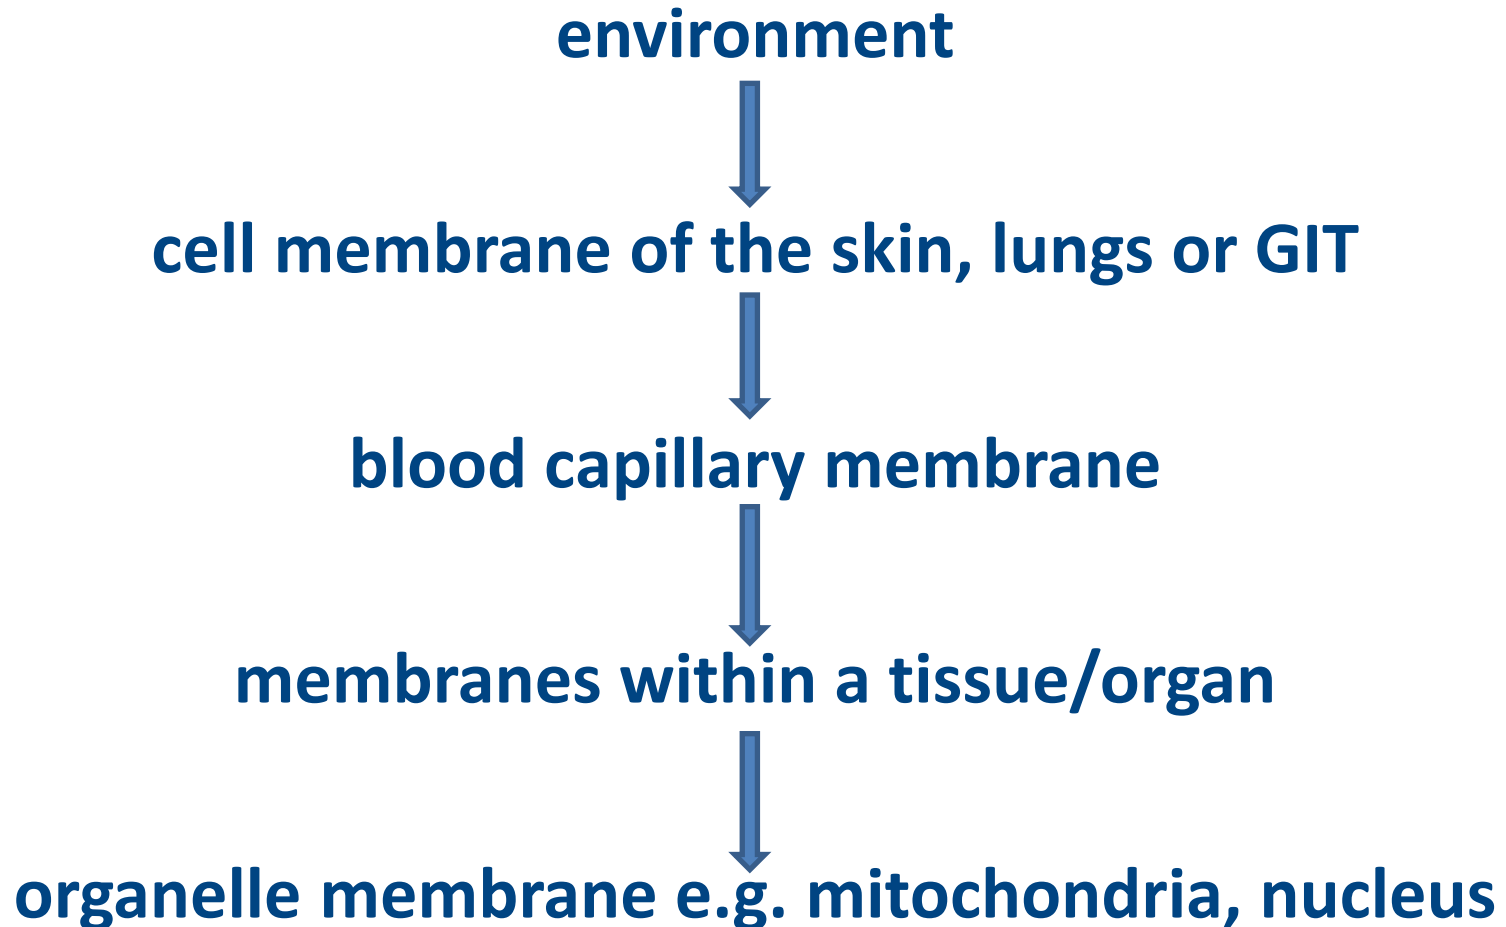

The skin, lung, GIT are the main barriers that separate humans or animals from toxic substances.

Chemical substances must cross one of these barriers to exert adverse effect on the body and then pass through various cell membrane.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Transport across membrane

Structure of membrane

phospholipids + proteins

Transport across membrane

Main properties of membranes

- Sensitivity to peroxidation
 - ⇒ free radicals can damage the membranes
- Selective permeability (semi-permeability)
 - ⇒ certain compounds ⇒ pass through

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Type of transportation

- ⇒ filtration
- ⇒ passive diffusion
- ⇒ active transport
- ⇒ facilitated diffusion
- ⇒ fagocytosis/pinocytosis

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Transport across membrane

Filtration

A difference in concentration of molecules in physical space is called a concentration gradient.

Transport across membrane

Passive diffusion

- ⇒ the most important transport
- ⇒ down a concentration gradient
- ⇒ influencing factors
 - thickness of membrane, surface size
 - concentration of toxic compound
 - lipid solubility
 - distribution coefficient, degree of ionization
- ⇒ rate of diffusion = $K \cdot A (C_2 - C_1)/d$

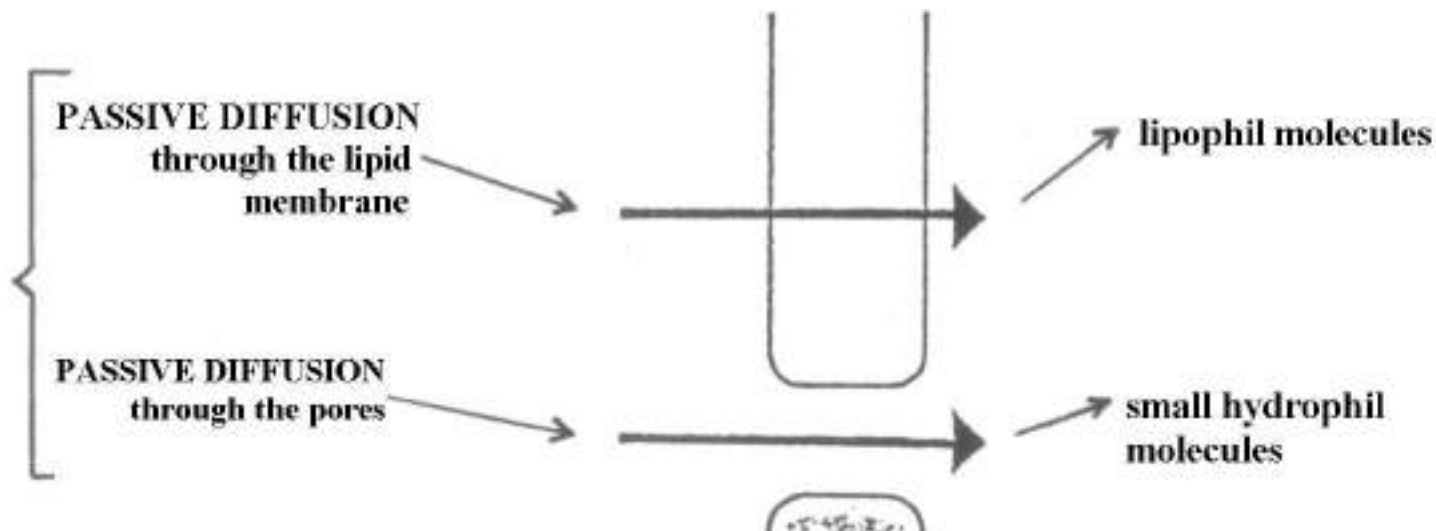

Transport across membrane

Passive diffusion

⇒ conditions

lipid soluble + non-ionized

⇒ energy source: concentration gradient

Transport across membrane

Active transport

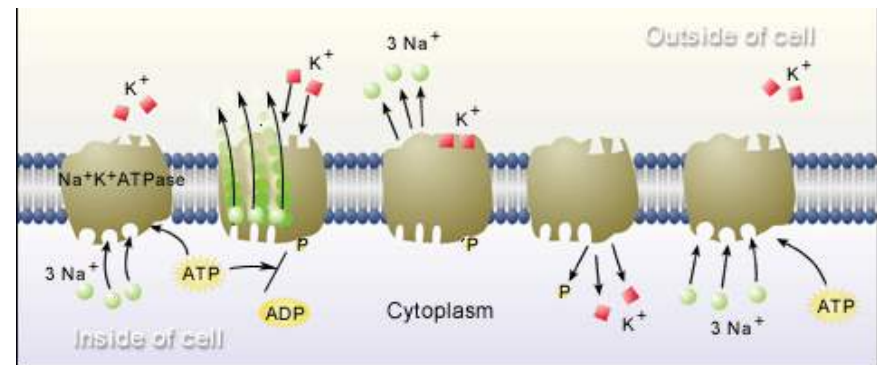

⇒ Energy demanding

- ♦ molecules move against the concentration gradient
- ♦ specific membrane carrier is required
- ♦ metabolic energy (ATP) is necessary
- ♦ may be inhibited by metabolic poison

⇒ nutrients

endogenous substances

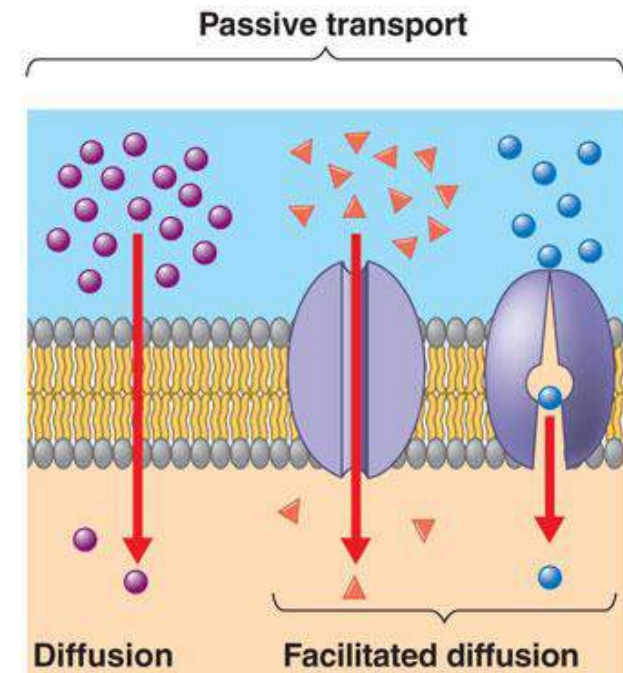

! but xenobiotics also
(lead)

Transport across membrane

Facilitated diffusion

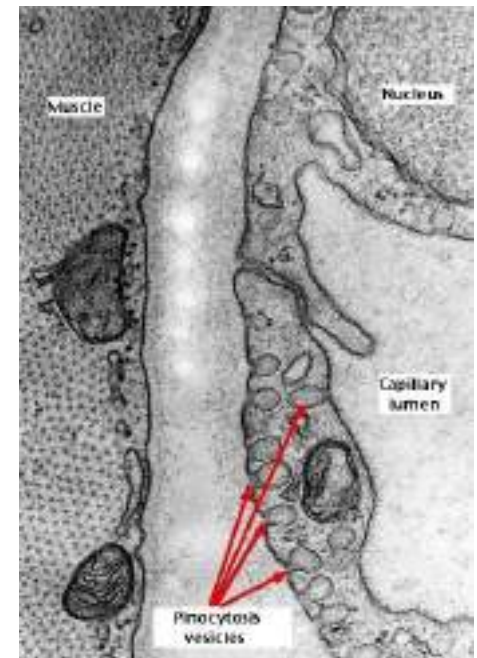

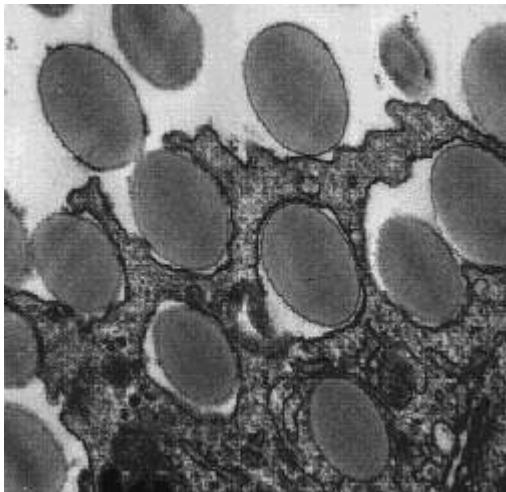

- ⇒ specific membrane carrier is required
- ⇒ metabolic energy \emptyset
- ⇒ energy source: concentration gradient

Transport across membrane

Phagocytosis („cell eating”)/Pinocytosis („cell drinking”)

- ⇒ phagocytosis results in the ingestion of particulate matter from the extracellular fluid
- ⇒ macromolecules/insoluble particles (asbestos)
- ⇒ invagination
- ⇒ energy source: metabolic energy

Specific membrane

⇒ **blood-brain-barrier (BBB)**

- the capillary endothelial cells of the CNS are tightly joined
- the capillaries of the CNS are largely surrounded by glial cells
- the protein concentration in the interstitial fluid of the CNS is much less than elsewhere in the body

⇒ **placental barrier**

⇒ **secretion epithelium (udder)**

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

The rate of transfer of chemical substances across cell membrane is dependent on their physico-chemical properties:

- ⇒ molecular size
- ⇒ lipid solubility (ethanol/water partition coefficient)
- ⇒ ionization
- ⇒ polarity/charge
- ⇒ similarity to endogenous substances

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Ionization

Many chemical substances exist in solution in both the ionized and nonionized form. The ionized form is often unable to penetrate the cell membrane because of its low lipid solubility.

The amount of a weak organic acid and base in the ionized form is dependent on its dissociation constant. The dissociation constant can be expressed as a pK_a → the pH at which an acid or base is 50% dissociated (nonionized=ionized).

The degree of dissociation and ionization of a weak acid or base is dependent on the pH of the medium. When the pH of a solution is equal to the pK_a of a compound, half the chemical exist in the ionized and half in the nonionized state.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Ionization

The degree of ionization of a chemical substance depends both on its pKa and on the pH of the solution in which it is dissolved, a relation described by the Henderson-Hasselbalch equations:

For acids
$$\text{pKa} - \text{pH} = \log \frac{[\text{nonionized}]}{[\text{ionized}]}$$

For bases
$$\text{pKa} - \text{pH} = \log \frac{[\text{ionized}]}{[\text{nonionized}]}$$

pH	Benzoic Acid	% Nonionized	Aniline	% Nonionized
1	<chem>OC(=O)c1ccccc1</chem>	99.9	<chem>[NH3+]c1ccccc1</chem>	0.1
2	<chem>OC(=O)c1ccccc1</chem>	99	<chem>[NH3+]c1ccccc1</chem>	1
3	<chem>OC(=O)c1ccccc1</chem>	90	<chem>[NH3+]c1ccccc1</chem>	10
4	<chem>OC(=O)c1ccccc1</chem>	50	<chem>[NH3+]c1ccccc1</chem>	50
5	<chem>[O-]C(=O)c1ccccc1</chem>	10	<chem>Nc1ccccc1</chem>	90
6	<chem>[O-]C(=O)c1ccccc1</chem>	1	<chem>Nc1ccccc1</chem>	99
7	<chem>[O-]C(=O)c1ccccc1</chem>	0.1	<chem>Nc1ccccc1</chem>	99.9

Figure 3-3. Effect of pH on the ionization of benzoic acid (pKa = 4) and aniline (pKa = 5).

As the pH decreases, more of the acid becomes nonionized → diffuse across membranes.

As the pH increases, more of the base becomes nonionized → diffuse across membranes.

PROCESSES OF TOXIKOKINETICS

- ⇒ ABSORPTION
- ⇒ DISTRIBUTION
- ⇒ METABOLISM
- ⇒ EXCRETION

TÁMOP-4.1.2.A/2-10/1-2010-0012

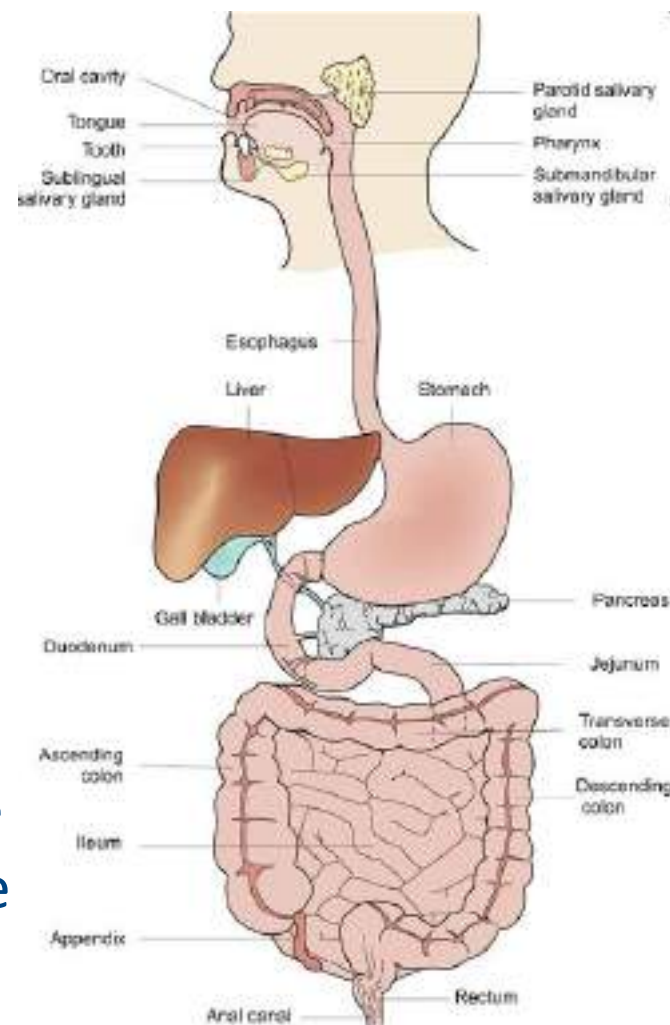

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ABSORPTION GASTROINTESTINAL TRACT

The GIT is one of the most important routes by which chemical substances are absorbed. Most chemical substances that are ingested by the oral route do not produce a systemic effect unless they are absorbed.

Absorption can occur at any point along the GIT.

Lipid soluble, non-ionized compounds can be absorbed along the whole length \Rightarrow passive diffusion.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ABSORPTION GASTROINTESTINAL TRACT

If a chemical substance is a weak organic acid or base, it will tend to be absorbed by diffusion in that part of the GIT in which it exist in the most lipid-soluble (nonionized) form.

Since gastric juice is acidic, and the intestinal contents are nearly neutral → the lipid solubility can differ markedly.

Weak organic acid → nonionized in the stomach → absorbed in the stomach

Weak organic acid → ionized in the intestine → hardly absorbed in the intestine

FOR WEAK ACIDS	
$pK_a - pH = \log \frac{[\text{nonionized}]}{[\text{ionized}]}$	
Benzoic acid $pK_a \approx 4$	
Stomach $pH \approx 2$	
$4 - 2 = \log \frac{[\text{nonionized}]}{[\text{ionized}]}$	
$2 = \log \frac{[\text{nonionized}]}{[\text{ionized}]}$	
$10^2 = \frac{[\text{nonionized}]}{[\text{ionized}]}$	
$100 = \frac{[\text{nonionized}]}{[\text{ionized}]}$	
Ratio favors absorption	
Intestine $pH \approx 6$	
$4 - 6 = \log \frac{[\text{nonionized}]}{[\text{ionized}]}$	
$-2 = \log \frac{[\text{nonionized}]}{[\text{ionized}]}$	
$10^{-2} = \frac{[\text{nonionized}]}{[\text{ionized}]}$	
$\frac{1}{100} = \frac{[\text{nonionized}]}{[\text{ionized}]}$	
Ratio favors absorption	
FOR WEAK BASES	
$pK_b - pH = \log \frac{[\text{ionized}]}{[\text{nonionized}]}$	
Aniline $pK_b \approx 5$	
Stomach $pH \approx 2$	
$5 - 2 = \log \frac{[\text{ionized}]}{[\text{nonionized}]}$	
$3 = \log \frac{[\text{ionized}]}{[\text{nonionized}]}$	
$10^3 = \frac{[\text{ionized}]}{[\text{nonionized}]}$	
$1000 = \frac{[\text{ionized}]}{[\text{nonionized}]}$	
Ratio favors absorption	
Intestine $pH \approx 6$	
$5 - 6 = \log \frac{[\text{ionized}]}{[\text{nonionized}]}$	
$-1 = \log \frac{[\text{ionized}]}{[\text{nonionized}]}$	
$10^{-1} = \frac{[\text{ionized}]}{[\text{nonionized}]}$	
$\frac{1}{10} = \frac{[\text{ionized}]}{[\text{nonionized}]}$	
Ratio favors absorption	

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ABSORPTION GASTROINTESTINAL TRACT

- ⇒ water soluble, small molecules ⇒ filtration
- ⇒ water soluble, macromolecules ⇒ carrier-mediated

INFLUENCING FACTORS

- ⇒ the chemical substance may be altered by the acid, enzymes, or intestinal flora to form a new compound that may differ in toxicity from the parent compound (e.g. snake venom)
 - ⇒ alteration of GIT motility can affect the absorption of chemical substances (decreased motility → increase the overall absorption)
 - ⇒ food (one metal can alter the absorption of another)
e.g. $\text{Cd} \rightarrow \text{Zn}$, Cu ; $\text{Zn} \rightarrow \text{Cu}$, $\text{Mg} \rightarrow \text{F}$; milk $\rightarrow \text{Pb}$

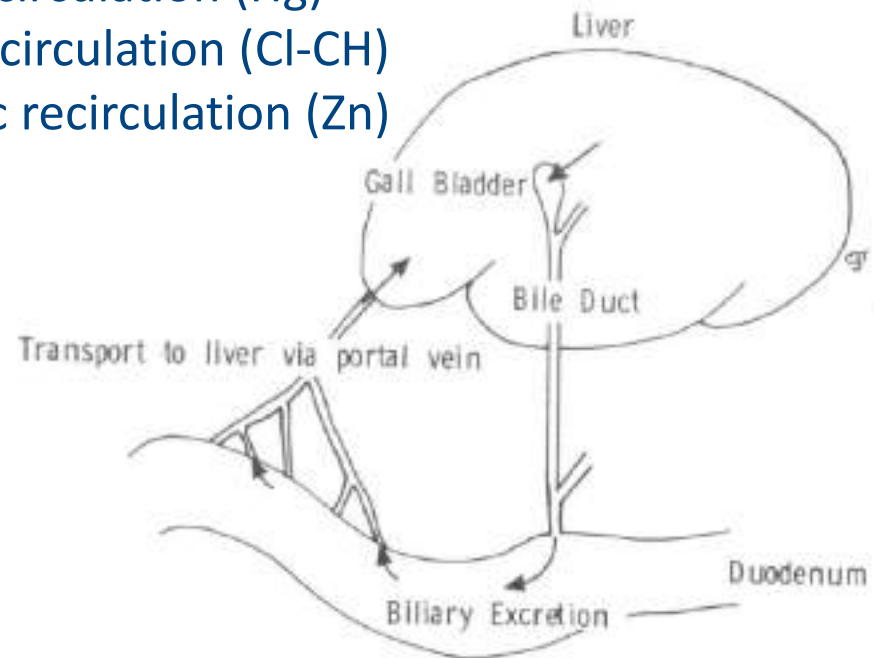

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ABSORPTION GASTROINTESTINAL TRACT

EXCRETION + RE-ABSORPTION ⇔ RECIRCULATION

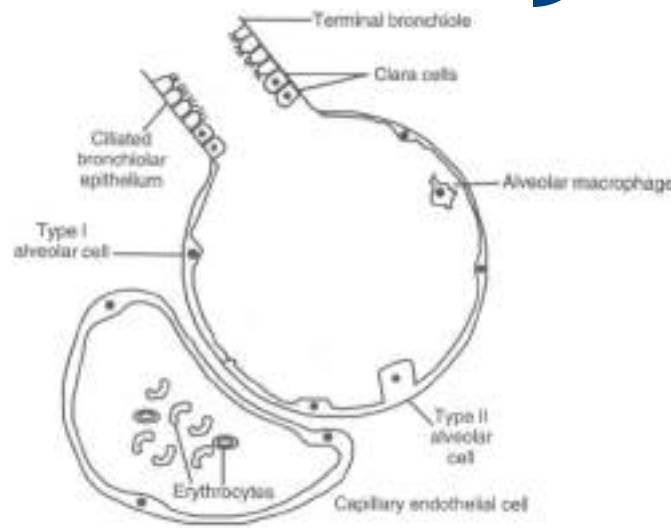

- ⇒ gastro-salivaris recirculation (Hg)
- ⇒ entero-hepatic recirculation (Cl-CH)
- ⇒ entero-pancreatic recirculation (Zn)

ABSORPTION LUNG - AIRWAYS

- ⇒ large surface area (50-100 m²)
- ⇒ excellent blood supply
- ⇒ thin barrier

} rapid absorption

ABSORPTION

LUNG - AIRWAYS

⇒ gases, vapours, volatile liquids, aerosols

the rate of absorption of gases is variable and dependent on the chemical substance's blood:gas solubility

liquid aerosol, if lipid-soluble, will readily cross the alveolar cell membranes by passive diffusion

⇒ solid particles (smoke, powder)

depends on size

$< 1 \mu\text{m}$ ⇒ absorb into blood

$> 1 \mu\text{m}$ ⇒ phagocytosis

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

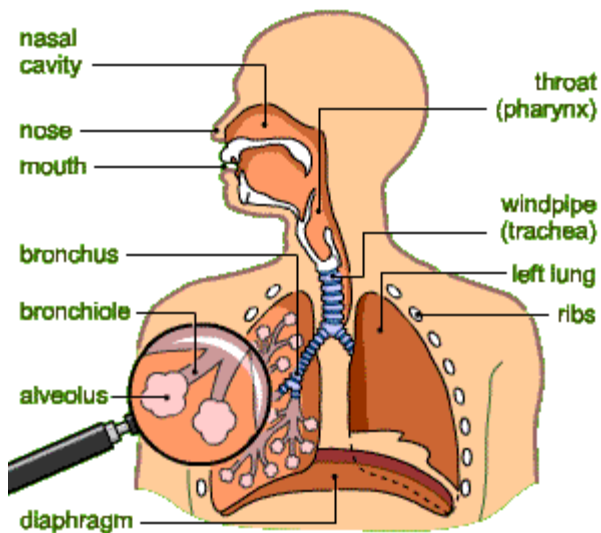

Image src: <http://www.bbc.co.uk/schools/gcsebitesize/img/pe01021.gif>

Nasopharyngeal Region

5-30 μm

Trachea

Bronchi

Bronchioles

1-5 μm

The alveolar region is an area of the lung where chemical substances readily absorbed

Alveolar Region

1 μm

ABSORPTION SKIN

The skin is a relatively good lipoid barrier separating humans or animals from their environment.

Some chemical substances can be absorbed through the skin in sufficient quantities to produce systemic effect.
(e.g. nerve gases → Sarin).

In order to be absorbed through the skin, a chemical substance must cross several cell layers to reach blood vessels.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ABSORPTION SKIN

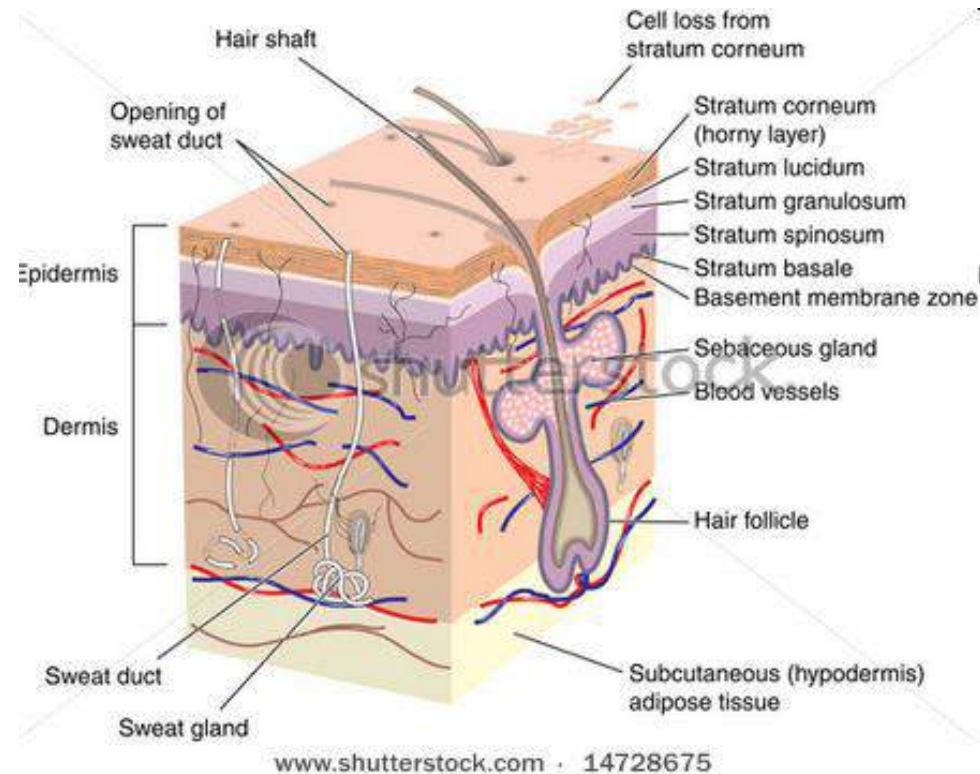

Phases of skin absorption:

⇒ through the epidermis (rate-limiting barrier)

stratum corneum (thin, keratin-filled, dried cell layer → dead surface layer)

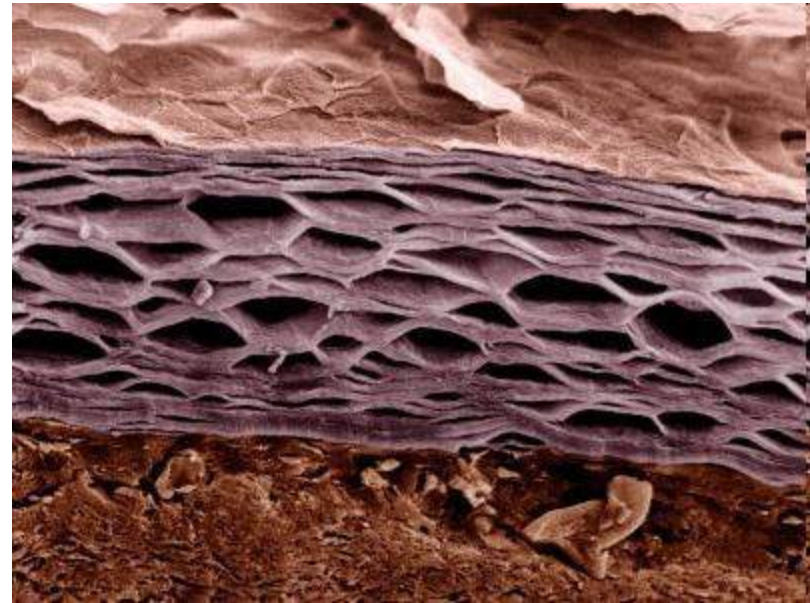

⇒ mainly lipid soluble substances can cross

⇒ through the dermis (porous, watery diffusion medium)

ABSORPTION SKIN

- The stratum corneum plays a critical role in determining cutaneous permeability.
 - ⇒ intact
absorption limited
 - ⇒ injured
increase permeability
- Hydration of skin
 - ⇒ the water increases the permeability of the stratum corneum
- Site (thick on the palm and sole 400-600 μm
thin on the arms, back, legs, abdomen 8-15 μm)

DISTRIBUTION

Movement of chemical substance from the systemic circulation (blood) to peripheral compartments (tissues) where the chemical substance is present.

Distribution of a chemical substance from systemic circulation to tissues is dependent on the ability of the chemical substance to pass through the cell membrane of the various tissue (lipid solubility, ionization, molecular size), binding to plasma proteins, rate of blood flow and special barriers.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

DISTRIBUTION

BLOOD - BINDING

Chemical substances are present in blood in:

Free form: active, diffusible, available for biotransformation and excretion.

Bound form: inert, non-diffusible, not available for metabolism, excretion and entering the target organ to produce injury.

➤ **erythrocyte** (Pb, organic Hg)

⇒ adsorption on surface

⇒ binding to component (Hb – CO)

➤ **plasma proteins**

⇒ albumin (inorganic Hg, aromatic CH
Ca, Zn, Cd, I, Br)

⇒ globulin (small molecule: Cu, Zn, Fe)
+ lipid soluble substance

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

DISTRIBUTION

BLOOD - BINDING

➤ CONSEQUENCES

⇒ cc. of free molecule ↓

⇒ rate of tissue distribution ↓

⇒ rate of excretion ↓

⇒ time of onset ↑

⇒ saturation of binding capacity may occur

⇒ cc. of free molecules ↑

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

TISSUE DISTRIBUTION

⇒ across capillaries, membranes
by transport mechanisms
passive diffusion
specific transport systems (active
transport)
phagocytosis-pinocytosis

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

TISSUE BINDING STORAGE

Selective distribution.

Chemical substances are often concentrated in a specific tissue.

⇒ Pb	⇒ RBC, liver, bone
⇒ F	⇒ bone, tooth
⇒ Cu	⇒ liver
⇒ As	⇒ hair, bone
⇒ Se	⇒ horny matter
⇒ Cl-CH	⇒ fat tissue

CONSEQUENCES

⇒ toxicity ↓ (protectiv mechanism)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

REDISTRIBUTION - ACCUMULATION

The distribution of a chemical substance in the body can change with time.

⇒ Pb ⇒ RBC, liver (immediately after absorption)

⇒ Pb ⇒ bone (90% a month after administration)

⇒ highly lipophilic chemicals ⇒ brain (well-perfused tissue)

⇒ highly lipophilic chemicals ⇒ fat (less well-perfused tissue)

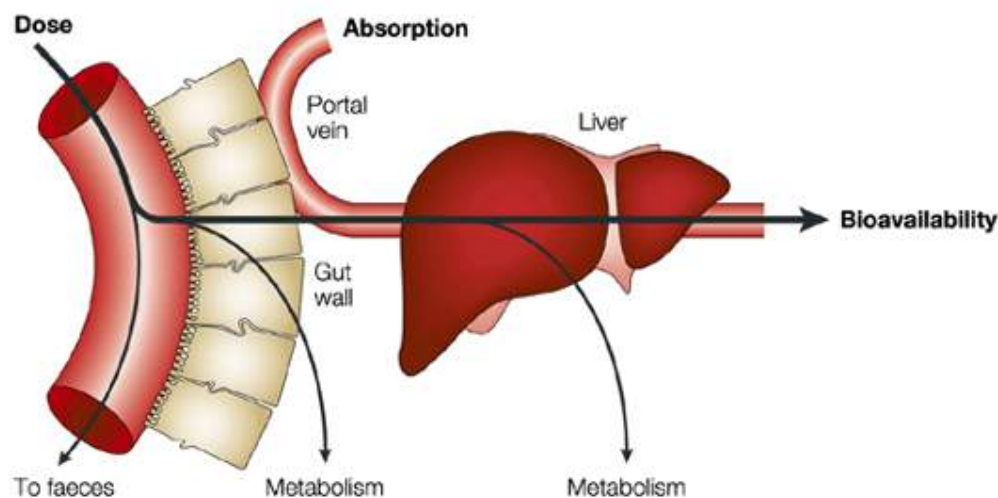

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

FIRST PASS EFFECT

After oral absorption of a chemical substance before entering the general blood circulation, it can be biotransformed by the gastrointestinal cells and the liver.

Nature Reviews | Drug Discovery

Metabolism = biotransformation

The conversion of a chemical substance from one form to another by the actions of organisms or enzymes.

The chemical structure and physicochemical properties of chemical substances are changed by the enzymatic metabolism.

Biotransformations occur between absorption and elimination from kidneys.

In general, enzymatic metabolism: transforms lipophilic parent chemical substances to more hydrophilic metabolites, which can be readily excreted into bile or urine.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Biotransformation can also result in bioactivation, which involves the production of reactive metabolites that are more toxic, mutagenic, or carcinogenic than their parent compound(s).

Chemical substances may be converted to:

- less toxic metabolites
- more toxic metabolites
- metabolites with different type of effect or toxicity

The body metabolises not only exogenous (foreign) substances but endogenous (internally created) substances too.

Metabolism in the body can be divided into two different types of reactions: Phase I reactions and Phase II reactions.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Toxicokinetics

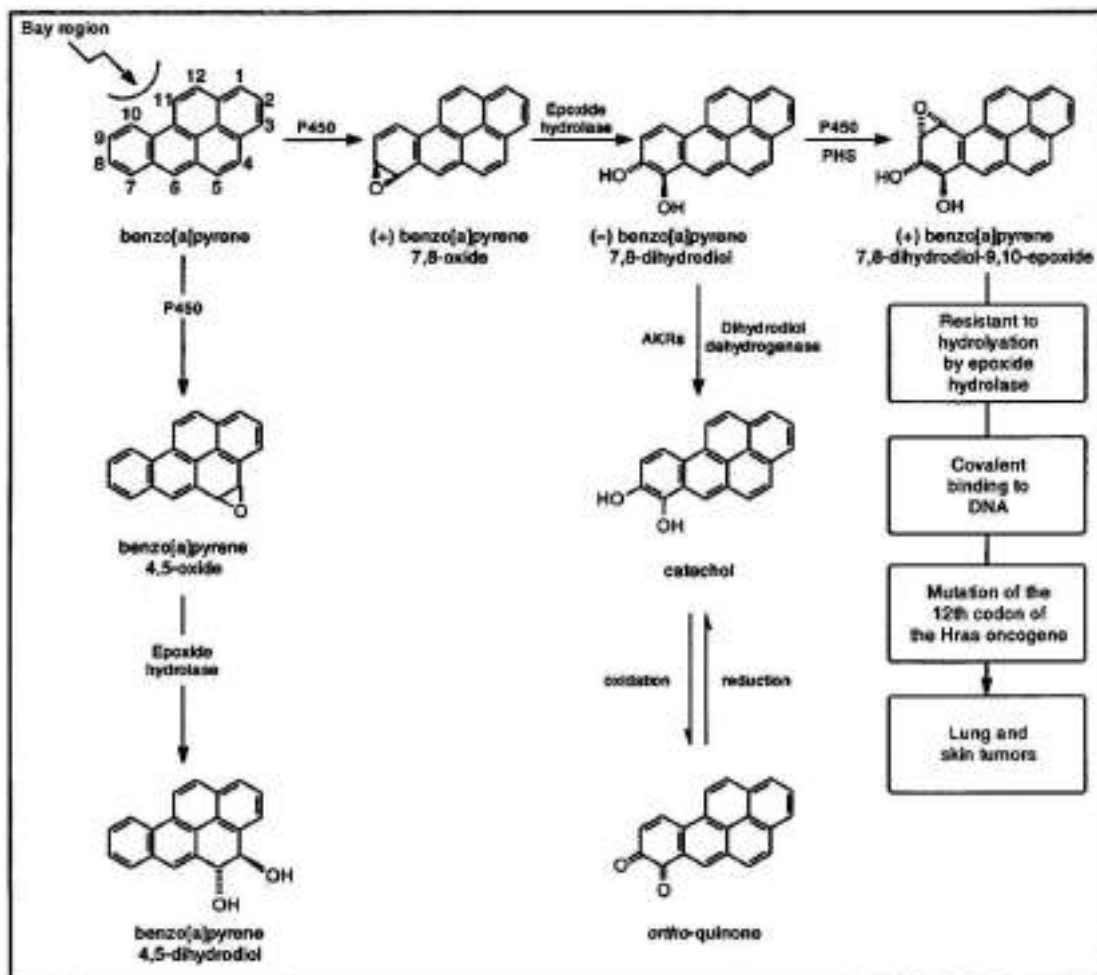

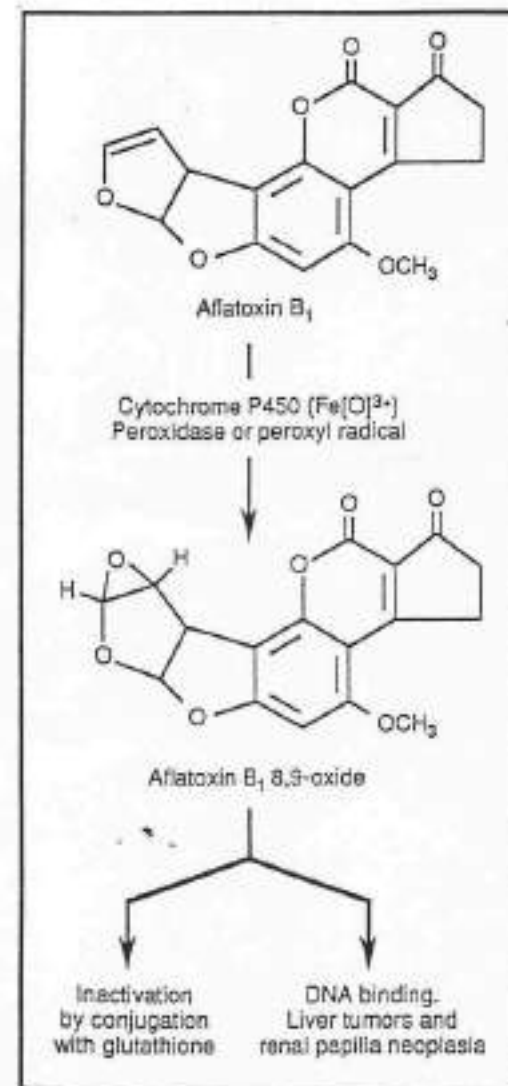

Figure 6-6. Role of epoxide hydrolase in the inactivation of benzo[a]pyrene 4,5-oxide and in the conversion of benzo[a]pyrene to its tumorigenic bay-region diolepoxide.

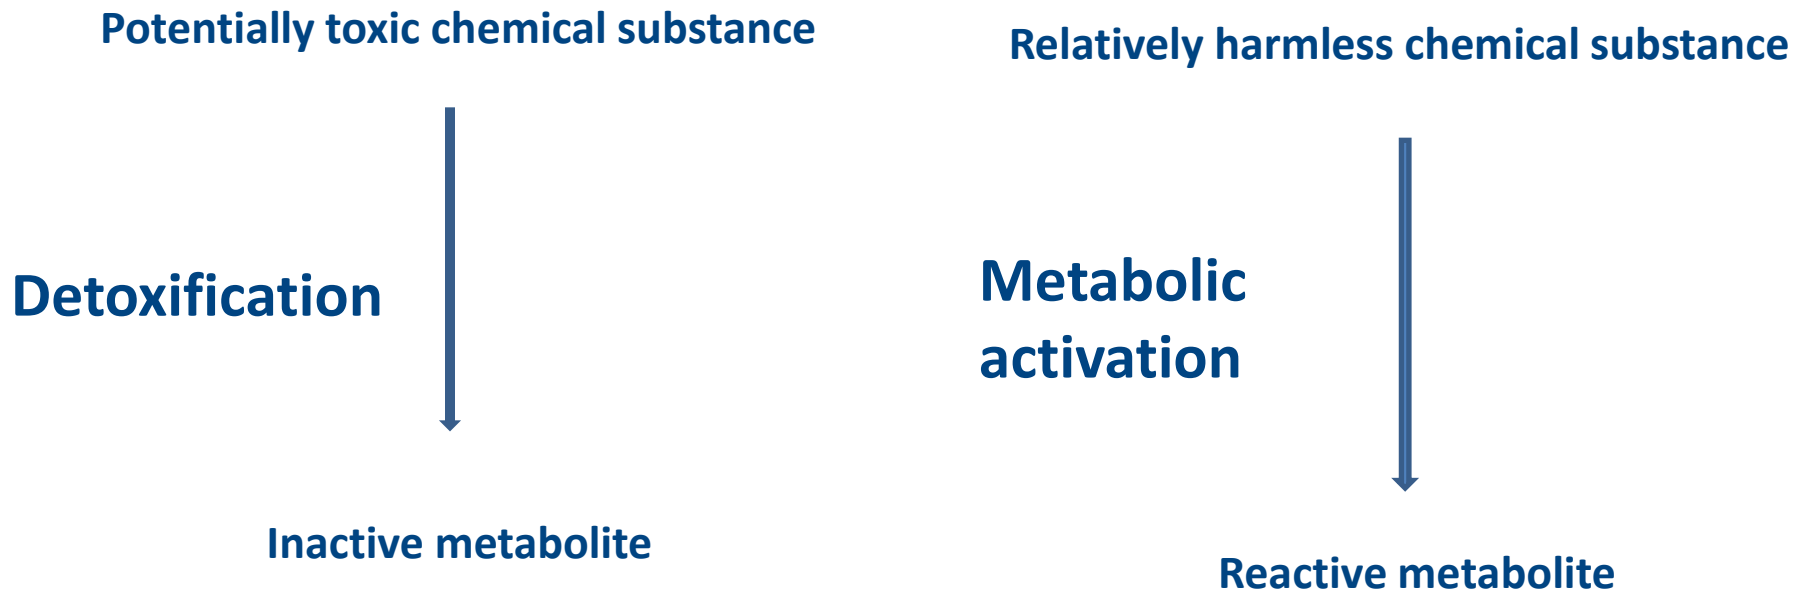

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Befektetés a jövőbe

METABOLISM

Phase I reactions: introduces or uncovers polar functional groups that provide sites for Phase II metabolism.

Major classes of reaction:

- oxidation
- reduction
- hydrolysis

Principal Phase I enzymes:

- Cytochrome P450 enzymes
- Flavin monooxygenases
- Monoamine oxidases
- Esterases
- Amidases
- Hydrolases
- Reductases, dehydrogenases, oxidases

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

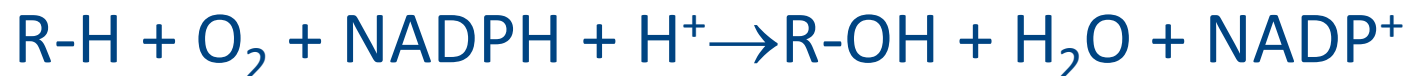

Cytochrome P450 enzymes

The most important metabolizing enzyme for chemical substances.

Reaction type is mainly oxidation in the presence of oxygen or reduction under low oxygen tension.

Located in the smooth endoplasmic reticulum of all major organs and tissues (especially liver, intestine, kidney, skin, brain).

Overall reaction

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Cytochrome P450 enzymes

Substrate specificity is very low.

Attributes

- Genetic Polymorphism
- Enzyme Induction
- Enzyme Inhibition

Multiple CYP gene families have been identified in humans, and the categories are based upon protein sequence homology.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Polymorphic enzymes

Cytochrome P450 Enzymes:

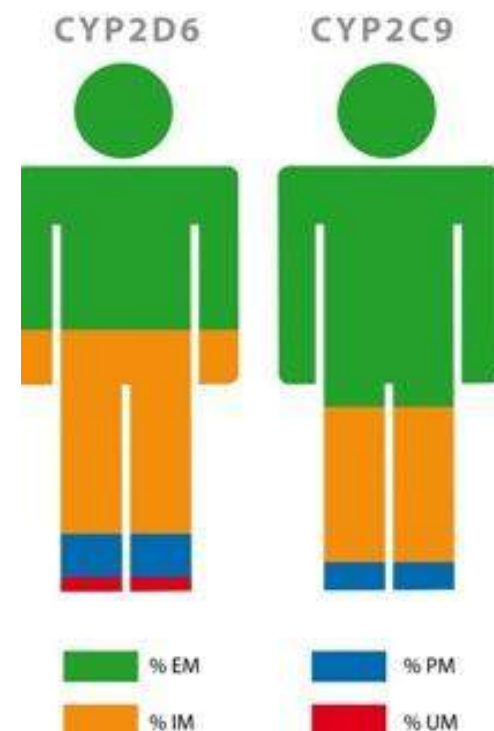

- CYP 2D6
- CYP 2C19
- CYP 2C9

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

- **CYP 2D6 in Caucasians:**
 - PM: 7%
 - IM: 40%
 - EM: 50% (normal metabolizers)
 - UM: 3%
- **CYP 2C19 in Caucasians:**
 - PM: 3%
 - IM: 27%
 - EM: 70% (normal metabolizers)

Kirchheiner J, Nickchen K, Bauer M, et al. Mol Psychiatry 2004 May; 9 (5):442-73.

CYP1A1

- Metabolizes PAHs
- PAH-inducible
- Ubiquitous
- Expressed in utero, even 12-h ovum

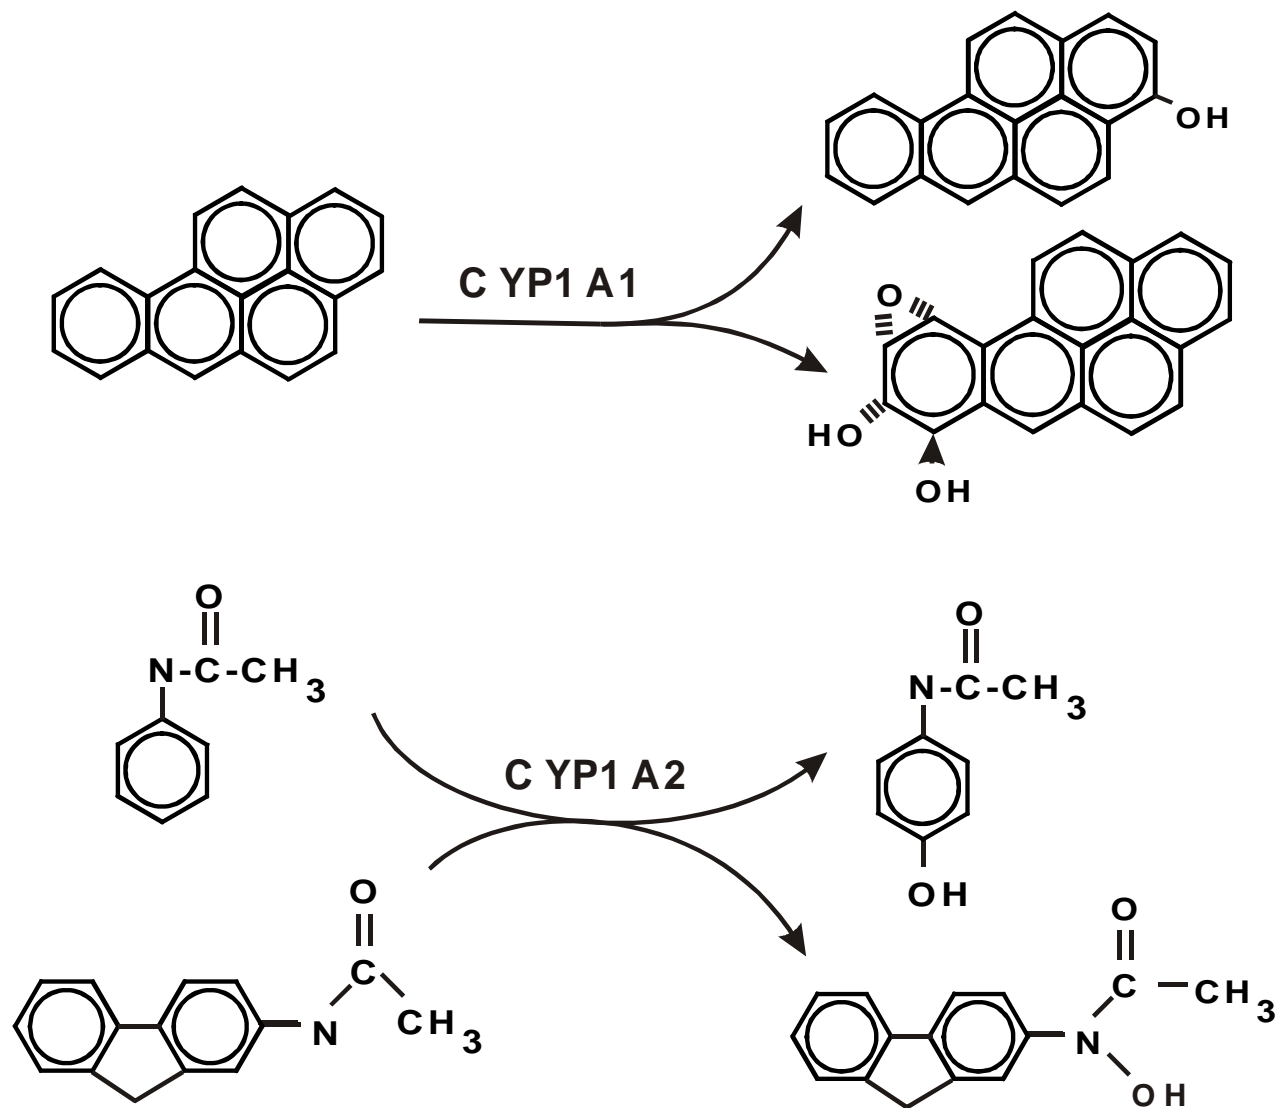

CYP1A2

- Metabolizes aryl and alkyl amines
- PAH-inducible
- Not detectable until neonatal period

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

General rule of big pharma

Any candidate drug that shows inducibility of CYP1A1/1A2/1B1 is regarded as hazardous, potentially **cancer-causing**.

Such candidate drugs — usually **abandoned immediately**, without further cost to the company.

TÁMOP-4.1.2.A/2-10/1-2010-0012

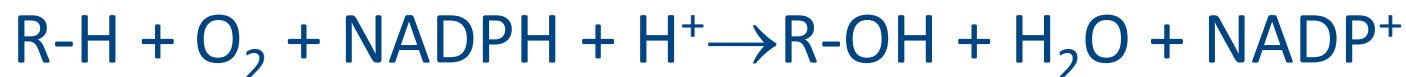

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Flavin monooxygenases

- Flavoprotein
- Mixed-function amine oxidase
- Located in smooth endoplasmic reticulum in human, rabbit liver, guinea-pig lung, human kidney
- Uses NADPH as a source of reducing equivalents
- Not inducible

Overall reaction

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Monoamine oxidases

- Metabolizes endogenous monoamine neurotransmitters
- Found in the endoplasmic reticulum and in mitochondria, of nerve endings and liver
- Uses NADPH as a source of reducing equivalents

Overall reaction

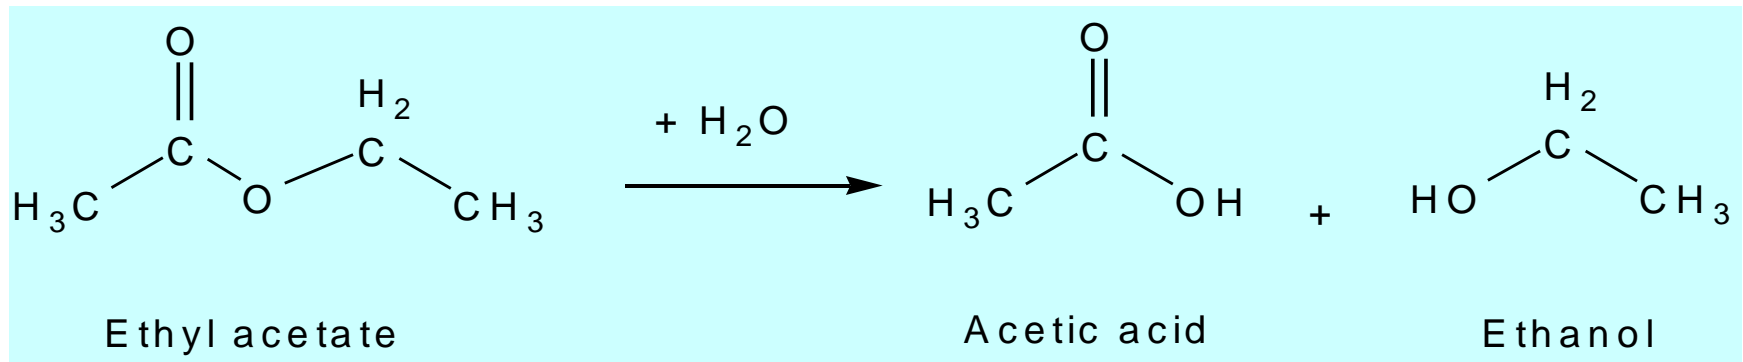

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Esterases

Hydrolyse esters to carboxylic acid and alcohol functional groups.

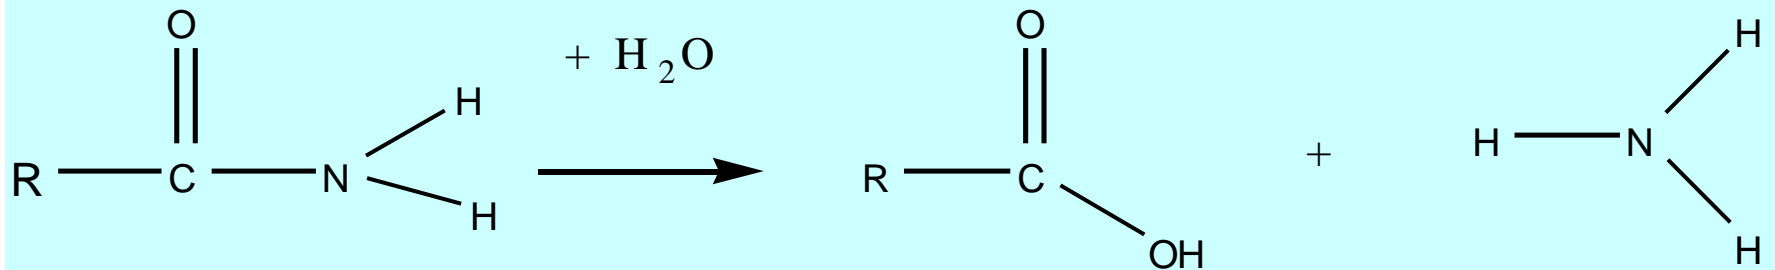

Non-specific esterases in plasma, more substrate-specific forms in liver cytosol.

Amidases

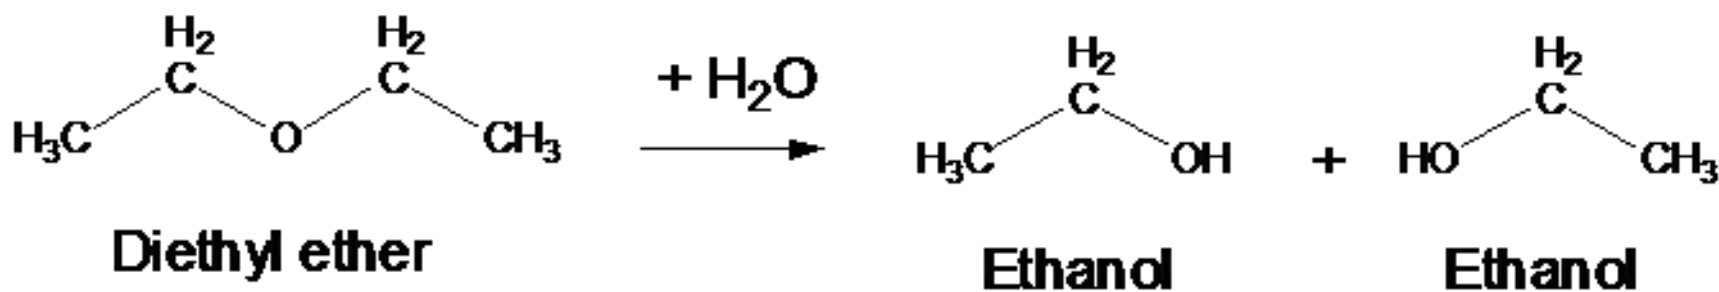

Hydrolyse amides to carboxylic acids and amines (or ammonia).

Found in plasma and in liver cytosol.

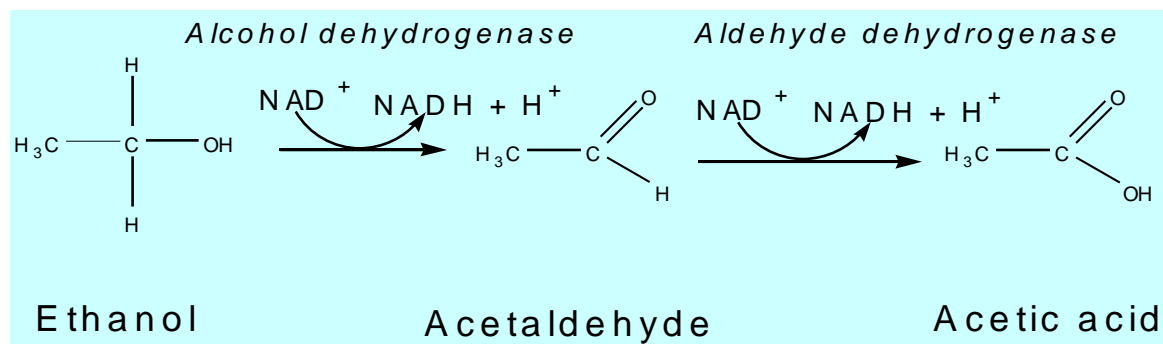

Hydrolases

Hydrolyse ethers.

Reductases, dehydrogenases, oxidases

Found in cytosol, endoplasmic reticulum, mitochondria.

METABOLISM

Phase II reactions

Functional group or metabolite formed by phase I is masked by conjugation with natural endogenous constituent as glucuronic acid, glutathione, sulphate, acetic acid, glycine or methyl group.

These reactions usually result in chemical substance inactivation with few exceptions e.g. morphine-6-conjugate is active.

Phase II reactions usually occur after Phase I but can also take place earlier than Phase I.

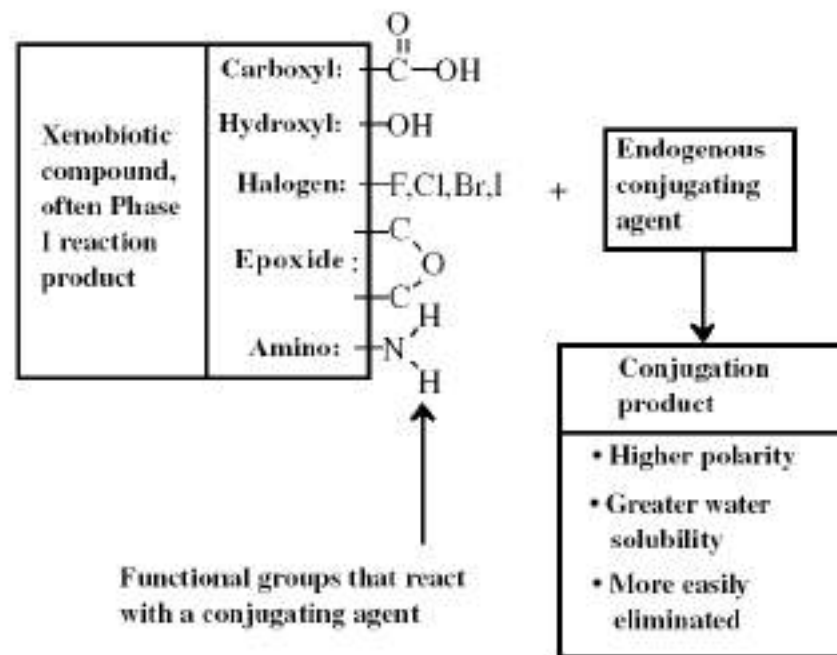

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Phase II Metabolism requires the presence of a reactive group:

- Hydroxyl group (R-OH)
- Amino group (R-NH₂)
- Carboxyl group (R-COOH)
- Epoxide group (R₁-COC-R₂)
- Thiol group (R-SH)
- Halogen group (R-X)
- Electrophiles
- Some others

Toxicokinetics

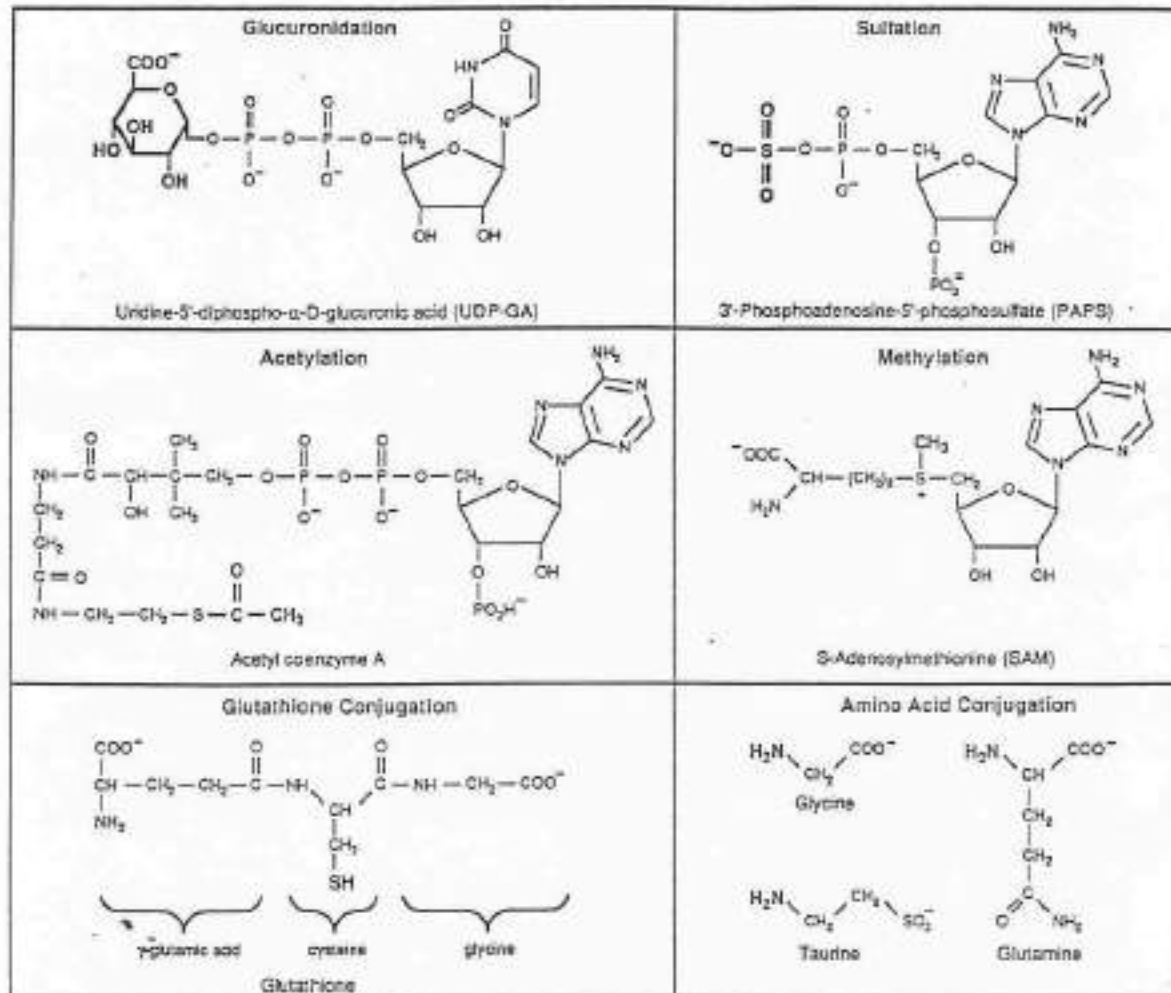

Figure 6-41. Structures of cofactors for phase II biotransformation.

The functional group that reacts with or is transferred to the xenobiotics is shown in bold.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Befektetés a jövőbe

Conjugation by Glucuronides

Most common endogenous conjugating agents in the body react with xenobiotics through the action of uridine diphosphate glucuronic acid (UDPGA - cofactor).

Group transferred glucuronic acid.

Transfer is mediated by UDP glucuronosyl transferase enzymes.

Found in microsomes in liver, kidney, intestine.

In liver, conjugated metabolites typically excreted into bile.

Cats are deficient in glucuronosyl transferase.

Bilirubin is an endogenous substrate.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Glucuronosyl Transferase Substrates

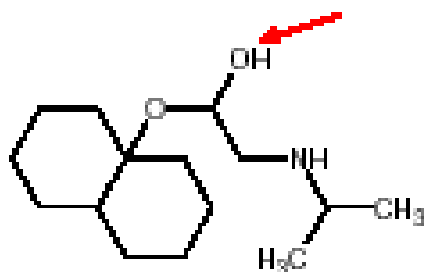

Coumarin

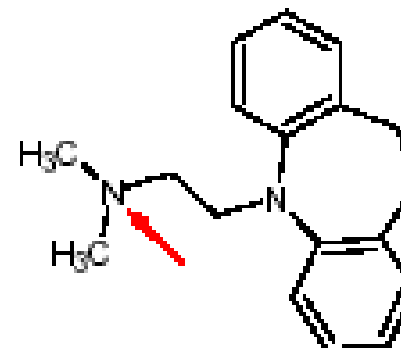

2-Naphthylamine

Thiophenol

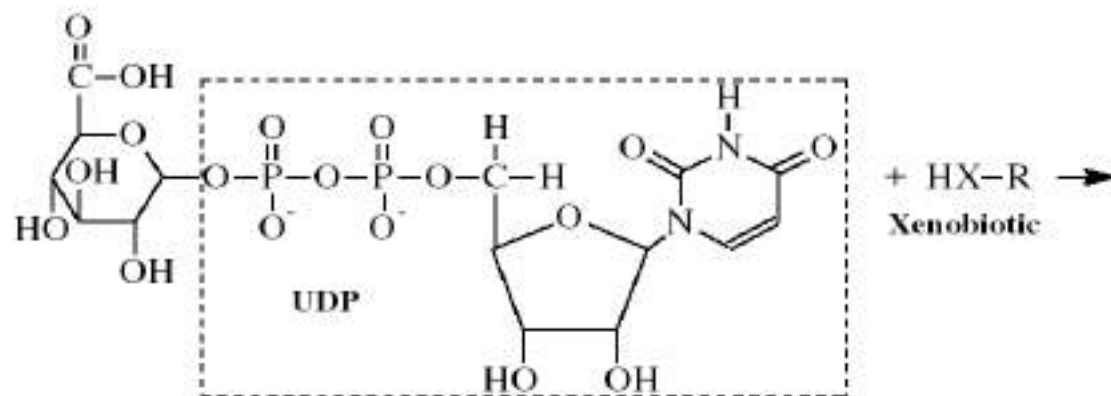

Propanolol

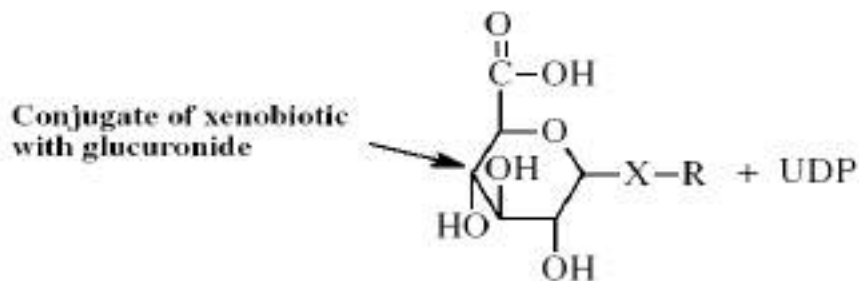

Imipramine

Conjugation by Glucuronides

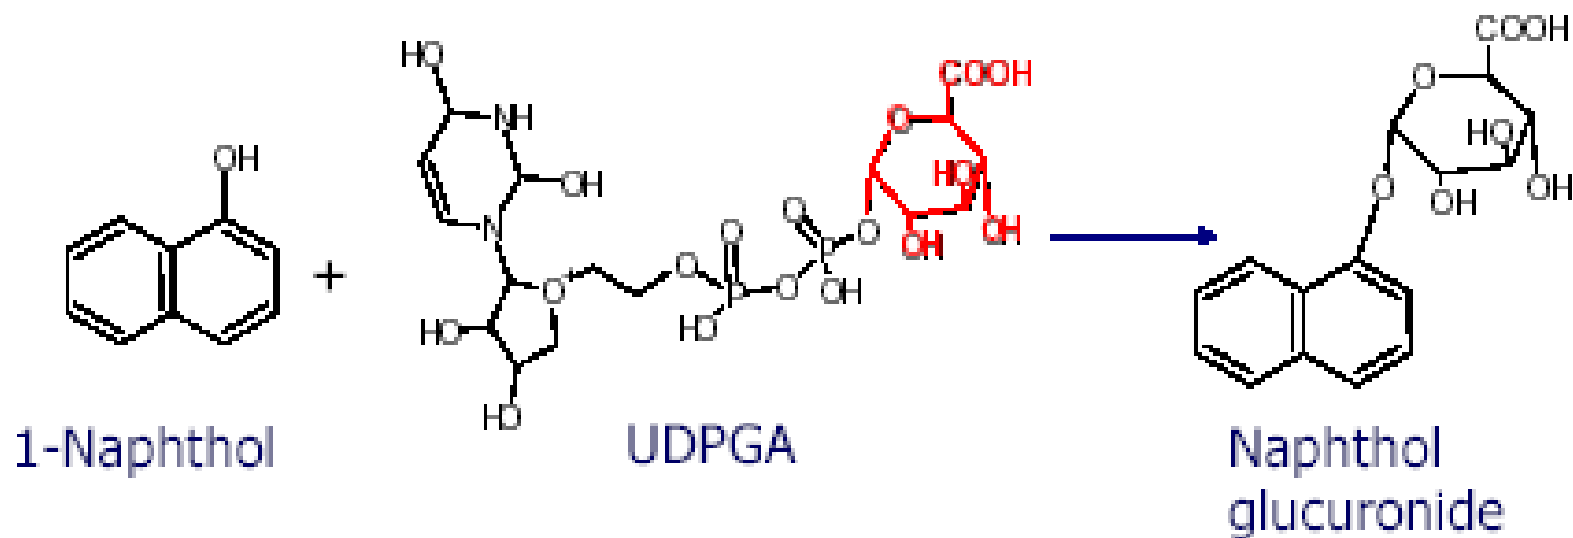

Uridine-5'-diphospho- α -D-glucuronic acid, UDPGA

Conjugate of xenobiotic with glucuronic acid

UDPG transferase reaction sequence

Conjugation by Glutathione

Group transferred glutathione.

Cofactor glutathione (tripeptide - glycine, glutamic acid, cysteine).

Transfer is mediated by glutathione S-transferase enzymes.

Primarily cytosolic dimeric proteins found in liver, some microsomal.

Conjugates with a wide variety of xenobiotic species, including alkenes, alkyl epoxides (1,2-epoxyethylbenzene), arylepoxides (1,2-epoxynaphthalene), aromatic hydrocarbons, aromatic halides, alkyl halides (methyl iodide), and aromatic nitro compounds.

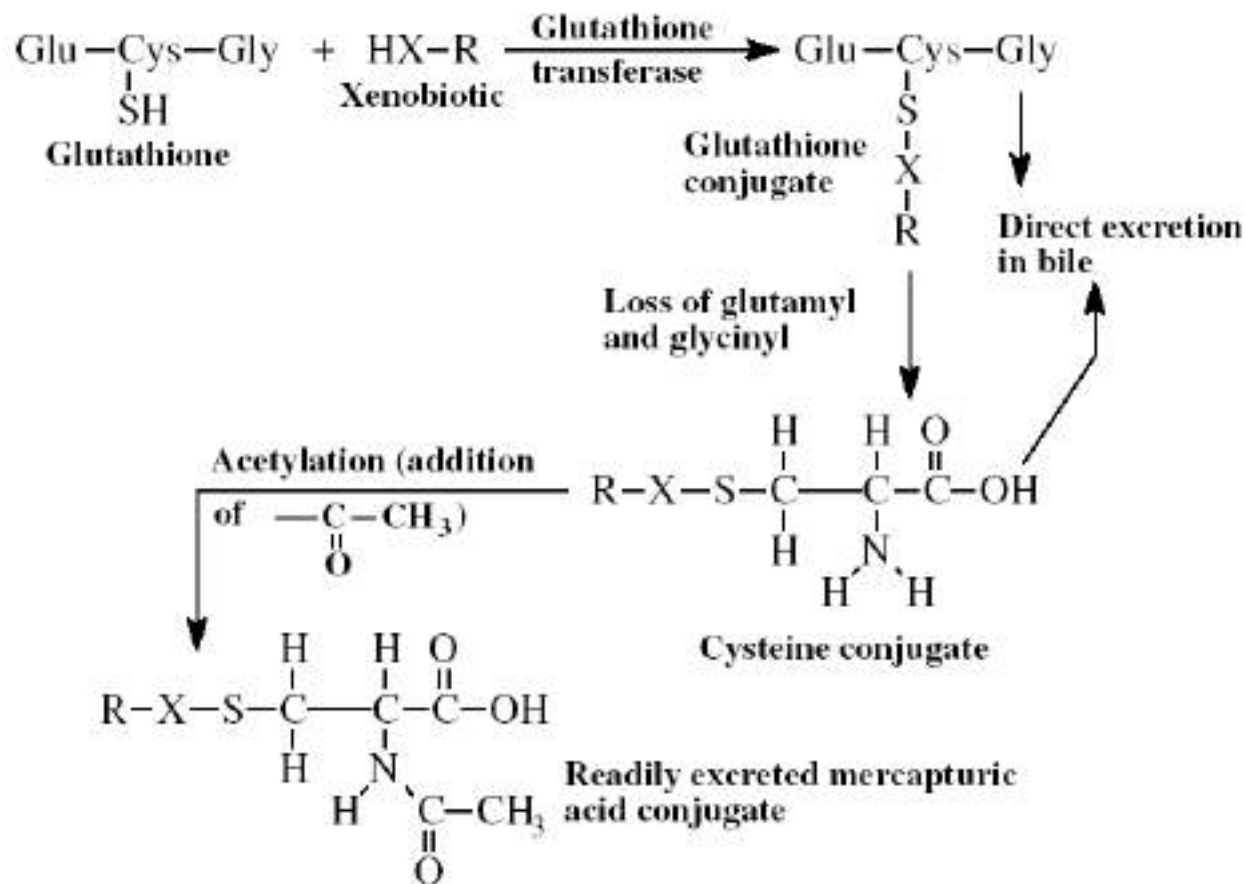

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

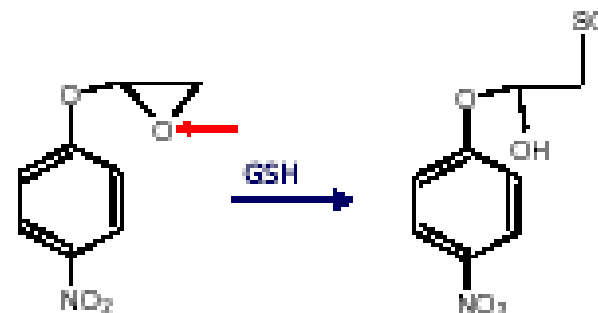

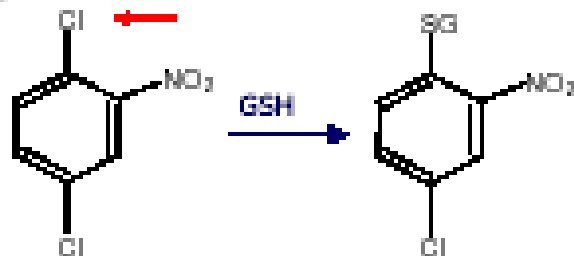

Conjugation by Glutathione

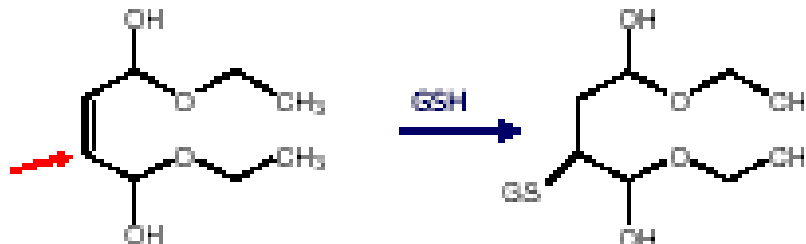

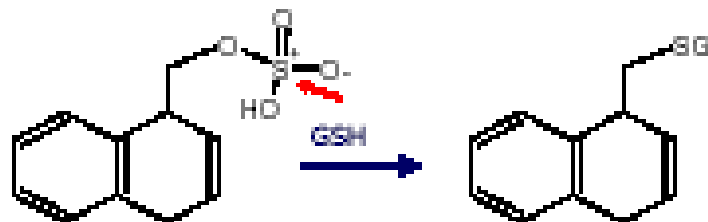

Examples of Glutathione S-Transferase Substrates

1-chloro-2,4 dinitrobenzene

1,2 epoxy-3-(p-nitrophenoxy)propane

1-naphthalene methyl sulfate

diethyl maleate

Conjugation by Sulfate

Group transferred sulfate.

Cofactor PAPS (3'-phosphoadenosine-5'-phosphosulfate).

Types of substrate: phenols, alcohols, aromatic amines.

Transfer is mediated by sulfotransferase enzymes (primary cytosol).

Toxic sulfate conjugate (the sulfate conjugate of N-hydroxyacetyl-aminofluorene is thought to be the proximate carcinogen in the case of this compound).

Pigs and opossums are deficient in sulfate conjugation.

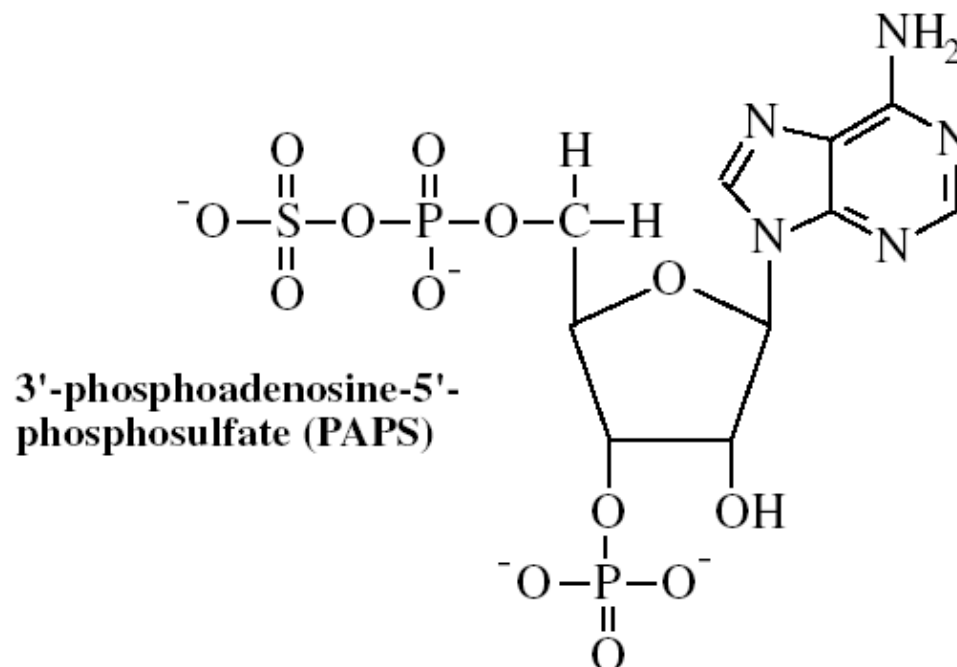

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Conjugation by Sulfate

Structure of PAPS

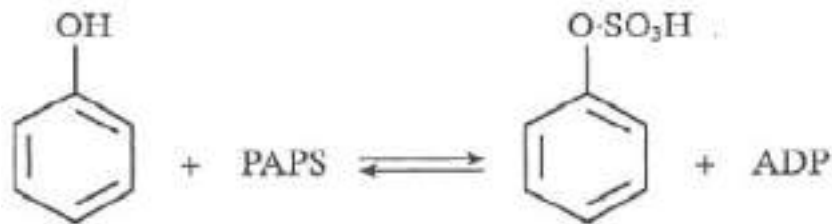

Conjugation by Sulfate

TABLE 6.3 Examples of Sulfate Conjugation to Alcohols, Phenols, and Aromatic Amines.

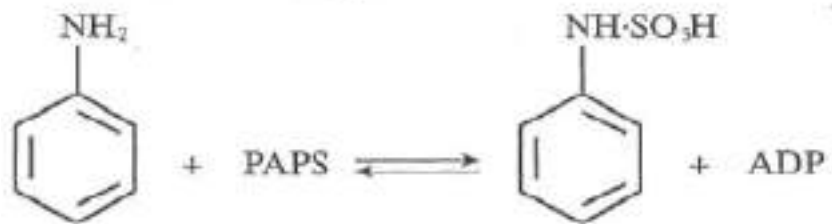

Alcohol conjugation

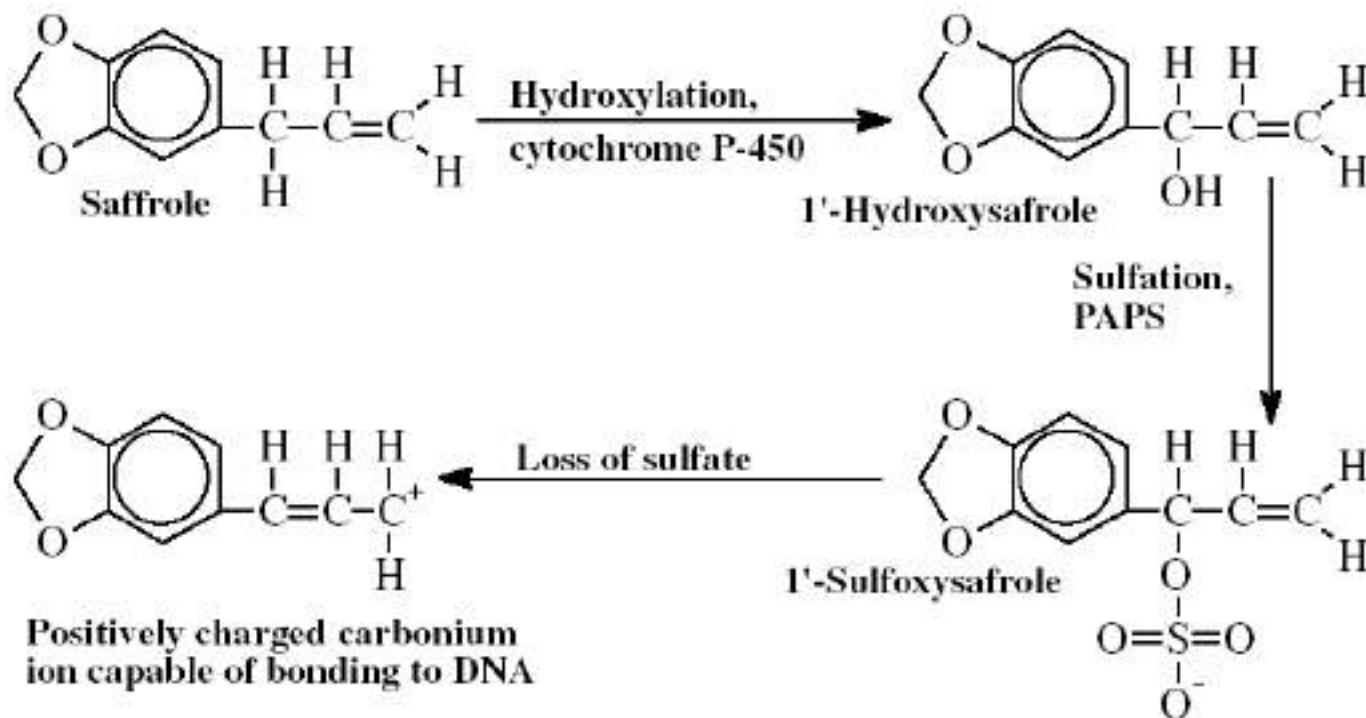

Phenol conjugation

Aromatic amine conjugation

Example of Toxic Sulfate Conjugate

Conjugation by Acetylate

Group transferred acetyl.

Cofactor Acetyl Coenzyme A.

Transfer is mediated by N-acetyltransferase enzymes (primary cytosol).

Types of substrate: amines (amine is converted into amide).

Sometimes acetyl conjugation occurs to detoxify substances (e.g. anilines) that could further produce other harmful metabolites!

Two types of acetylation reactions occur:

- one involves an activated conjugating intermediate, acetyl CoA, and the xenobiotic. The reaction is referred to as acetylation.
- the second type involves the activation of the xenobiotic to an acyl CoA derivative, which then reacts with all amino acid to form an amino acid conjugate.

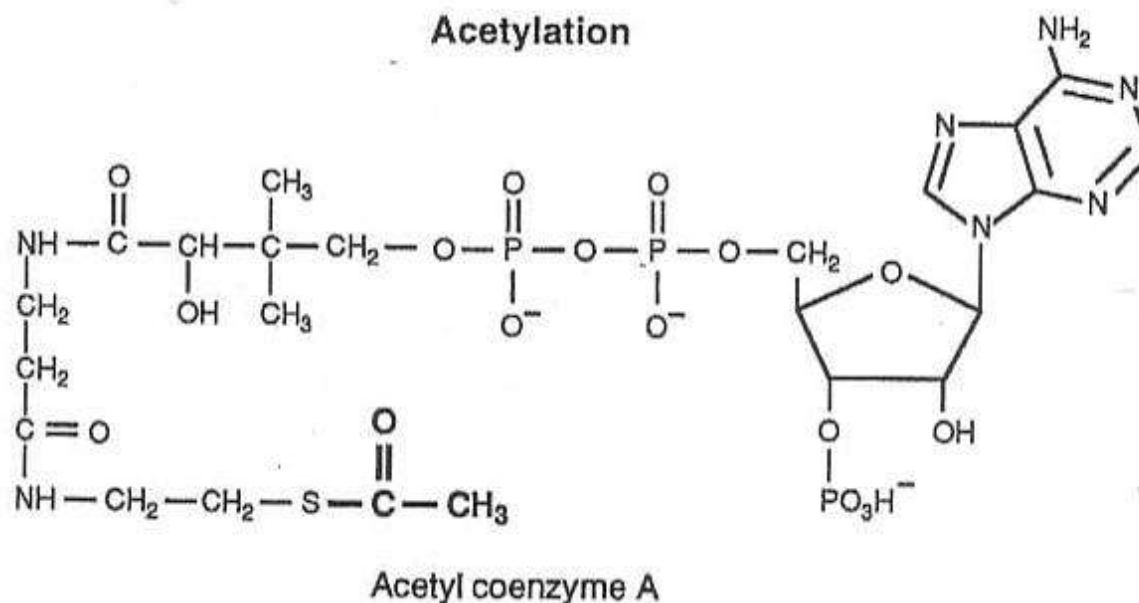

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Conjugation by Acetylate

Structure of Acetyl coenzyme A

Amino Acid Conjugation

Cofactor glycine or glutamine.

Amino acid conjugation occurs for a variety of carboxylic acids and the result is the formation of an amide bond to an amino acid, usually glycine or glutamine.

Transfer is mediated by Acyl CoA glycinetransferase (glutaminetransferase) enzymes (primary mitochondria).

Glycine is the most common conjugating amino acid in mammals.

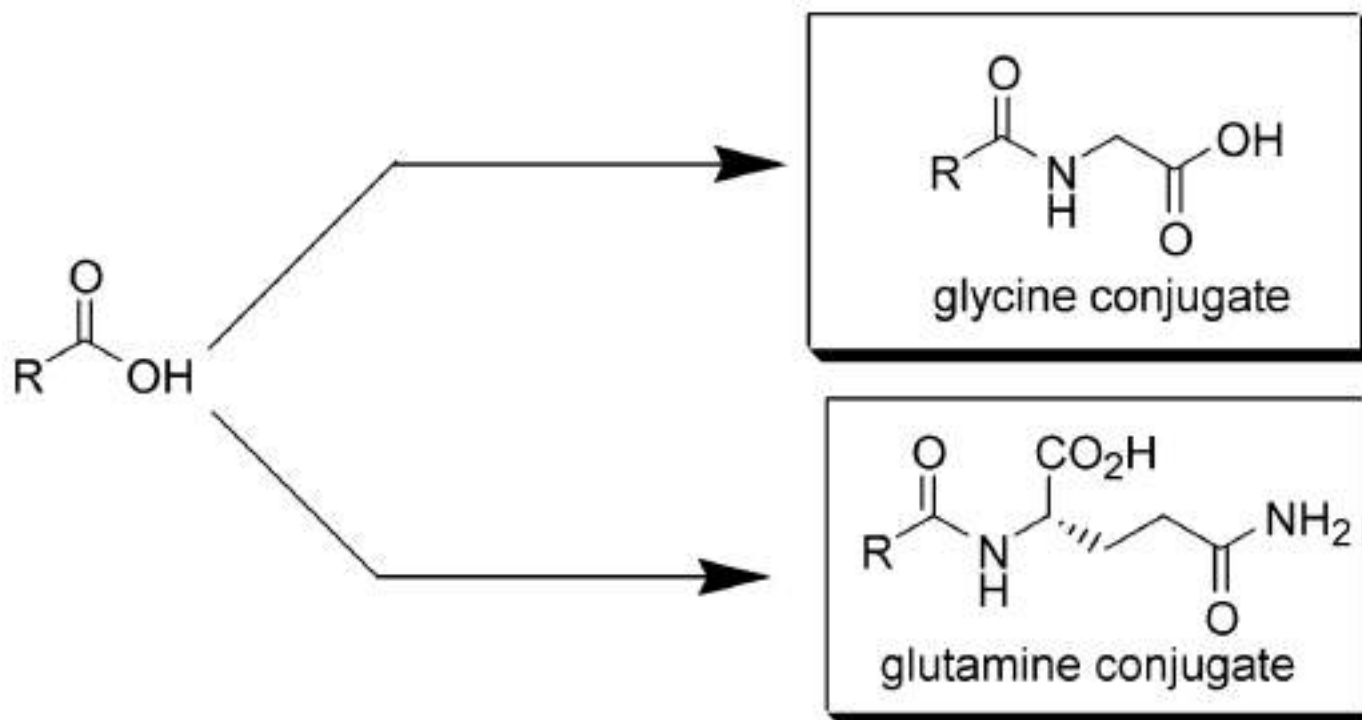

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Amino Acid Conjugation

Amino Acid Conjugation

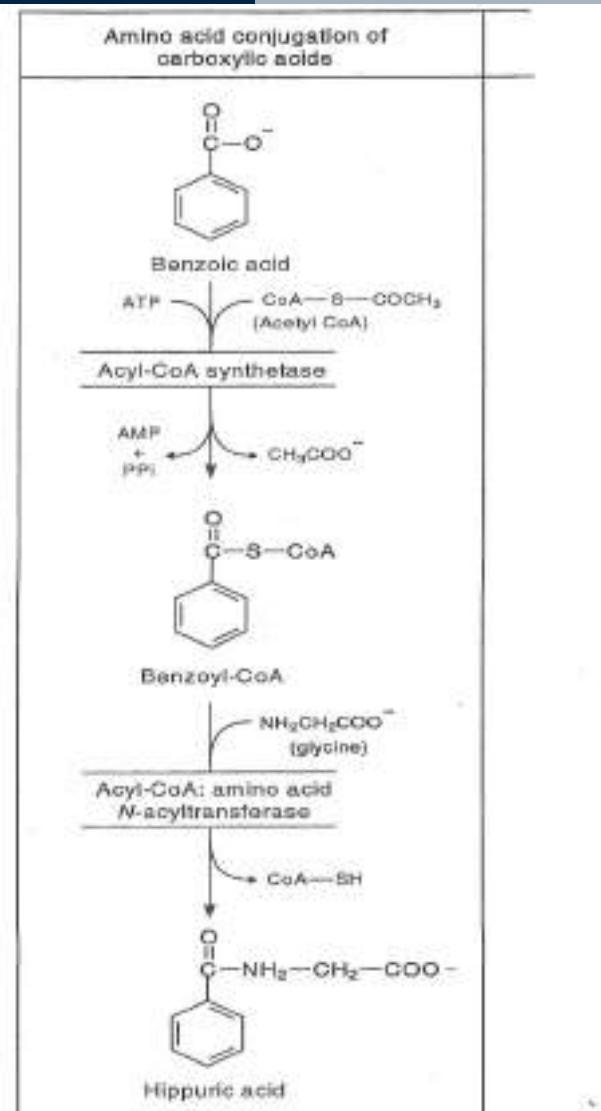

Figure 6-54. Conjugation of xenobiotics with amino acids.

Conjugation by methyl group

Group transferred methylate.

Cofactor S-adenosyl-methionine.

Transfer is mediated by transmethylase (primary cytosol).

Types of substrate: phenols, amines.

It is a common but generally minor pathway of xenobiotic metabolism.

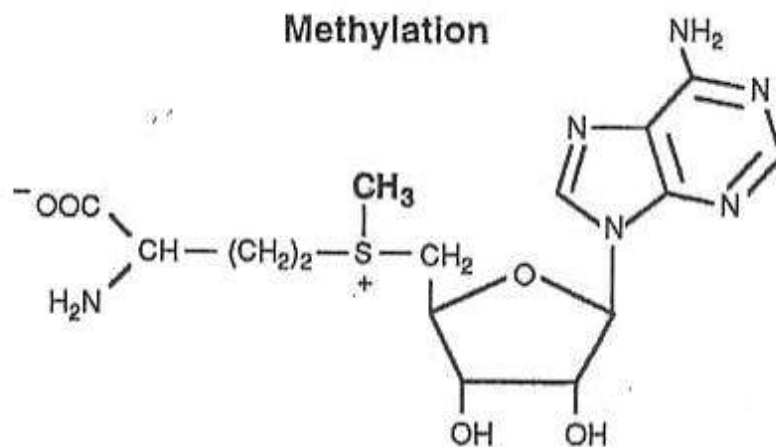

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

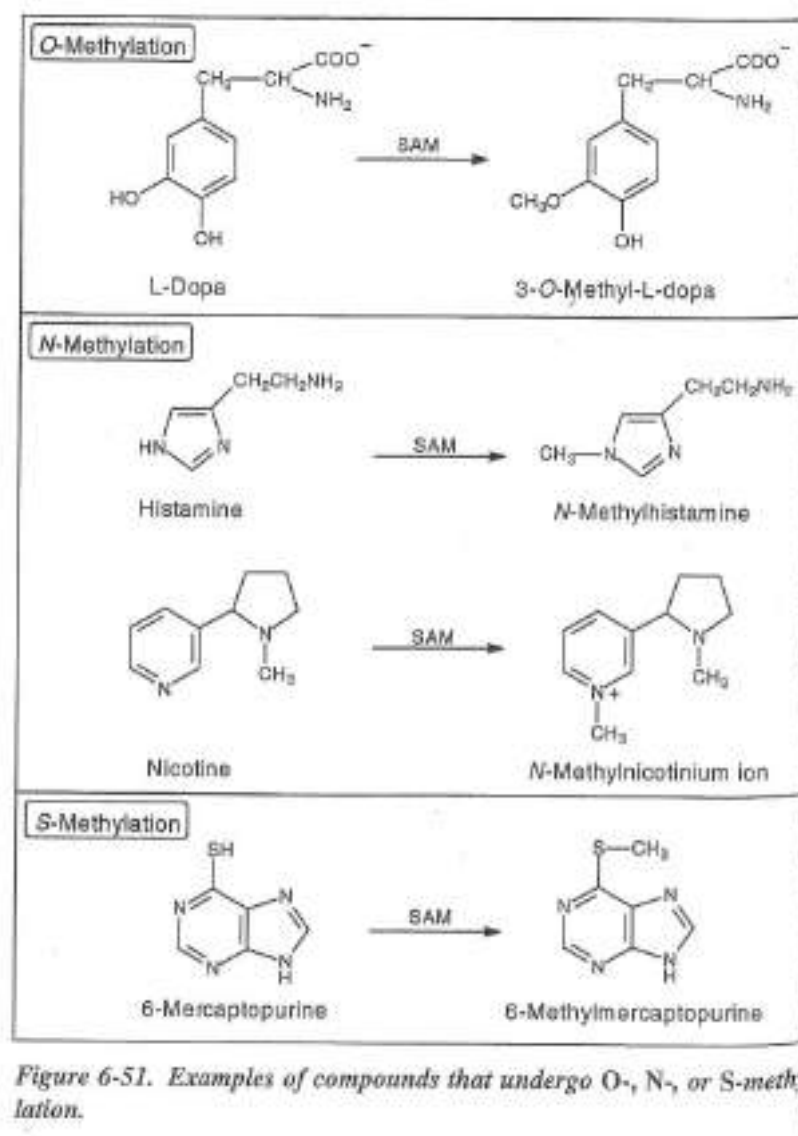

Conjugation by methyl group

Structure of SAM

Conjugation by methyl group

ENZYME INDUCTION

Results from repeated exposure to certain chemical substances.

The result of induction is an increase in the amount of an enzyme or isoenzyme.

Marked increase in rate of metabolism of chemical substance .

Depending on the role of metabolism in the toxicity of a chemical substance therefore, enzyme induction may increase or decrease in the toxicity of the chemical substance.

May also increase the metabolism of other chemical substance taken concurrently.

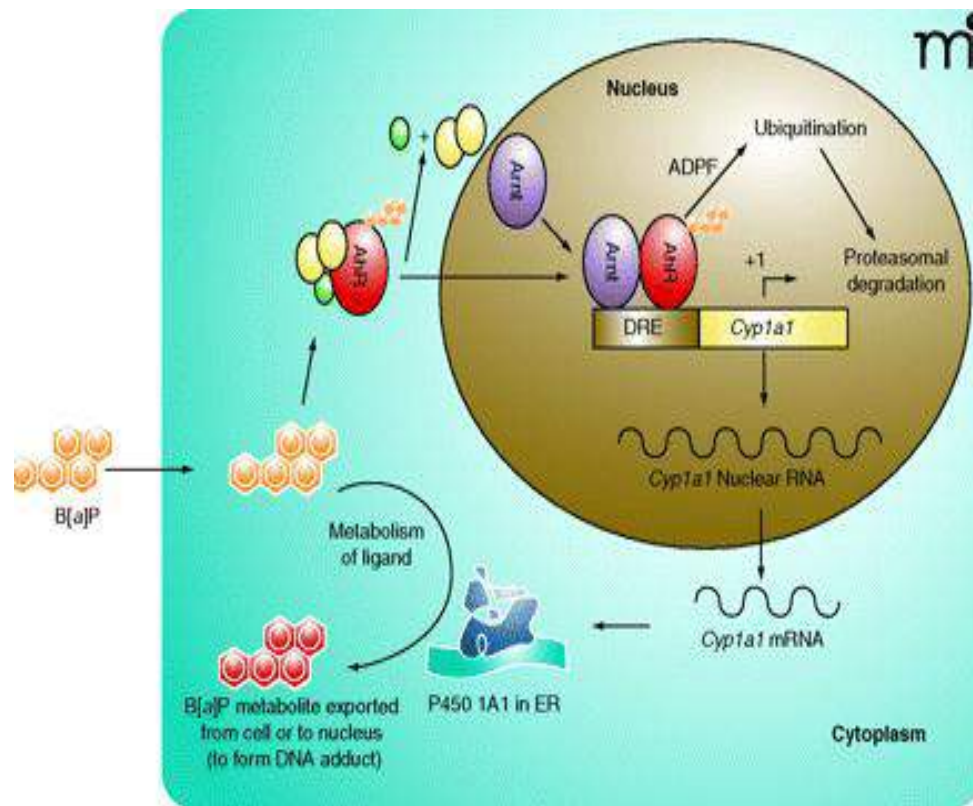

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

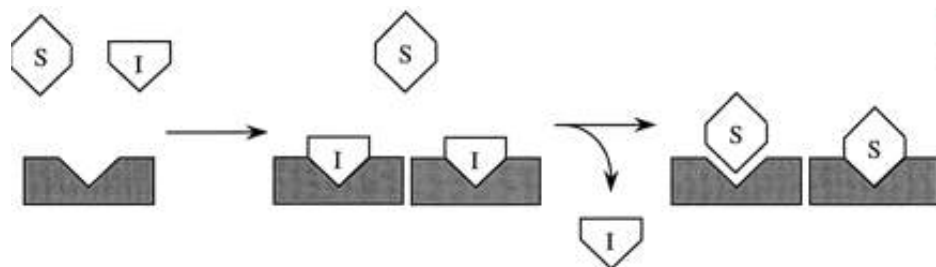

Induction by inducing the biosynthesis of the enzyme

Ah-locus mediated induction

Induction by stabilization

Stabilization of CYP2E1 by active site occupation.

Inducer and substrate are I and S, respectively, and CYP2E1 is represented by the shaded block.

Competitive inhibition of CYP2E1 occurs as the inducer binds to the active site, blocking substrate access.

As a consequence of binding, CYP2E1 accumulates due to stabilization.

As the inducer is removed, substrate regains access to the active site, and the metabolism of substrate is enhanced.

Induction of CYP1A1

TCDD binds to cytosolic AHR, releasing HSP90.

Complex moves to nucleus where it dimerizes with ARNT, exposing DNA binding motif.

Complex binds to DRE in 5'-flanking region of CYP1A1 gene, markedly (100-fold) increasing transcription.

mRNA transported to the ribosome and protein made.

Heme added and protein inserted into ER.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

ENZYME INHIBITION

Some chemical substances can block P450 enzyme isoforms that metabolize other chemical substances (Grapefruit juice - CYP 3A4 inhibitor; fucocoumarins).

Depending on the role of metabolism in the toxicity of a chemical substance therefore, enzyme induction may increase or decrease in the toxicity of the chemical substance.

Unlike induction, enzyme inhibition usually begins with the first dose of the inhibitor.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Enzyme inhibition may be divided into several types involving:

- interaction of the chemical substance with the active site of the enzyme (OP)
- competitive inhibition by two different compounds at the same enzyme active site as with ethylene glycol and ethanol
- destruction of the enzyme as in the case with carbon tetrachloride
- reduced synthesis as with cobalt
- lack of cofactors such as glutathione

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Factors affecting metabolism

1. Chemical substances
2. Genetics variation
3. Nutritional state
4. Dose
5. Age
6. Gender
7. Disease state
8. Route of administration

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Excretion is the process by which a chemical substance or metabolite is eliminated from the body.

Only free unbound chemical substance or metabolite is available for excretion.

Chemical substances are eliminated from the body by various routes.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

EXCRETION URINE - KIDNEY

Renal (kidney) excretion is the primary removal mechanism for chemical substances.

Renal excretion is the result of three processes:

- passive glomerular filtration
- active tubular secretion in proximal tubules
- passive tubular re-absorption (diffusion)

Unchanged- metabolites

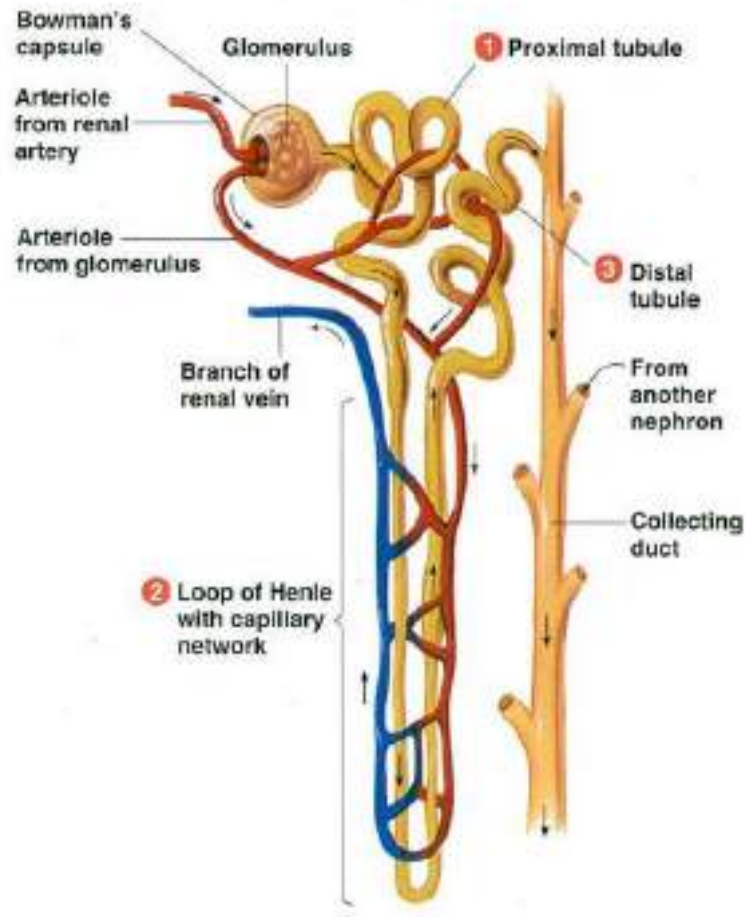

⇒ relatively small (< 100 molecular weight), water soluble

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Detailed structure of a nephron

EXCRETION URINE - KIDNEY

INFLUENCING FACTORS

- ⇒ urinary pH (change in urinary pH affect excretion)
- ⇒ rate of urinary flow
 - ↑ high fluid intake ⇒ ↑ facilitate excretion
- ⇒ kidney function
 - age, disease, simultaneous administration of other damaging compound
 - ⇒ functional – morphological changes
 - ↘ ↓ elimination

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

EXCRETION BILE - LIVER

The liver is the main site of biotransformation of chemical substances, the metabolites may be excreted directly into bile.

⇒ large, polar substances (> 300 molecular weight)

COMPOUND	Molecular weight	% of total excretion	
		urine	faeces
Biphenyl	154	80	20
Monochlorobiphenyl	188	50	50
Dichlorobiphenyl	223	34	66
Pentachlorobiphenyl	326	11	89
Hexachlorobiphenyl	361	1	99

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

EXCRETION BILE - LIVER

⇒ active gland process

⇒ may be saturated

Once a compound is excreted into bile and enters the intestine, it can be eliminated with feces.

colon (Hg, Fe, Bi)

saliva (Hg, Bi)

⇒ contact with gut bacteria

⇒ more lipid soluble compounds ⇒ reabsorption

⇒ enterohepatic circulation

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

EXCRETION LUNGS

Chemical substances that exist predominantly in the gas phase at body temperature are excreted by the lungs.

Volatile liquids in equilibrium with their gas phase may also be excreted via the lungs. Elimination of foreign gases is nearly inversely to the rate of gas uptake. Gases with low solubility in blood are rapidly excreted.

⇒ chemical substances are eliminated by diffusion from the blood into the alveolus

⇒ characteristic odor

cyanide	→ almond
phosphorous	→ garlic
hemlock	→ mouse-like

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

EXCRETION GIT

Appearance of chemical substances in feces can be due to a number of factors:

- the chemical substance was not completely absorbed after oral ingestion
- it was excreted into bile
- it was secreted in saliva, in gastric or intestinal secretory fluid, or in pancreatic secretion
- it was secreted by the respiratory tract and then swallowed

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

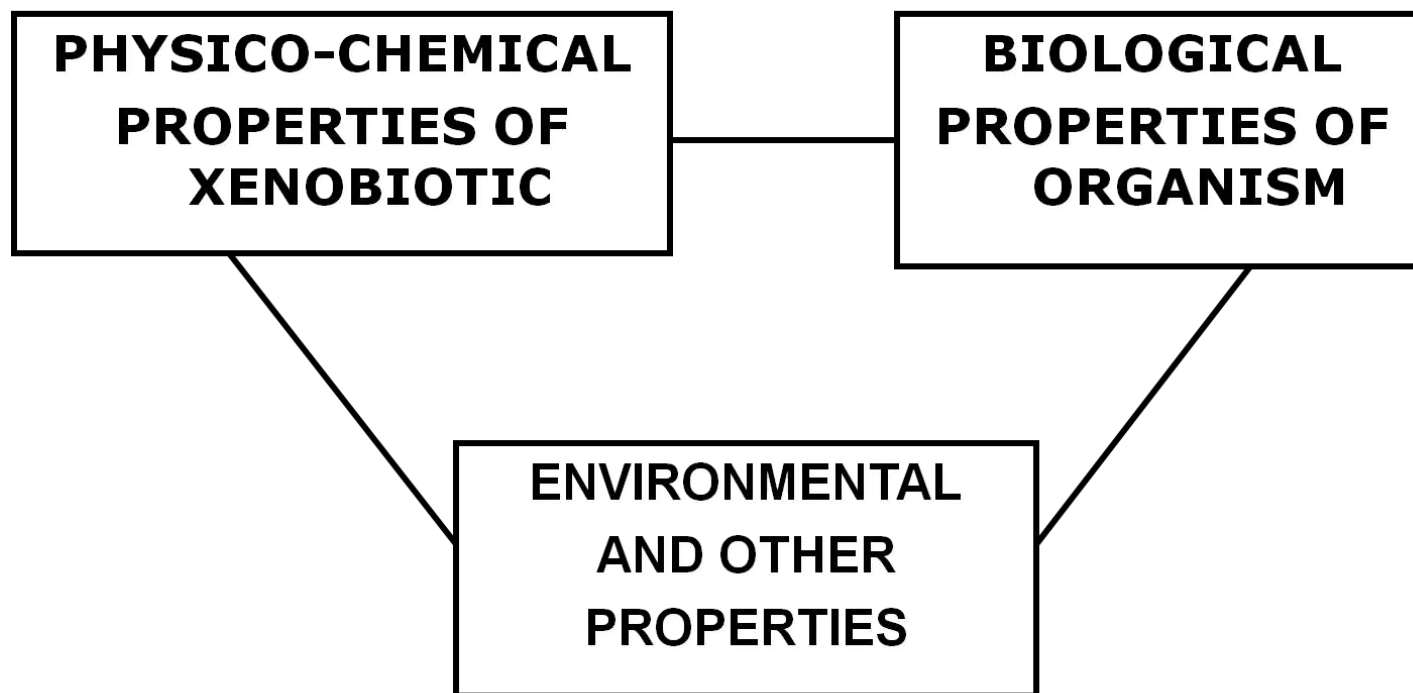

EXCRETION MILK

- ⇒ lipid soluble compounds (OC, dioxin, PCB, Se, As)
- ⇒ poisoning source
 - ⇒ nursing child
 - ⇒ food-toxicological importance ⇒ **PUBLIC HEALTH!**

EXCRETION EGG

- ⇒ lipophilic ⇒ egg yolk
- ⇒ hydrophilic ⇒ white of egg
- ⇒ **PUBLIC HEALTH PROBLEMS !**
- ⇒ **EXTINCTION OF WILD BIRDS !**

Factors influencing toxicity

I. PHYSICO-CHEMICAL PROPERTIES OF CHEMICAL SUBSTANCES

1. LIPOPHILICITY

Major importance for absorption + other phases of disposition

⇒ lipophilic ⇒ more readily absorb across membrane
⇒ more readily able to distribute

BUT ! excretion (kidney) ⇒ water solubility

major factor in toxicity ⇒ special membrane

2. MOLECULAR SIZE AND WEIGHT

Also of great importance in each phase of disposition

ABSORPTION

Small lipophilic molecule (generally, GI, skin)

Factors influencing toxicity

2. MOLECULAR SIZE AND WEIGHT

EXCRETION

Determine route of excretion

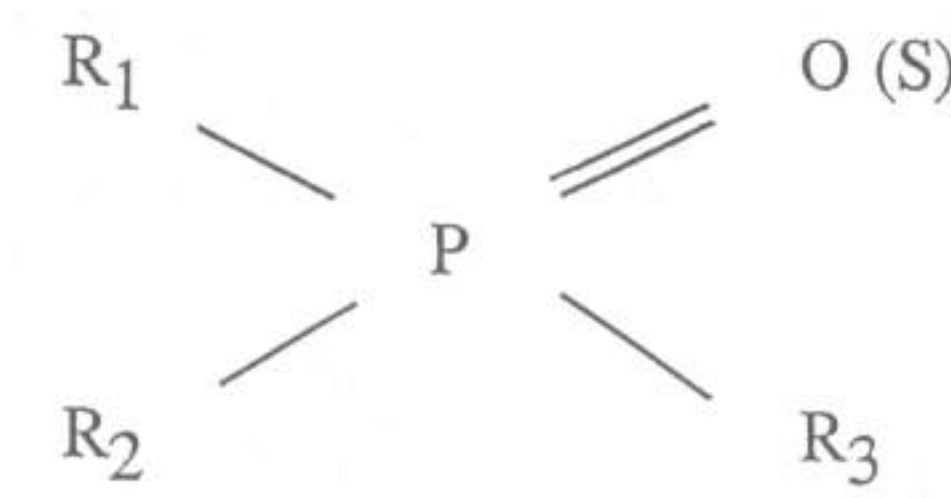

Chemical substance	Molecular weight	Rate of excretion (%)	
		urine	faeces
Biphenyl	154	80	20
Monochlorobiphenyl	188	50	50
Dichlorobiphenyl	223	34	66
Pentachlorobiphenyl	326	11	89
Hexachlorobiphenyl	361	1	99

3. CHEMICAL STRUCTURE

CHANGES OF STRUCTURE

minor changes \Rightarrow modify biologic action, toxicity

♦ Organophosphates O \uparrow - S \downarrow

3. CHEMICAL STRUCTURE

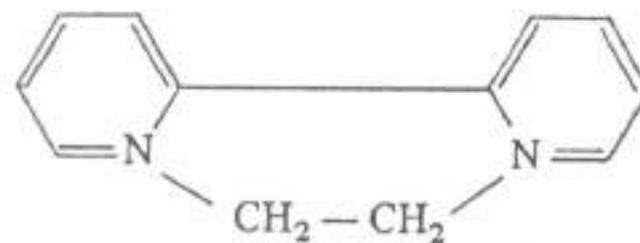

CHANGES OF STRUCTURE

♦ Bipiridyl

paraquat \rightleftharpoons diquat

Paraquat

Diquat

3. CHEMICAL STRUCTURE

CHANGES OF STRUCTURE

Allotropic

yellow phosphorous ✓ \Leftrightarrow red phosphorous Ø

Isomerization

ciss \Leftrightarrow trans (resmethrin)
LD₅₀ : 100 8000 mg/kg b.w.

4. IONIZATION

degree of ionization

⇒ basically affects toxicity

- ♦ non-ionized ⇒ lipophilic
- ♦ ionized ⇒ hydrophilic

MODIFY MEMBRANE TRANSPORT

QUICKEN the ELIMINATION

- ♦ salicylic acid-derivatives
dissociated in alkaline pH ⇒ Ø reabsorption
- ♦ strychnine (alkaloids), barbiturates
acidification ⇒ Ø reabsorption

II. BIOLOGICAL PROPERTIES OF ORGANISM

1. SPECIES

ANIMAL SPECIES	RELATIVE SENSITIVITY
Man	1.0
Horse, swine	0.5
Cattle, sheep, goat	0.3
Dog	0.2
Rat	0.1

Factors influencing toxicity

1. SPECIES

SENSITIVITY

thalidomide animal ⇔ human

DIOXIN

ANIMAL SPECIES	LD ₅₀ (mg/kg)
Guinea-pig	0.5-2
Rat	22-100
Mouse	114-284
Rabbit	10-115
Chicken	25-50
Rhesus monkey	< 70
Dog	> 30-300
Hamster	5051

Factors influencing toxicity

1. SPECIES

ANATOMICAL differences

GI length and parts of GI

dog short, efficient digestive tract
absorption more rapid, completed
> herbivora

SKIN cat > dog
more permeable to OP

VOMITING !!!

horse, rat, rabbit \Rightarrow unable to vomit
anatomical – physiologic \Rightarrow
 \Rightarrow toxic effect \uparrow

1. SPECIES

PHYSIOLOGIC differences

plant \Rightarrow ruminants \emptyset

metals \Rightarrow ruminants \uparrow

gase \Rightarrow birds \uparrow

kidney capacity: \downarrow bird $<$ mammals

CAT \Rightarrow METABOLISM differences

Factors influencing toxicity

1. SPECIES

METABOLISM

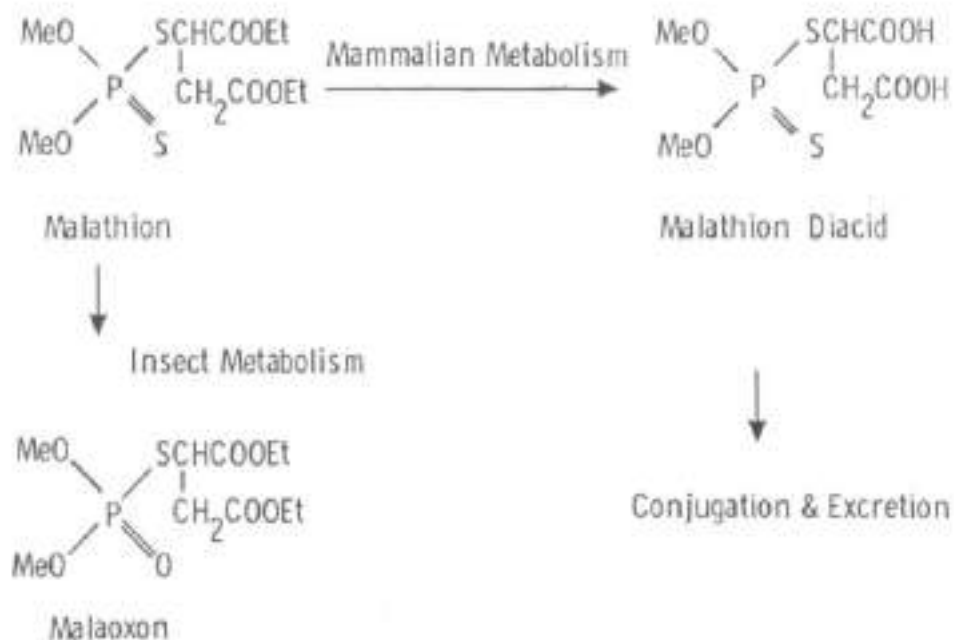

„relative” deficiency – enzyme deficiency

SPECIES	PHENOL CONJUGATION (% total)	
	GLUCURONIDE	SULFATE
CAT	0	87
Man	23	71
Rat	25	68
Rabbit	46	45
Guinea-pig	78	17
SWINE	100	0

Factors influencing toxicity

1. SPECIES

METABOLISM

Factors influencing toxicity

1. SPECIES - STRAIN

OP Brahman cattle > Hereford cattle

Thiourea i.p. LD₅₀ (mg/kg)
rat strains

Hopkins: 4 < Harward: 44 < Norway rat: 1340-1840

2. SEX

MALES

metabolize more rapidly

⇒ results in lower toxicity

⇒ metabolize ⇒ more toxic metabolite

⇒ higher toxicity

Factors influencing toxicity

3. AGE

YOUNG – GERIATRIC individuals

- ⇒ more sensitive
- ⇒ metabolizing activity
- ⇒ plasma-protein binding capacity
less efficient

parent chemical ⇒ more toxic

! Converse is also true

require metabolic activation for toxicity

⇐ less toxic

4. HEALTH STATUS

LIVER, KIDNEY function

hepatic/renal disease ↑ susceptibility

CONDITION

fat tissue ⇒ storage ⇔ toxicity ↓
 ⇐ starvation ⇔ lipolysis ↑
 ⇐ re-distribution (OC)
 + toxicity ↑

III. ENVIRONMENTAL AND OTHER PROPERTIES

1. FOOD - WATER

Composition – nutritional status

⇒ influence disposition, toxicity

DISADVANTAGE

HIGH FAT (LIPID)-content

⇒ dissolving, absorption ↑

1. FOOD - WATER

DISADVANTAGE

- ♦ **PROTEIN INSUFFICIENCY diet**
 - ⇒ ↓ microsomal enzyme activity
 - ⇒ ↓ level of plasma proteins (binding)
- ♦ **MINERAL/VITAMIN DEFICIENCY**
 - ⇒ ↓ metabolism
- ♦ **STARVATION**
 - ⇒ ↓ supply of essential cofactors (sulphate, glutathione)

1. FOOD - WATER

DISADVANTAGE

- ♦ WATER

- ⇒ insufficient – deprivation

- ↑ possibility of poisoning (NaCl)

- ⇒ source of poisonings

- fertilizers, industrial emission etc.

Factors influencing toxicity

2. ENVIRONMENT

TEMPERATURE ↓

SUNSHINE – DIRECT SUNLIGHT ↓
facilitate the degradation (OP)

HUMIDITY ↓
destroy during storage

pH ↑ ↓

MICROBIAL ACTIVITY ↑ ↓

Definition of Teratology

The study of abnormal development in embryos and the causes of congenital malformations or birth defects.

- Structural malformation
- Growth retardation
- Functional disorder
- Death of the organism

TÁMOP-4.1.2.A/2-10/1-2010-0012

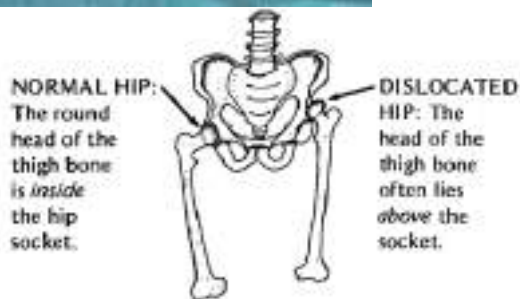

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Congenital Dislocation (Dysplasia) of the Hip in an Infant

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Malformation

Congenital malformation are structural defects present at birth. They may be gross or microscopic, on the surface of the body or within it, familiar or sporadic, hereditary or nonhereditary, single or multiple. (Warkany, 1947).

A major congenital anomaly is one that is incompatible with survival, is life-threatening, or seriously compromises an individual's capacity to function normally in society (Otake et al., 1990).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Growth retardation

Functional disorders

- Inborn errors of metabolism
- Physiological disturbances
- Mental retardation
- Cellular and molecular abnormalities

Teratogenicity

Congenital defects are the #1 cause of death in infants.

Observed in 3% of newborns.

Observed in another 3% of children later.

May or may not be outwardly visible.

Etiology: genetic and environmental.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Factors influencing teratogenicity

- Genetic susceptibility
- Gestational timing
- Frequency and duration of exposure
- Nature of the agent (specificity)
- Dose

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Genetic susceptibility

Different in genotype \Rightarrow different in sensitivity

– species, breed, phylum...

- Differences in metabolic pathways and products.
- Anatomical differences (humans 1, rodents and rabbits 2).

Acetylsalicylic acid (humans \emptyset , rodents ✓).

Thalidomid (humans ✓ , rodents \emptyset).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Gestational timing

The total period of intrauterine development can be divided into three parts.

1. Preimplantation

- Begins when egg is fertilized in the fallopian tube.
- Period of rapid cell division.
- Ends 2 weeks later when the zygote is implanted in the wall of the uterus.
- „All or none” phenomenon. („All” → early abortions, „None” → reorganisation (cell division) → healthy newborn.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Gestational timing

2. Organogenesis

- From 3 to 8 weeks after conception.
- Body parts are formed during this period.
- In general it can still be said that this period is one of great vulnerability. The teratogens can damage the embryo, leading to defective development or even death. Each organ system also has its own critical period when it is most vulnerable.
- The period of maximum sensitivity to a teratogen corresponds to the 'critical period of organogenesis: during early organogenesis, malformations of the CNS, eyes and limbs occur; later in organogenesis, the ears, external genitalia, teeth and palate are affected.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Gestational timing

3. Foetogenesis (foetal development)

- From 9 weeks after conception to birth.
- Increase in size and systems begin to function.
- This is the longest part of prenatal development. The foetus becomes less susceptible to teratogenic effects.
- During subsequent histogenesis and functional maturation, structural tissue defects and/or functional loss (growth/CNS abnormalities and behavioural effects), plus growth retardation as a consequence of general cell necrosis are common.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Gestational timing

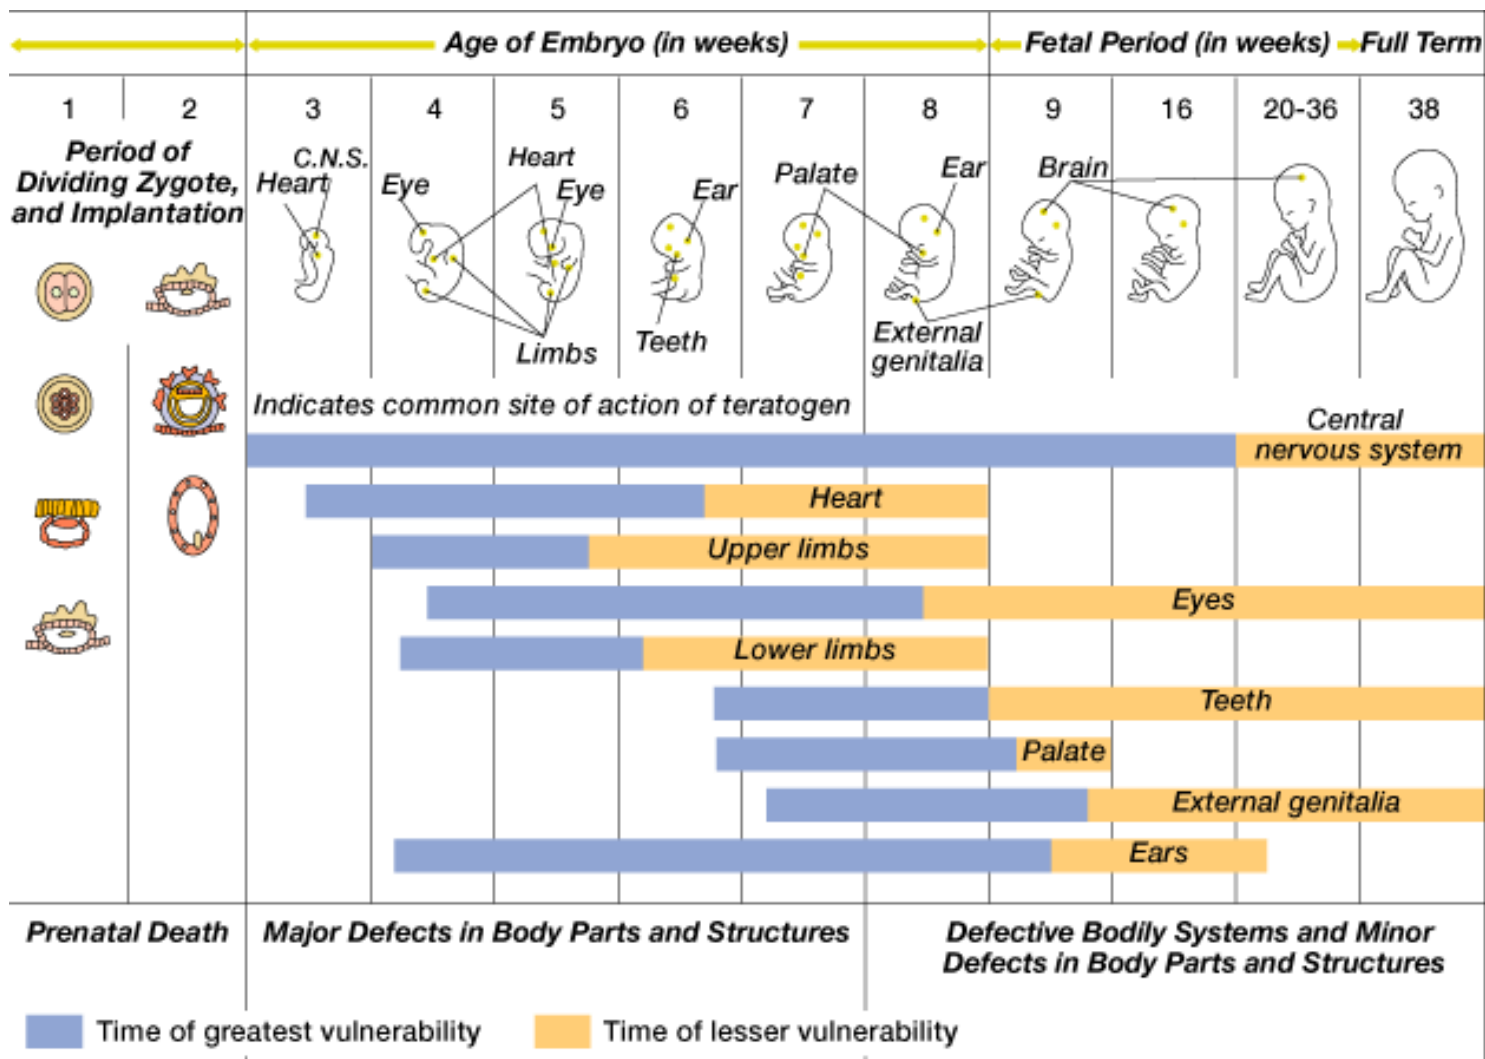

Main parts of intrauterine development	Rat	Rabbit	Humans
Preimplantation	5-6 days	5-6 days	6-8 days
Organogenesis	8-9 days	12-14 days	50-60 days
Foetogenesis	6-8 days	13-15 days	200- 220 days

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Frequency and duration of exposure

In case of a continuous exposure of a teratogenic agent the abnormalities, connecting with the main parts of intrauterine development appear cumulatively.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Nature of the agent (specificity)

The site of action of the teratogens are different in the organism.

⇒ different types of teratogens

⇒ similar abnormalities → given during the same critical period

⇒ same teratogens

⇒ at different times → different effects

Thalidomid – phocomelia

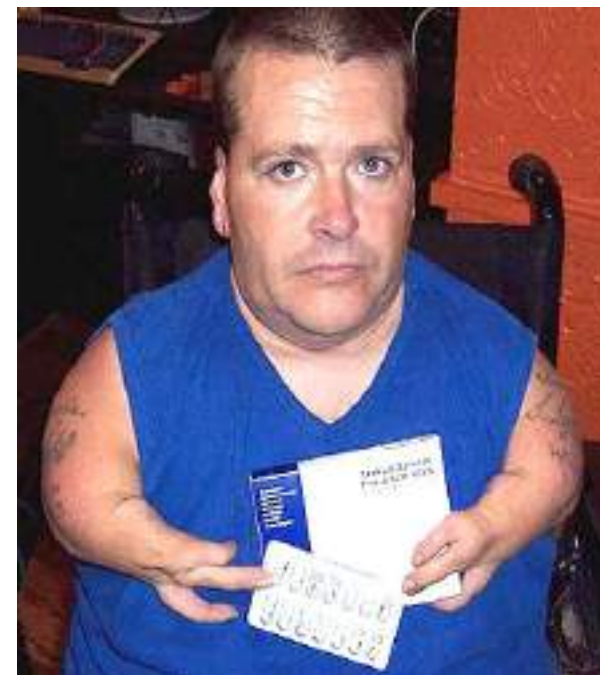

Hypervitaminosis A – spina bifida, eye deformities, cleft palate

Warfarin – skeletal and CNS abnormalities

Alkohol – FAS

Teratogenicity

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Befektetés a jövőbe
Új Magyarország
FEJLESZTÉSI TERV

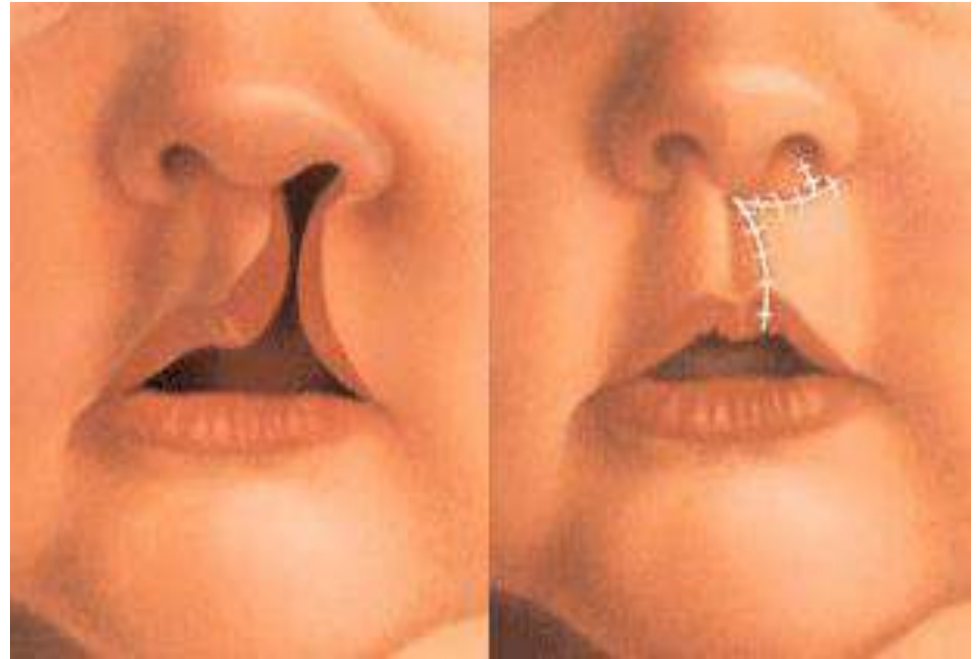

Teratogenicity

Unilateral cleft lip & palate

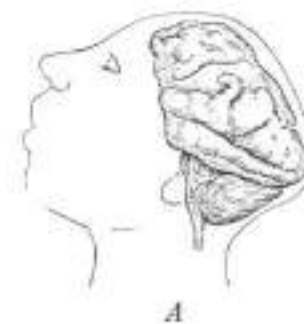

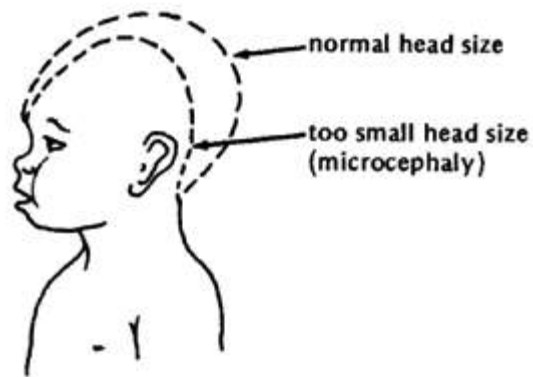

Bilateral cleft lip & palate

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

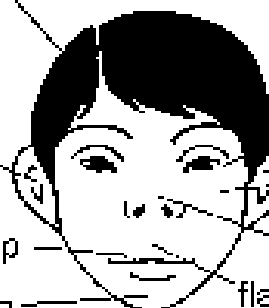

Normal

small head circumference

simply formed
low-set ears

thin upper lip

small chin

FAS

smaller eye openings
under eye folds

flat midface

short, upturned nose

flat, elongated philtrum
(grooves above lip)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Befektetés a jövőbe
Új Magyarország
FEJLESZTÉSI TERV

Dose

Exposures to teratogenic agents only result in teratogenic effects when a certain threshold dose has been exceeded.

For every teratogen there is a level of exposure below which no adverse effect to the embryo occurs, known as the 'no observable effect level' (NOEL); above this threshold, teratogenic effects steadily increase in a dose-response relationship.

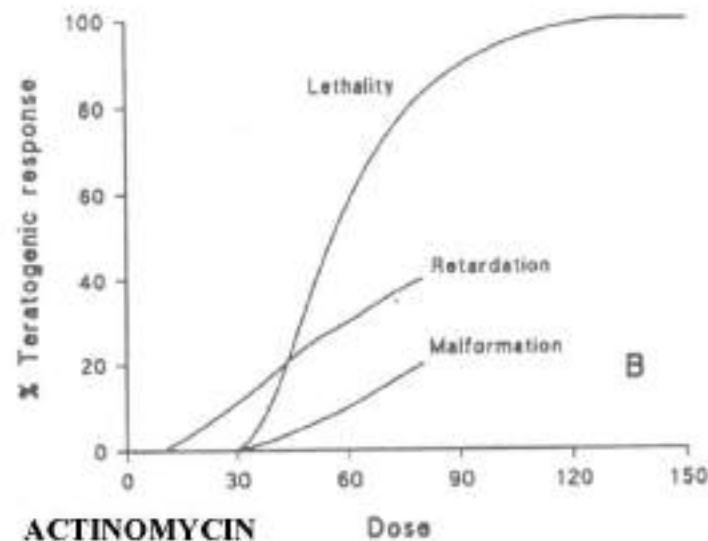

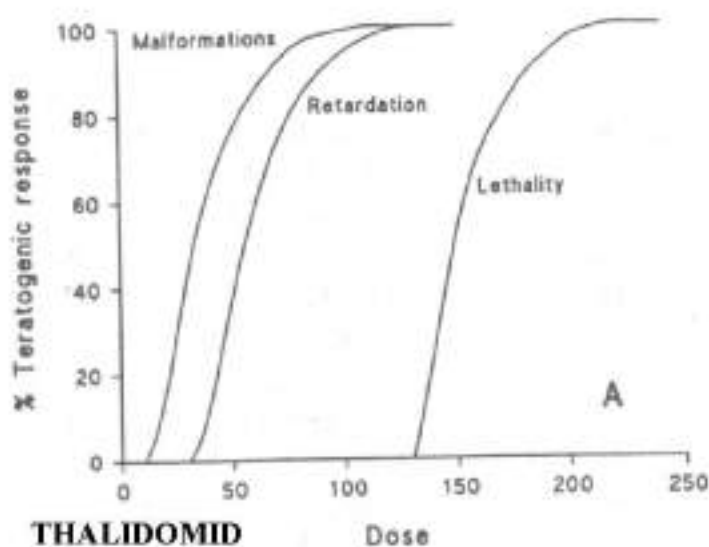

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Increasing doses

– ineffective → teratogenic effect (malformation, growth retardation) → fatal to embryo → maternal toxicity → fatal to mother.

Karnofsky's Law:

„ Anything can be teratogenic if given in the right dose, to the right species, at the right time.”

This may well explain the inclusion of various everyday substances, which are essential for life itself, in the list of teratogens in 'Dangerous Properties of Industrial Materials@ (Lewis, 1989). These include drinking water (Turbow *et al.*, 1971) and table salt (Nishimura and Miyamoto, 1969); oxygen; sugars in the form of sucrose and lactose; palm oil, corn oil and nutmeg oil; other naturally occurring food constituents such as cholesterol and papain (prevalent in pineapples); vitamins such as A, D2, K, B7 and B12 (the B vitamins are frequently found in pregnancy supplements); naturally occurring and essential hormones such as estradiol, progesterone and various prostaglandins; the amino acid methionine, and the DNA constituent adenine.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

CAUSES OF CONGENITAL MALFORMATIONS

I. Anomalies caused by genetic factors (~20%)

- Chromosomal abnormalities
- Single gene defects

1. Chromosomal abnormalities

- Numerical chromosomal abnormalities

Down syndrome (21), Edwards (18), Patau (13), Turner (X0), Klinefelter (XXY).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Down syndrome is caused by non-disjunction of the 21st chromosome during meiosis. As a result, the child has three 21st chromosomes instead of the normal two. Symptoms: characteristic facial features, congenital heart disease, growth retardation, and mental retardation.

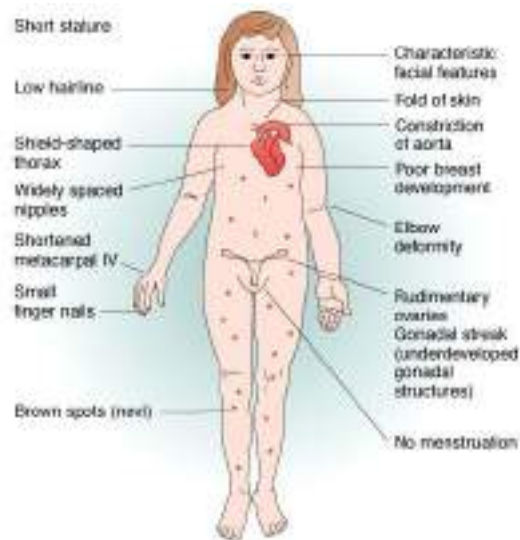

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Monosomy of the X-chromosome is referred to as **Turner syndrome**. Turner syndrome is a rare, exclusively female disease. Because Turner syndrome affects one of the X chromosomes in women, girls affected with this condition often also experience delayed and underdeveloped sexual characteristics, as well as infertility.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

1. Chromosomal abnormalities

- Structural chromosomal abnormalities

translocations (exchange of material between chromosomes), inversions, deletions or duplications - Cri du chat syndrome.

2. Single gene defects

Achondroplasia, Fragile-X syndrome.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

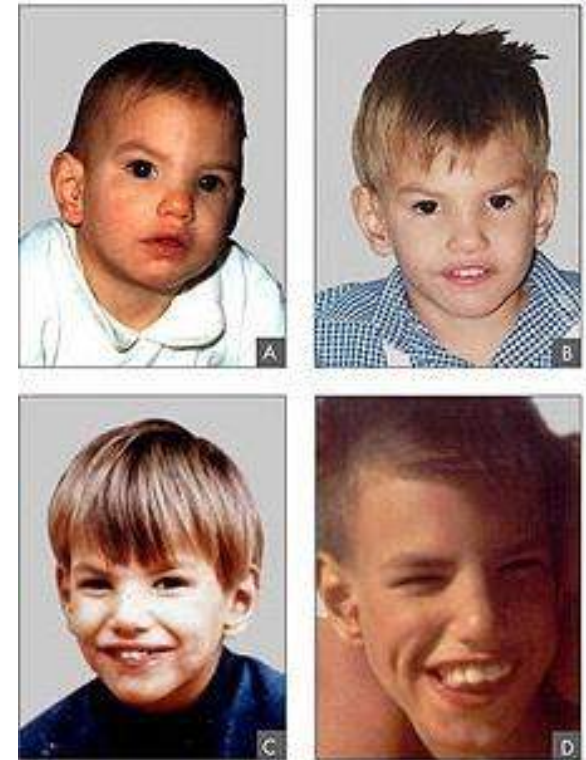

Teratogenicity

Cri du chat syndrome is one of the more common deletion syndromes, involving the short arm of chromosome 5.

The syndrome gets its name from the characteristic cry of affected infants, which is similar to that of a meowing kitten, due to problems with the larynx and nervous system.

Other symptoms: low birth weight and poor growth, behavioral problems such as hyperactivity, aggression, unusual facial features which may change over time.

Facial features of a child with Cri du Chat syndrome at age of 8 months (A), 2 years (B), 4 years (C) and 9 years (D).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Achondroplasia is a disorder of bone growth.

All persons with achondroplasia are little people. The average height of an adult with achondroplasia is 131 cm in males and 124 cm in females.

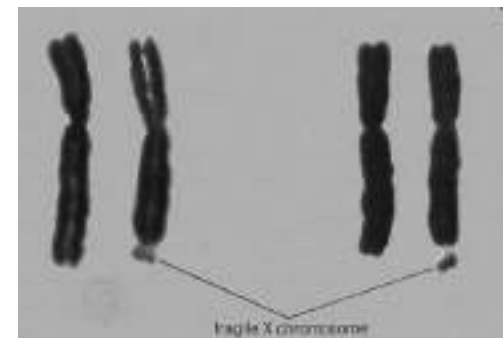

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Fragile X syndrome is associated with the FMR1 gene, which is on the X chromosome. Mutations in the FMR1 gene cause fragile X syndrome. The FMR1 gene provides instructions for making a protein called fragile X mental retardation 1 protein. This protein likely plays a role in the development of synapses, which are specialized connections between nerve cells.

- The severity of the condition varies and a child may have slight learning disabilities, autism or severe mental retardation.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

II. Anomalies caused by environmental factors (3-9%)

1. Intrauterine infections (2-3%)

- *Rubella virus*
- *Cytomegalovirus*
- *Herpes simplex virus*
- *Varicella-Zoster virus*
- *Epstein-Barr virus*
- *Parvovirus B19*,
- *Toxoplasma gondii*
- *Treponema pallidum*

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

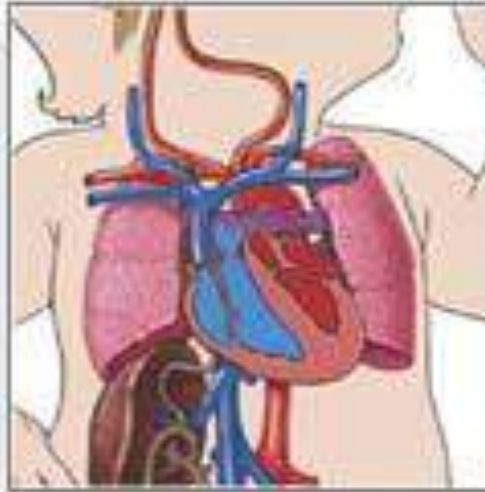

Disease	Birth Defects
Rubella	Cataracts, glaucoma, heart defects, deafness, mental retardation, bone alterations, liver and spleen damage
Cytomegalovirus	Microcephaly, blindness, mental retardation
Herpes simplex	Microphthalmia, microcephaly, retinal dysplasia
Toxoplasmosis	Hydrocephalus, cerebral calcifications, microphthalmia
Syphilis	Mental retardation, deafness, miscarriage, neonatal death, IUGR, stillbirth, premature delivery
Varicella	Cortical atrophy, seizures, chorioretinitis, cataracts, microphthalmia, hypotrophic limbs, hemiatrophy, skin lesions
Parvovirus B -19	Fetal aplastic crisis, intrauterine fetal death

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Rubella Syndrome

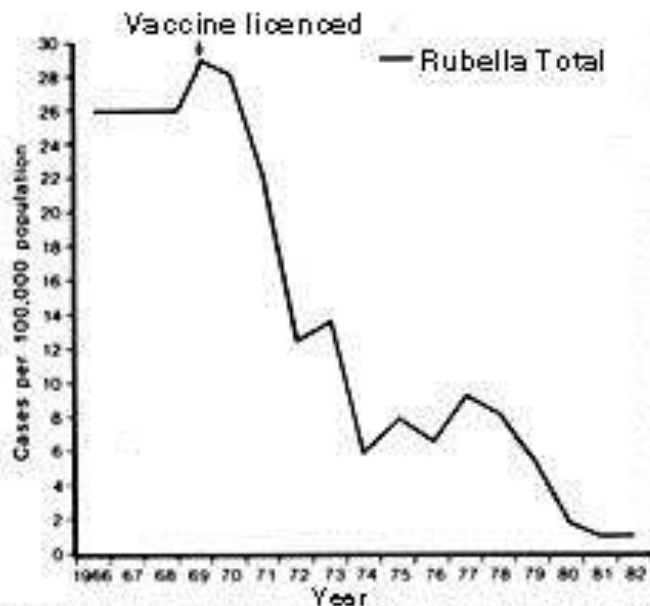

Teratogenicity

In the past, the most common intrauterine infection with a teratogenic agent was rubella. Rubella cases drop after vaccination starts.

Child with congenital rubella syndrome (South 1986).

Decrease in rate of rubella cases in the U.S. between 1966 and 1982. A complementary reduction in congenital rubella syndrome was also observed (South 1986).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Cytomegalovirus is the leading viral cause of congenital abnormalities. 0.2-2% of all infants are infected in utero. 10% of these will develop brain damage.

a) Newborn with CMV infection: note microcephaly. b) Same patient 8 years later with microcephaly, mental retardation and spastic quadriplegia. She is feed through a gastrostomy tube (Reynolds 1986).

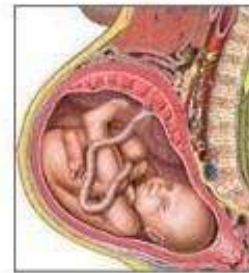

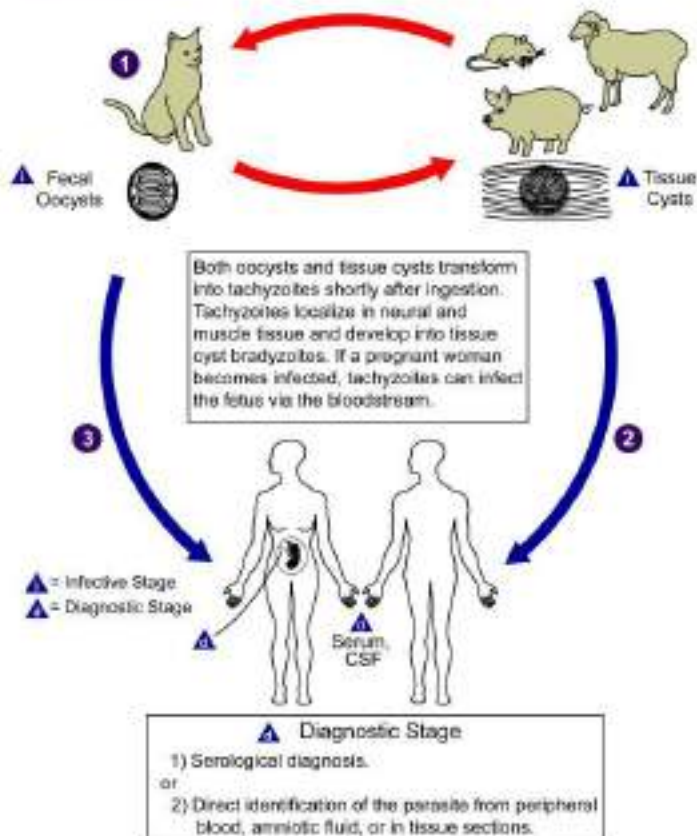

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Toxoplasmosis

(*Toxoplasma gondii*)

A fetus may contract toxoplasmosis through the placental connection with its infected mother

The mother may be infected by:

Improper handling of cat litter

Handling or ingesting contaminated meat

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

II. Anomalies caused by environmental factors (3-9%)

2. Maternal metabolic disorders (1-2%)

- Diabetes mellitus (congenital heart disease, renal, gastrointestinal, and central nervous system malformations)
- Hyperthermia (spina bifida and anencephaly)
- Phenylketonuria (mental retardation, low birth weight, and congenital heart disease)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

II. Anomalies caused by environmental factors (3-9%)

3. Ionizing radiation (1-2%)

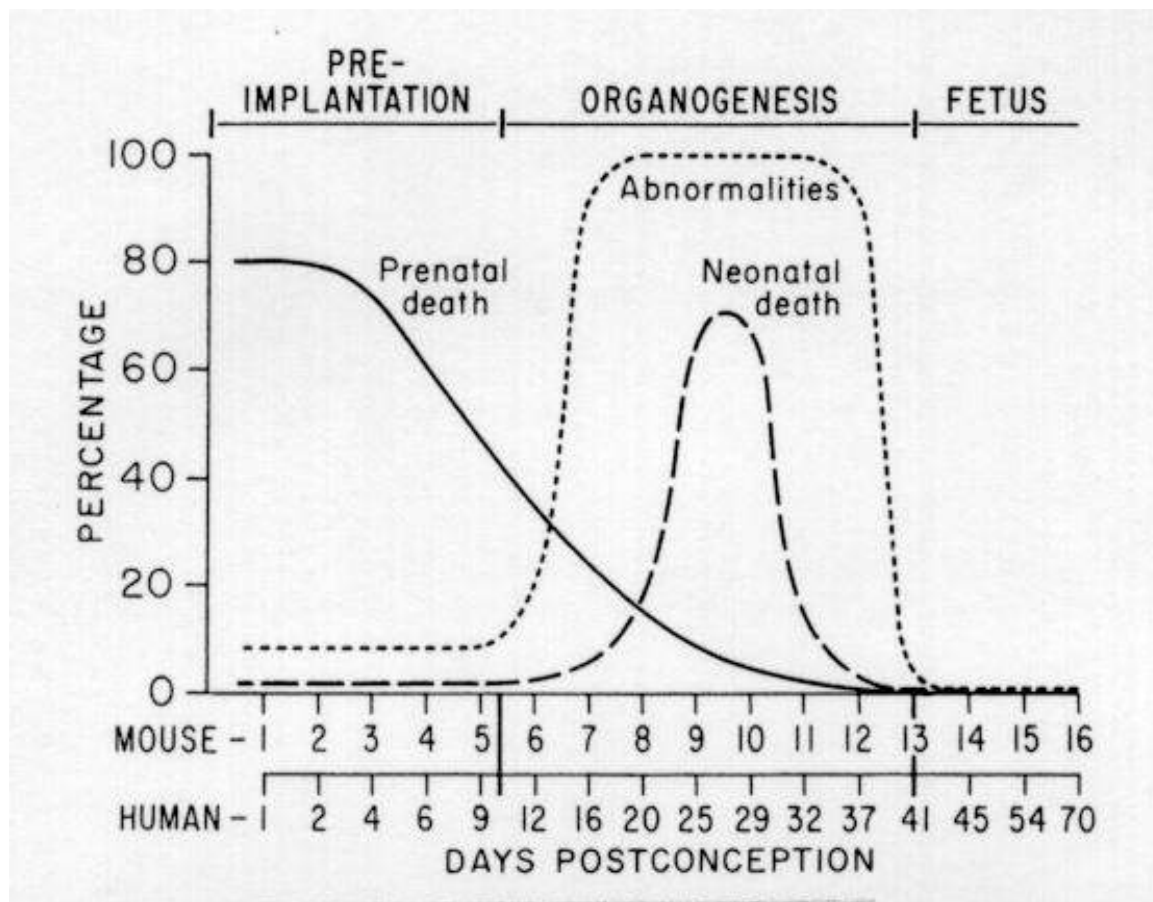

- Growth retardation
- Congenital malformation (microcephaly, microphthalmia, spina bifida, mental retardation, cleft palate..)
- Embryonic, fetal or neonatal death
- Delayed toxic effect (increased incidence of cancer – leukemia)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Embryo is radiosensitive. Embryonic cells have high rates of cell division and cell differentiation.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Effects of Irradiation on the Human Embryo^a

Days after Fertilization	Period of Development	Effects
1-9	Preimplantation	Most probable effect: death, with little chance of malformation
10-12	Implantation	Reduced lethal effects; malformation still unlikely; intrauterine growth retardation (IUGR) predominant effect
13-50	Organogenesis	Production of congenital malformation; retarded growth
51-280	Fetal	Effects on central nervous system; growth retardation with higher doses
All		Increased incidence of cancer and leukemia?

Source: Kirchner (1980), p. 86.

^aBased on mouse and rat studies.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

II. Anomalies caused by environmental factors (3-9%)

4. Drugs (1%)

- Anticonvulsants (Trimethadione, Valproic acid)
- Antimicrobial agents (Tetracycline)
- Anti-cancer chemotherapeutic agents (Cyclophosphamide, Aminopterin, Methotrexate)
- Oestrogens (Diethylstilbestrol)
- Antimalarial agents (Quinine)
- Sedatives (Thalidomide)
- Anticoagulant (Warfarin)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Valproic acid was released in 1967 in Europe and in 1978 in the United States to treat epilepsy.

Approximately 11,500 epileptic women become pregnant each year, many of which use valproic acid.

By 1980, publications began linking malformed children to in utero exposure to valproic acid (greater than 500 mg/day).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

These children were born with lumbosacral spina bifida with menigomyelocele or meningocele, often accompanied by midfacial hypoplasia, deficient orbital ridge, prominent forehead, congenital heart disease and decreased postnatal growth. The proposed mechanism of action is that valproic acid influences folate metabolism, thereby altering the closure of the spinal column resulting in spina bifida.

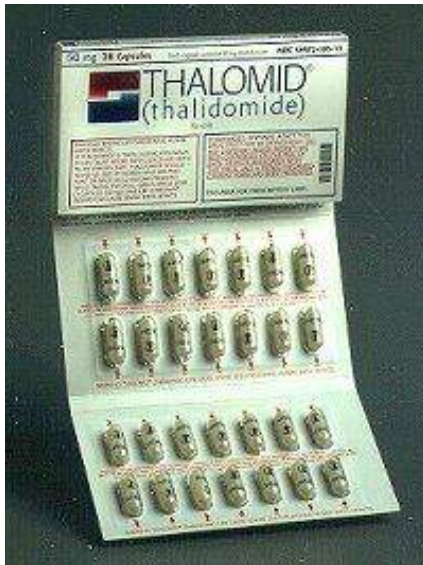

Teratogenicity

On October 1, 1957, Chemie Grünenthal introduced Thalidomide as sedative (sleeping pill).

It became popular as both a sedative and a morning sickness treatment during pregnancy.

3rd best selling drug in Europe.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Unfortunately molecules of the thalidomide chemical crossed the placenta and disrupt the growth patterns of the growing embryo.

10000 to 12000 infants were affected.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Phocomelia

Amelia = absence of limbs

Phokos = seal

Phocomelia = seal limbs

Sketches by Aldrovandus (1642) of a fetus with a phocomelic arm and an epigastric parasite (Wilson 1977).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Warfarin is a synthetic derivative of coumarin, a chemical found naturally in many plants (sweet clover..).
It decreases blood coagulation by interfering with vitamin K metabolism.
Inhibits biosynthesis of vitamin K-dependent zymogens

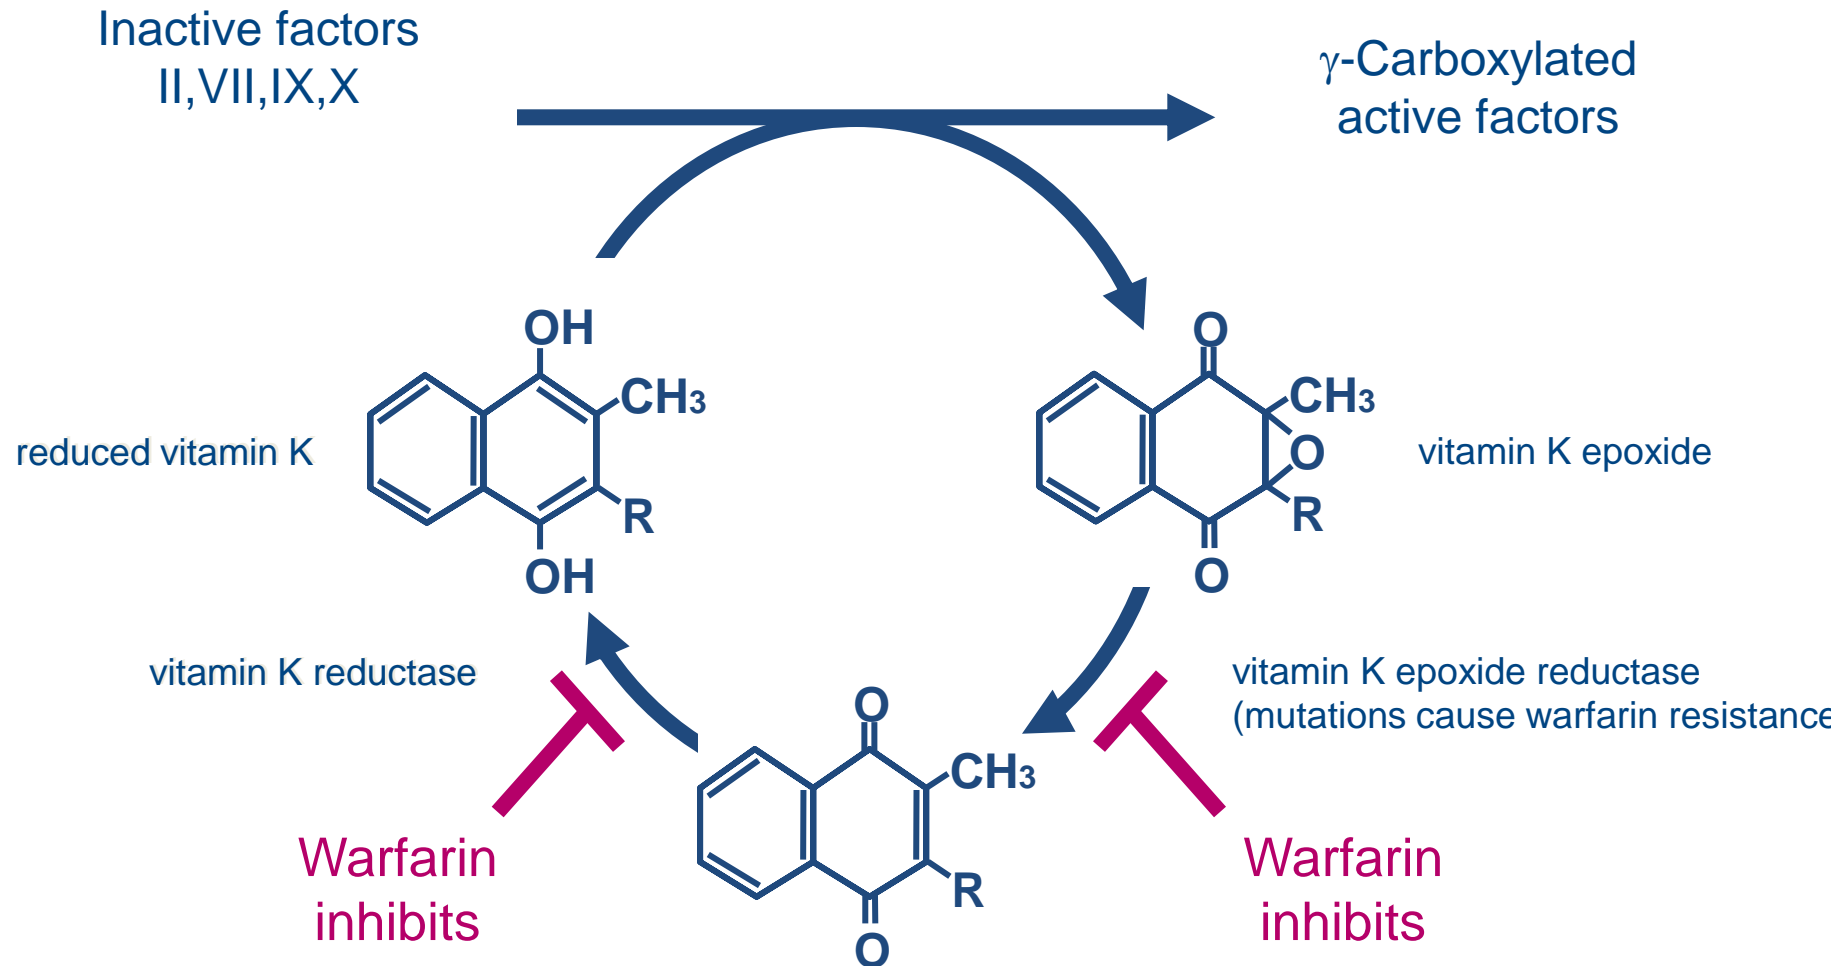

Yellow Sweet Clover
(*Melilotus officinalis*)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Vitamin K cycle

Teratogenicity

Warfarin is used to prevent thrombosis (clots) and embolism in many disorders.

It was initially marketed as a pesticide against rats and mice and is still popular for this purpose. A few years after its introduction, warfarin was found to be effective and relatively safe for preventing thrombosis and embolism in many disorders.

It was approved for use as a medication in the early 1950s and has remained popular ever since.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Fetal Warfarin Syndrome: infant with hypoplastic nose, flat face and low nasal bridge as well as altered calcification (Smith 1982).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

II. Anomalies caused by environmental factors (3-9%)

5. Environmental chemicals (4%)

- Dioxin
- Heavy metals: Pb, Cd, Hg
- Abusus drugs: cocaine, heroine

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Teratogenicity

Fetal Minamata Disease

In 1955 in the Minamata Bay area of Kyushu, Japan, there was a large influx of cases of severe neurological disorders in newborn children. Some villages had 6-12% of their newborns affected.

In 1959, it was found that mercury was being dumped into the bay by a plant of the Chisso Corporation.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Befektetés a jövőbe
Új Magyarország
FEJLESZTÉSI TERV

Teratogenicity

Inorganic mercury from Chisso plant discharge into downstream bay, converted by bacteria into methyl mercury.

It is concentrated in the flesh of fish.

Teratogenicity

Children with Congenital Minamata Syndrome seem to be normal at birth and begin to present symptoms at approximately six months of age. They have instability of the neck, convulsions, reduced IQ, microcephaly, malformed limbs, restricted growth and an altered cerebellum. In utero exposure to methyl mercury induces general brain atrophy and hypoplasia.

Children with Congenital Minamata Disease due to intrauterine methylmercury poisoning (Harada 1986).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

III. Anomalies caused by multifactorial or unknown factors (65-75%)

Many birth defects are caused by a combination of genetic and environmental factors. These conditions are said to have multifactorial ("many factors") inheritance.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Fetal Alcohol Syndrome is among the most commonly known causes of mental retardation and is a major public health problem.

Teratogenicity

Historical view of alcohol as a teratogen

„Foolish, drunken, or harebrain women most often bring forth children like unto themselves „

Aristotle in *Problemata*

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

FAS

- Specific pattern of facial features
- Pre- and/or postnatal growth deficiency
- Evidence of central nervous system dysfunction (degeneration)

Brain damage resulting from prenatal alcohol

Mutation

Damage/chemical modification of genetic components (DNA or chromosome) of the cell.

Mutagen

Physical or chemical agent that interacts with DNA to cause a mutation, so the resulting mutation is induced, not naturally occurring and usually at much higher frequency.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Genotoxic agents

1. DNA reactive chemical substances

- base analogues (e.g. 5 bromouracil)
- covalent bonders (alkylating agents, bulky adducts)
- oxidative chemical agents (free radicals can damage DNA)
- intercalators (e. g. acridine, ethidium bromide, proflavin)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

2. Physical mutagens

High-energy ionizing radiation: x-rays and g-rays → strand breaks and base/sugar destruction (cause extensive chemical alterations).

Nonionizing radiation: UV light → thymine dimers from adjacent.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Types of mutagens

- ♦ **Primer**

- ⇒ act directly (parent molecule)
(alkylating agents)

- ♦ **Secundaer**

- ⇒ become mutagens after metabolism
(benzpirene, nitrosamines)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Mutagenicity

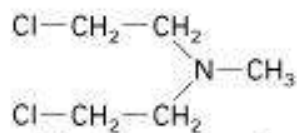

DIRECT-ACTING CARCINOGENS

Ethylmethane sulfonate (EMS)

Dimethyl sulfate (DMS)

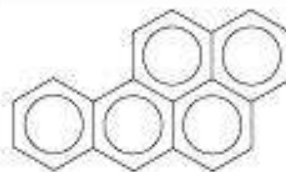

Nitrogen mustard

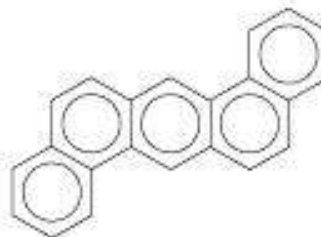

Methyl nitrosourea (MNU)

INDIRECT-ACTING CARCINOGENS

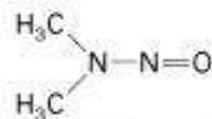

**Benzo(a)pyrene
(3,4-benzpyrene)**

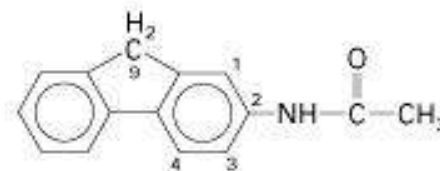

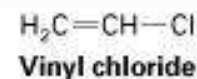

Dibenz(a,h)anthracene

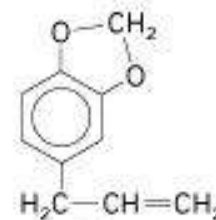

2-Naphthylamine

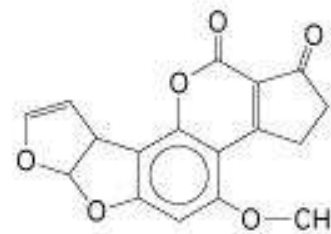

Dimethylnitrosamine

2-Acetylaminofluorene

**Safrole
(sassafras)**

**Aflatoxin B₁
(Aspergillus flavus)**

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Types of mutation

♦ Gametic

- ⇒ occur in germ cells
 - ⇒ realise in offspring (somatic + germ cell)
 - ⇒ lead to birth effect
- ⇒ spread in the population

♦ Somatic

- ⇒ occur in somatic cells
 - ⇒ realise within the body
 - forming cancer
- ⇒ discontinue with death

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Types of mutation

Spontaneous mutations

Happen naturally, not as a result of any specific agent(s).

Replication errors or base modification as a result of chemicals (endogenous) naturally present in the cell (oxygen, acids, etc.).

Induced mutations

Mutations that result from the influence of an extraneous factor. X-rays, UV light, chemicals not of cellular origin.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Types of mutation

Classification based on phenotypic effects

Loss of function mutation

Eliminates the function of the gene product.
Also called null mutations or gene knockouts.

Gain of function mutation

Give gene product a new function.
Generally a dominant allele.
Can give a protein a new function or cause a regulatory effect to express old protein at new time or under new conditions.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Types of mutation

Classification based on phenotypic effects

Nutritional or biochemical effect

Microbial auxotrophs.

Behavioral mutation

Mating behavior or circadian rhythms.

Regulatory mutation

E. coli lac operon operator/promoter region.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Types of mutation

Classification based on phenotypic effects

Lethal mutation

Loss of essential function.

Conditional mutation

Temperature sensitive mutations.

Neutral mutations

Commonly occur in non-gene portion of genome and have no effect on gene product/function, not selected for or against.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

POINT MUTATION

I. A single base change

1. Transition

Purine or pyrimidine is replaced by the other.

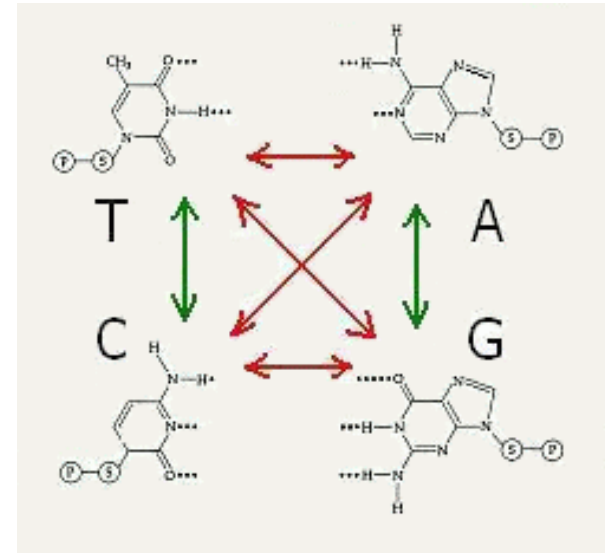

$A \leftrightarrow G$; $T \leftrightarrow C$

2. Transversion

A purine is replaced by a pyrimidine or vice verse.

$A \leftrightarrow T$ or C $T \leftrightarrow A$ or G

$G \leftrightarrow T$ or C $C \leftrightarrow A$ or G

Effects of a point mutation

The sites

- Noncoding DNA
- Nonregulatory DNA
- 3rd position of a codon

Types

Silent mutation

Phenotypic effects

No

Coding DNA → altered AA

Missense mutation

Yes or No

Coding DNA → stop codon
→ truncated protein

Nonsense mutation

Yes

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

POINT MUTATION

II. Frameshift mutation

1. Insertion

The addition one or more bases in a DNA region.

2. Deletion

The loss of one or more bases in a DNA region.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

CHROMOSOMAL ABERRATIONS

2. Numerical aberrations

⇒ (euploid – $2n$) set multiplication
⇒ poliploidy ($3n, 4n, \dots$)

⇒ aneuploidy
euploid set $\uparrow \downarrow$ with few chromosome

nullisomy ($2n-2$) monosomy ($2n-1$)

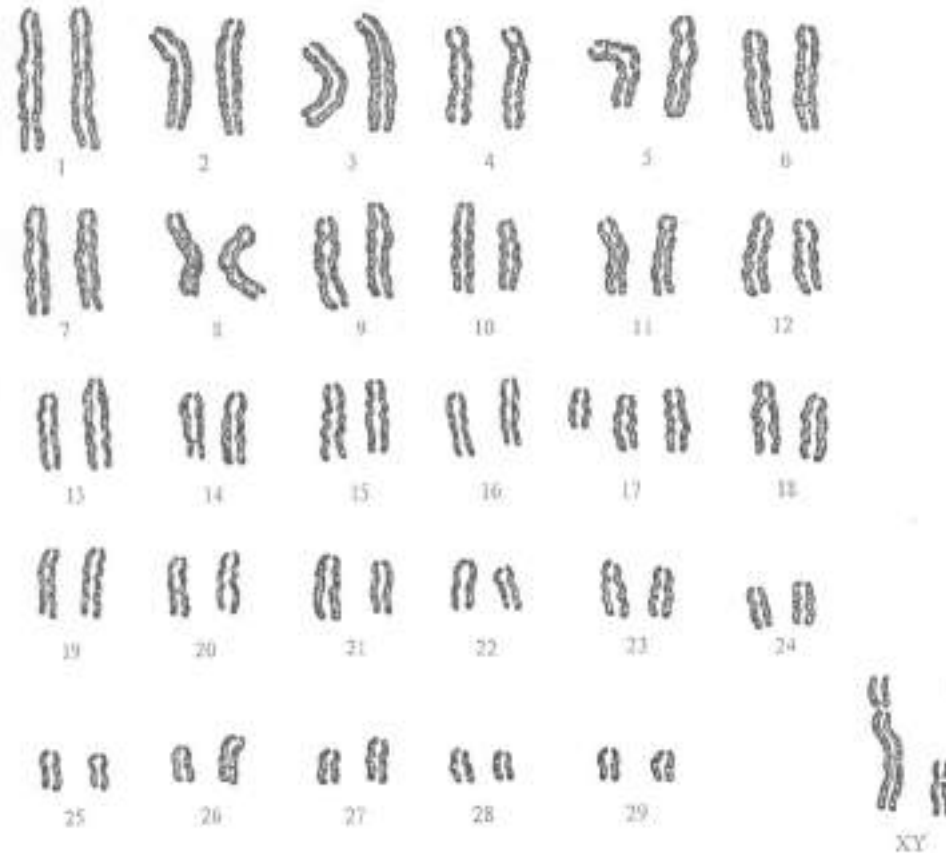

trisomy ($2n+1$) tetrasomy ($2n+2$)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Numerical chromosomal aberration (trisomy $2n+1$)

MUTAGENESIS

It is the molecular process in which the mutation is generated, including direct and indirect mutagenesis.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

MECHANIM OF ACTION

DIRECT (reactive agents directly react with DNA)

- ♦ alkylating
- ♦ deamination
- ♦ base analogs
- ♦ hydroxylation of base
- ♦ tautomeric shifts
- ♦ bulky adducts
- ♦ intercalations
- ♦ breaking of DNA (X-rays, radioactive radiation)
- ♦ thymine dimer formation

INDIRECT (damage indirectly by different mechanism)

- ♦ damaging of cell defense against superoxide radicals
- ♦ peroxisome proliferators
- ♦ modification of protein/nucleic acid synthesis (base analogs)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Direct mutagenesis

1. Alkylating

Alkylating agents are electrophilic chemicals which readily add alkyl (e.g. methyl) groups to various positions on nucleic acids.

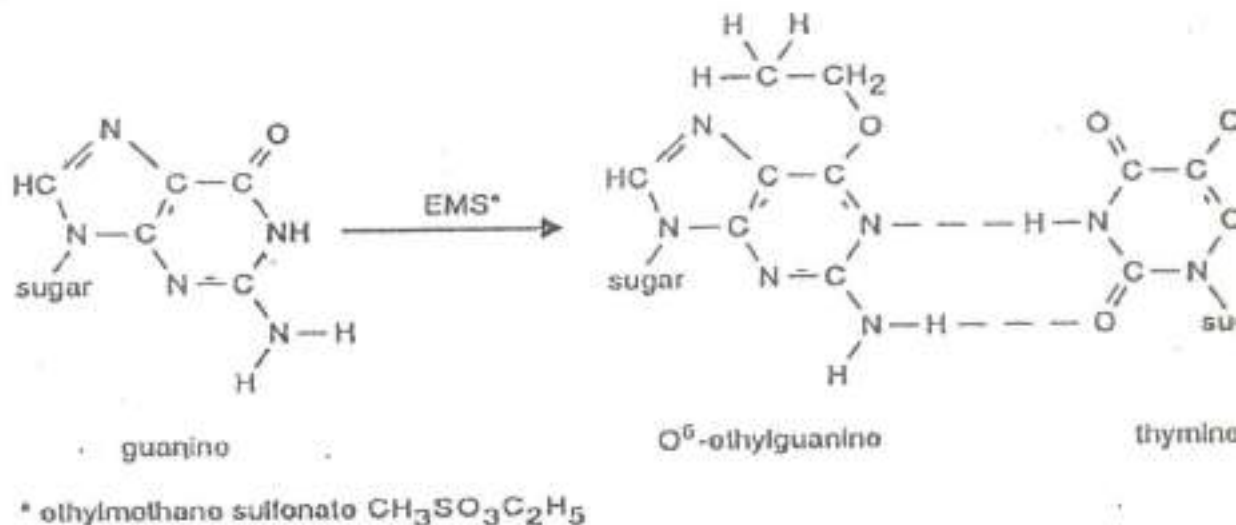

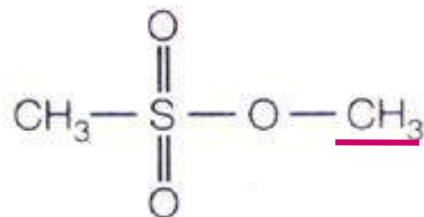

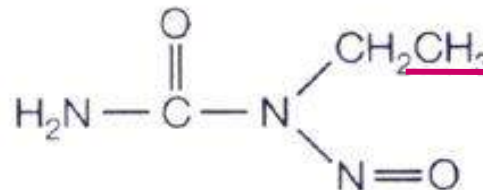

FIGURE 11.8
Binding of an ethyl group originating from EMS to guanine

Mutagenicity

Direct mutagenesis

4. Hydroxylation of base

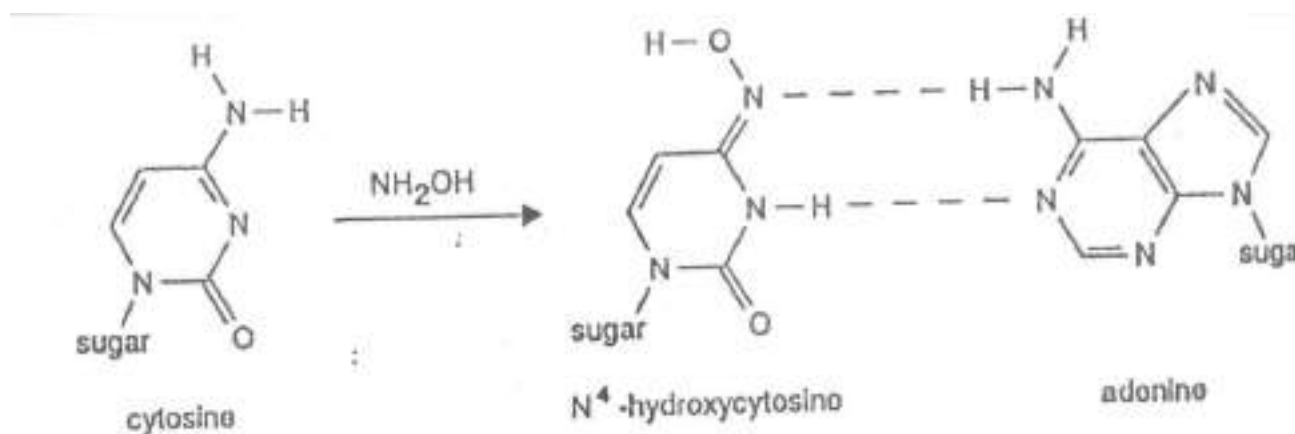

FIGURE 11.6
Chemical modification of a base (cytosine) by hydroxylamine

Direct mutagenesis

5. Tautomeric shifts

All of the bases in DNA can exist in one of several forms, called tautomer, which are isomers that differ in the positions of their atoms and in the bonds between the atoms. The keto form is normally found in DNA. The enol forms of the bases are rare. The complementary base pairing of the enols is different from that of the keto forms (e.g. hidroxilamin).

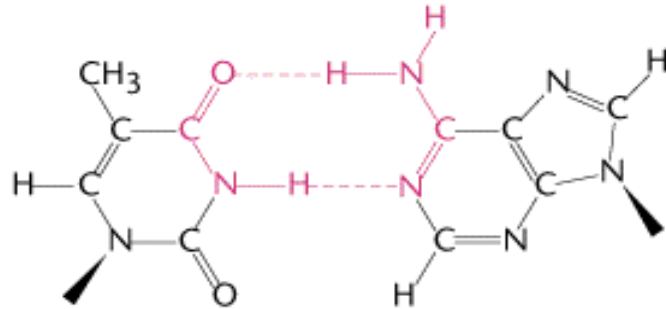

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

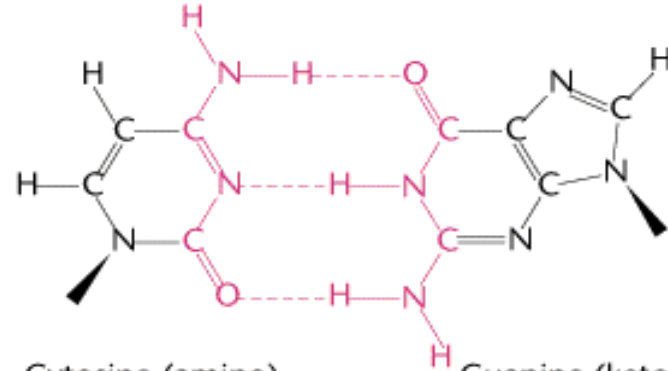

Mispairing due to tautomeric shifts

(a) Standard base-pairing arrangements

Thymine (keto)

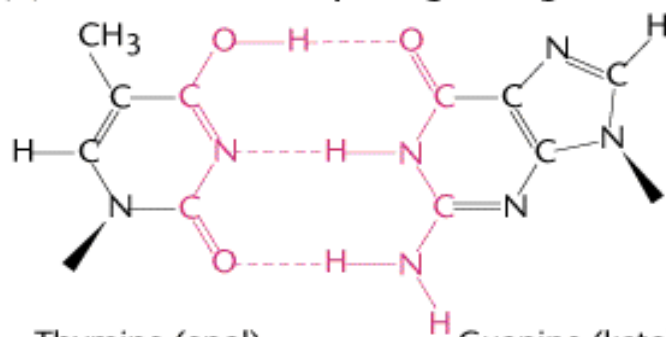

Adenine (amino)

Cytosine (amino)

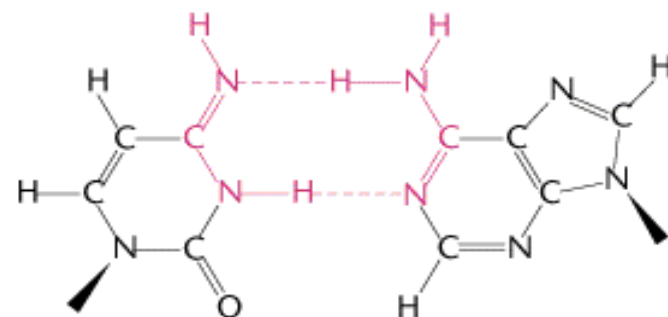

Guanine (keto)

(b) Anomalous base-pairing arrangements

Thymine (enol)

Guanine (keto)

Cytosine (imino)

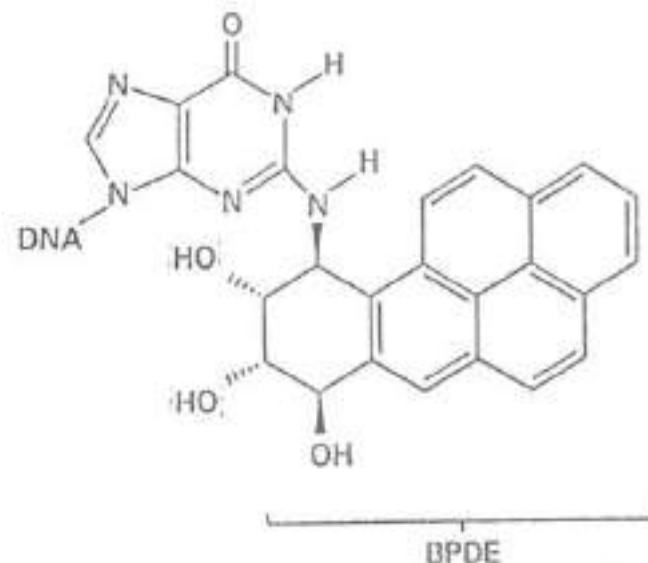

Adenine (amino)

Direct mutagenesis

6. Bulky adducts

e.g. PAH (covalent adduct)

A kind of DNA lesions that distort the double helix and cause localized denaturation. These lesions disrupt the normal function of the DNA.

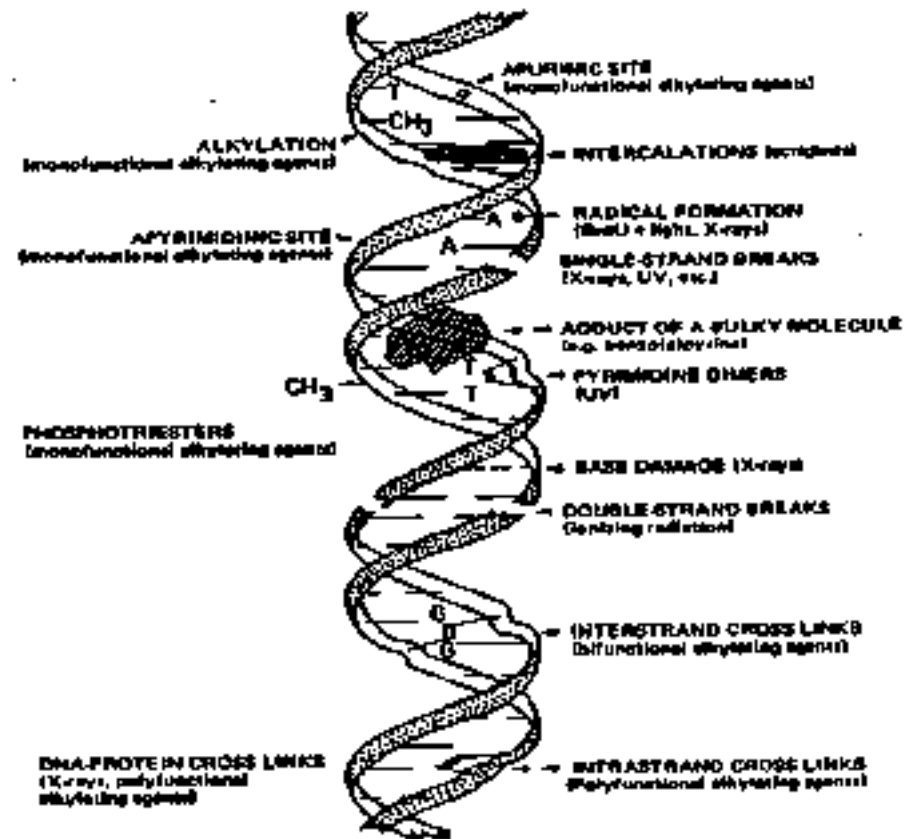

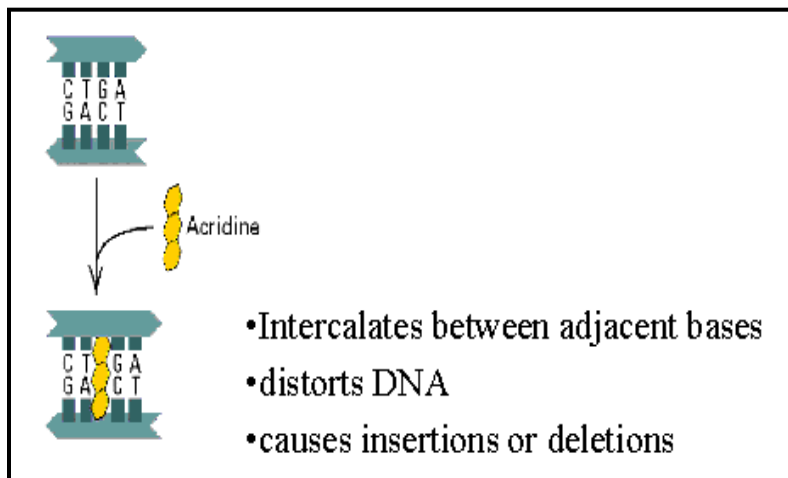

Direct mutagenesis

7. Intercalations

e.g. acridines

8. Strand breaks

e.g. ionizing radiation

Direct mutagenesis

9. Thymine dimer formation

e.g. UV radiation (260 nanometer wavelength)

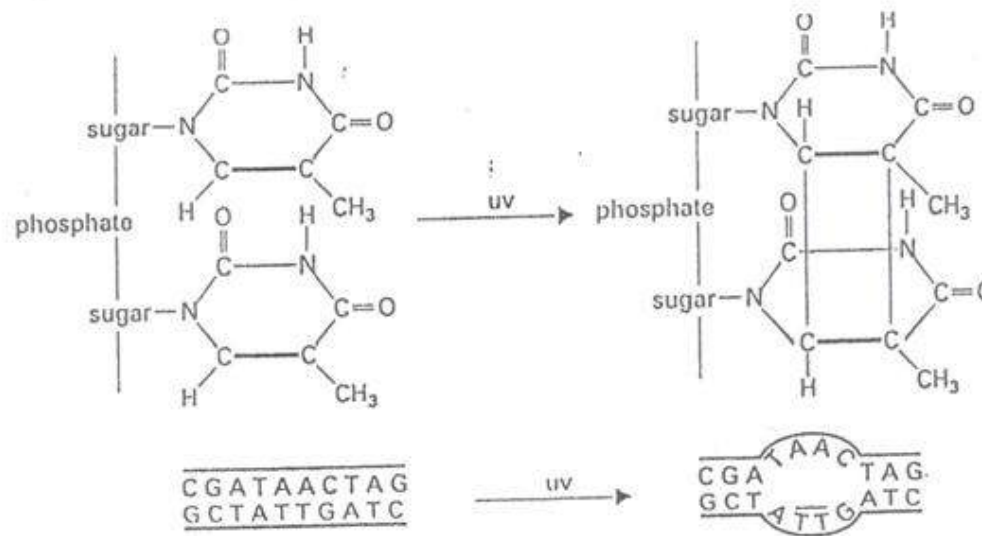

FIGURE 11.19
Structure of a thymidine dimer (upper part) and disturbance of the DNA helix (lower part) as a result of the presence of a dimer

Indirect mutagenesis

1. Damaging of cell defense against superoxide radicals

- inhibition of superoxide dismutase (e.g. dithiocarbamate fungicides)

2. Peroxisome proliferators

- peroxisome→lipid metabolism→free radicals→DNA damage (e.g. chlorophenoxy-acetic-acid herbicides)

3. Modification of protein/nucleic acid synthesis

- inhibition of ribonucleotide reductase e.g. hydroxyurea
- thymine (+)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Consequences of mutagenesis

- ♦ Numerical changes

 - ⇒ intrauterine death

- ♦ Structural changes

 - ⇒ depend on part of chromosome
 - reduced function
 - function loss
 - appearance of a new property

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Consequences of mutagenesis

DNA REPAIR MECHANISMS

DNA repair mechanisms can be classified into different categories based on the way of operation.

- Direct correction or direct reversal- reversing the damage.
- Excise the damaged areas and then repair the gap by new DNA synthesis.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

DNA repair mechanisms

I. Repairing of DNA damage before replication

1. Direct correction

a. Photoreactivation repair

Photolyase enzyme can split thymidine dimers: breaks the covalent bond.

b. Alkyltransferases

Alkylation is repaired by enzymatic transfer of methyl group by Methyl Guanine-DNA MethylTransferase.

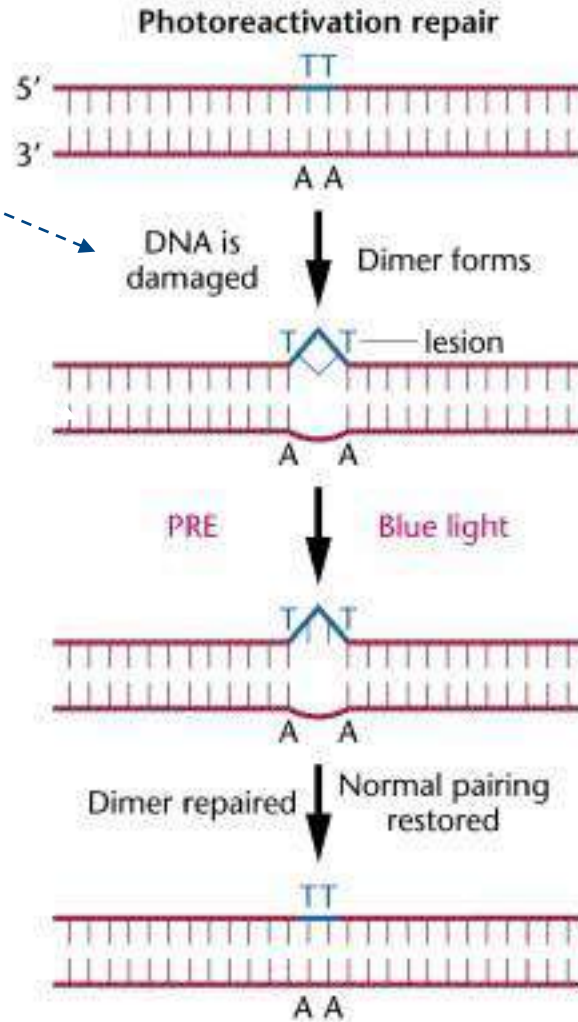

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Mutagenicity

UV

Photoreactivation
Enzyme Cleaves

Visible light

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

I. Repairing of DNA damage before replication

1. Direct correction

c. N-glycosylase

Hypoxanthine product of adenine deamination is recognized, removed by hypoxanthine N-glycosylase then replaced by adenine.

d. Ligase

Simple breaks (by ionizing radiation) in one strand are repaired by DNA ligase. DNA ligase joins the DNA segments.

e. Cyclase

Close the opened ring (ring opens by ionizing radiation).

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

2. Excise the damaged areas and then repair the gap by new DNA synthesis

a. Base excision repair

Repair glycosylase enzyme recognizes the damaged base and removes it, the baseless-sugar is then excised, the gap is filled by a repair DNA pol and ligase.

b. Nucleotide excision repair

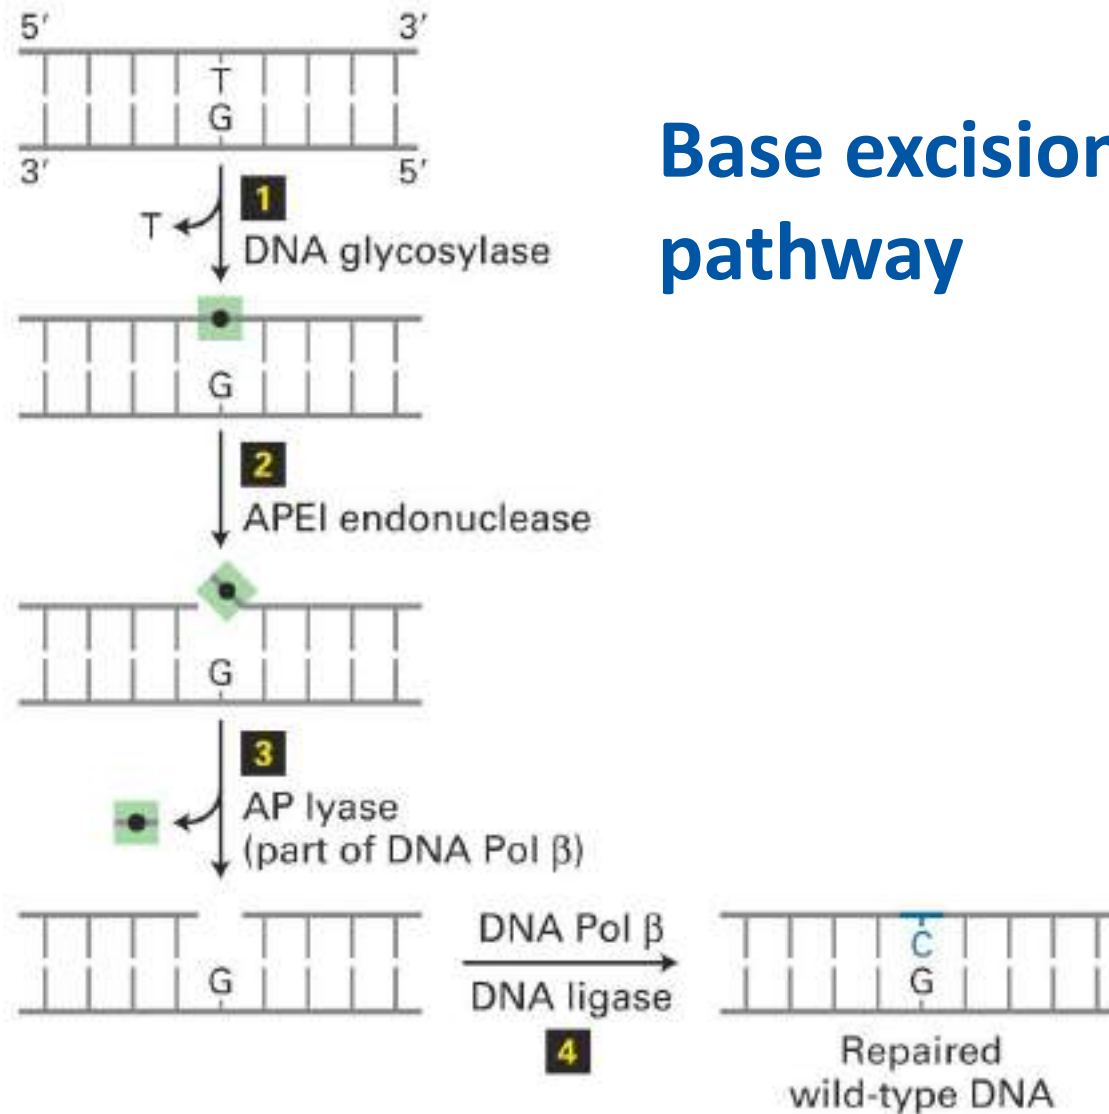

Excision Repair (dark repair or nucleotide excision repair – NER)-not photoactivated, repairs thymidine dimers and other distortions in the DNA.

TÁMOP-4.1.2.A/2-10/1-2010-0012

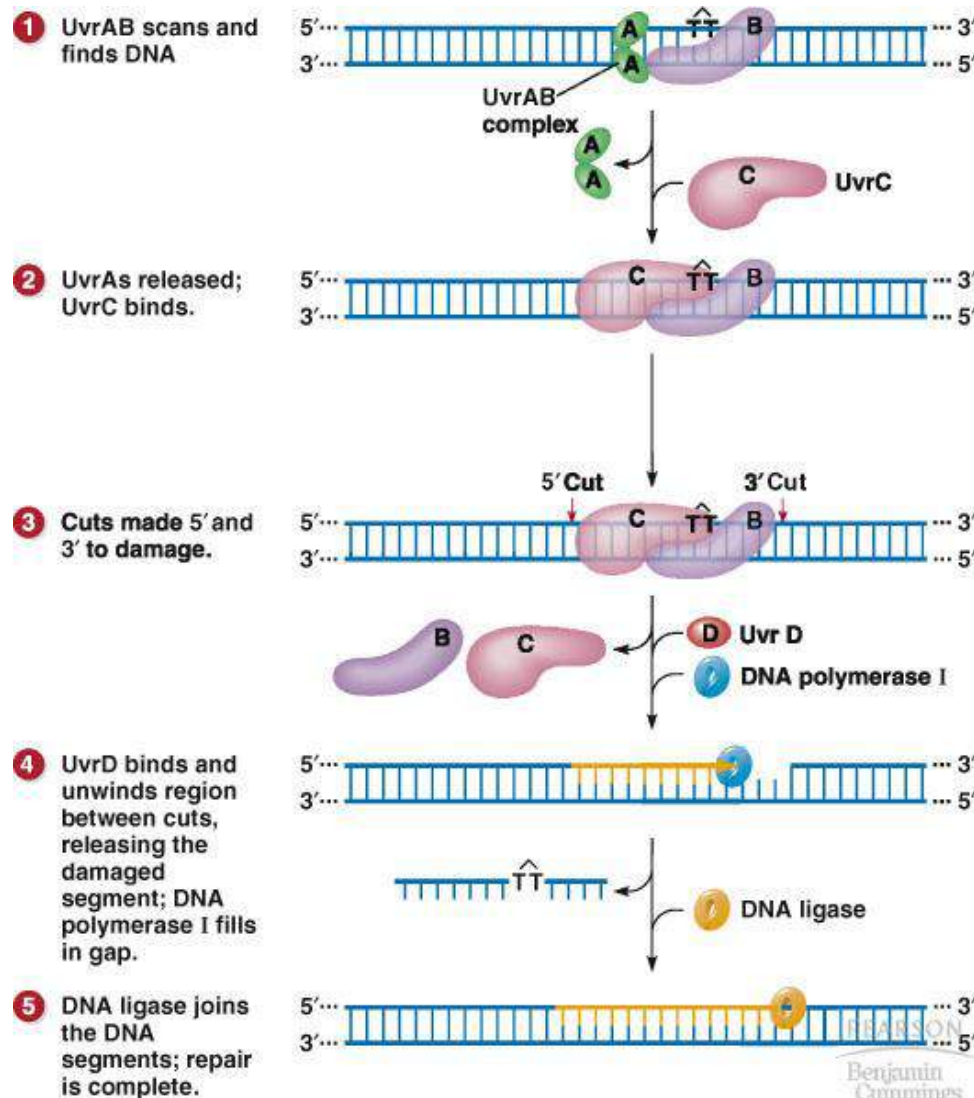

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Base excision repair pathway

Mutagenicity

Nucleotide excision
repair (NER) of
thymidine dimer
and other damage
induced distortions
of DNA.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

II. Repairing of DNA damage during replication

1. Bypass repair

e.g. SOS repair

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

SOS repair

Level of DNA damage exceeds ability of normal repair systems to rapidly correct.

RecA cleaves LexA and the SOS induction occurs (also induces any prophage).

“Method of last resort”.

Involves “error-prone” DNA synthesis as site of mutation.

Generally used to fill in gaps opposite lesions over which a replication fork has passed.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

III. Repairing of DNA damage after replication

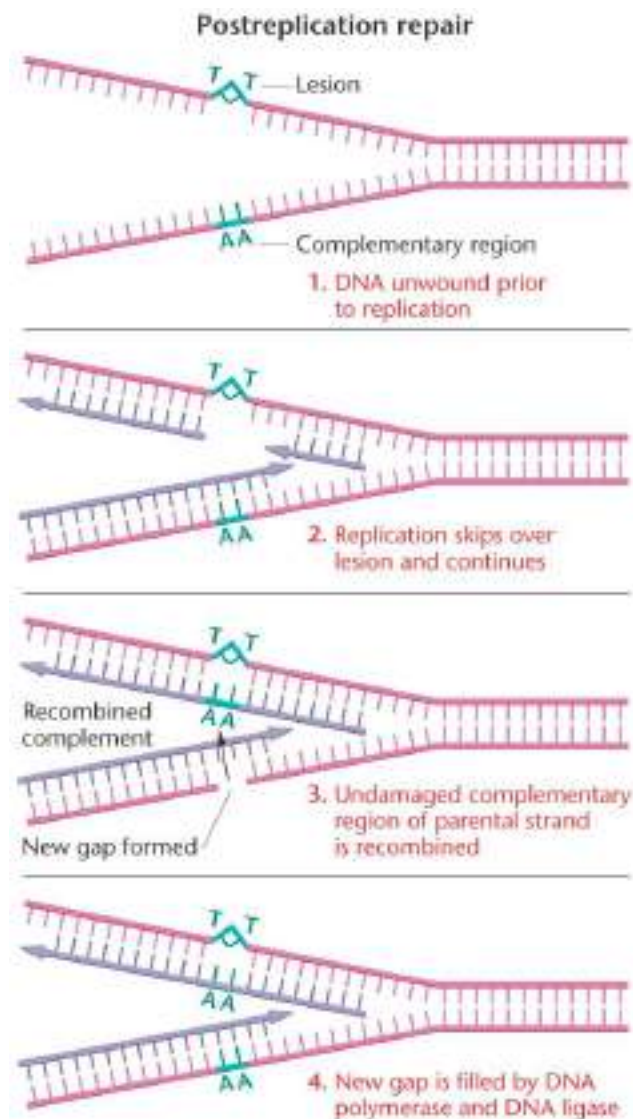

1. Recombination repair
2. Copy choice repair
3. Gap filling repair

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Mutagenicity

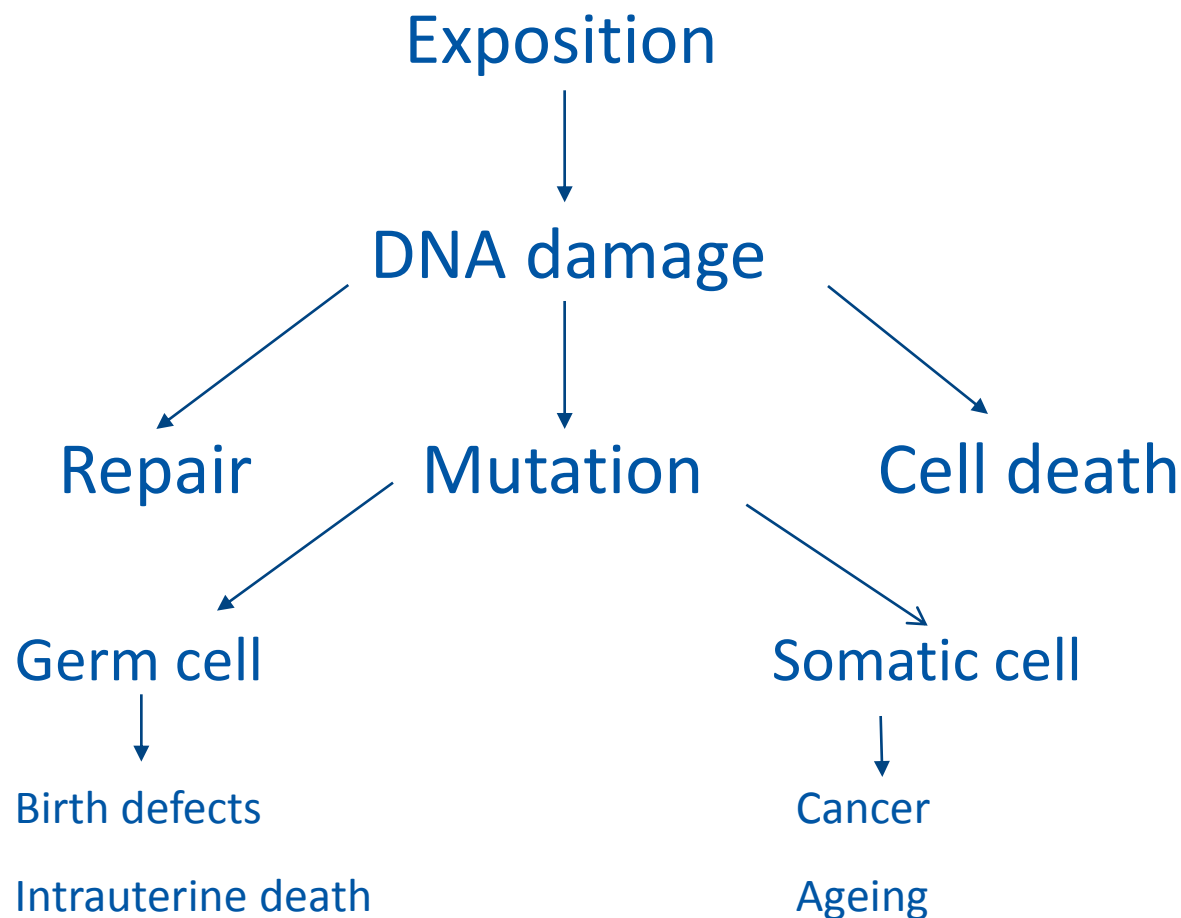

Copyright © 2006 Pearson Prentice Hall, Inc.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Final consequences of genotoxic effect

Neoplasia – „new growth”

Neoplasia

It is an abnormality of cell growth.

Cancer – „crab”

Carcinogen

A carcinogen is an agent that can cause cancer or shorten the process of tumor development.

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

THEORY

One-stage process

- moment-like change of one DNA
- Cohnheim – disconnection
- Virchow – irritation

Multi-stage process

- result of more changes
- mutation of oncogen
- damaging of suppressor (inhibitor) gene

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Oncogenes

Oncogenes are cellular genes that normally stimulates cell growth and proliferation.

An oncogene is a gene that when mutated or expressed at abnormally-high levels contributes to converting a normal cell into a cancer cell.

Tumor suppressor genes

Tumor suppressor genes are cellular genes that normally suppress cell growth and proliferation.

If tumor suppressor genes were mutated or inactivated it will lead to cell transformation → cancer

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogenicity

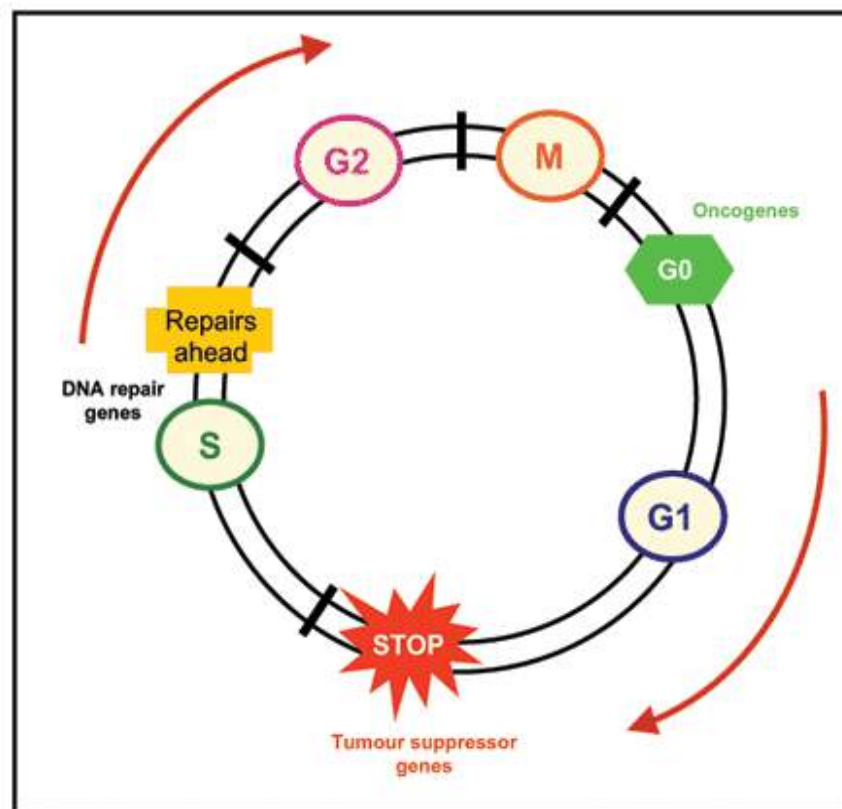

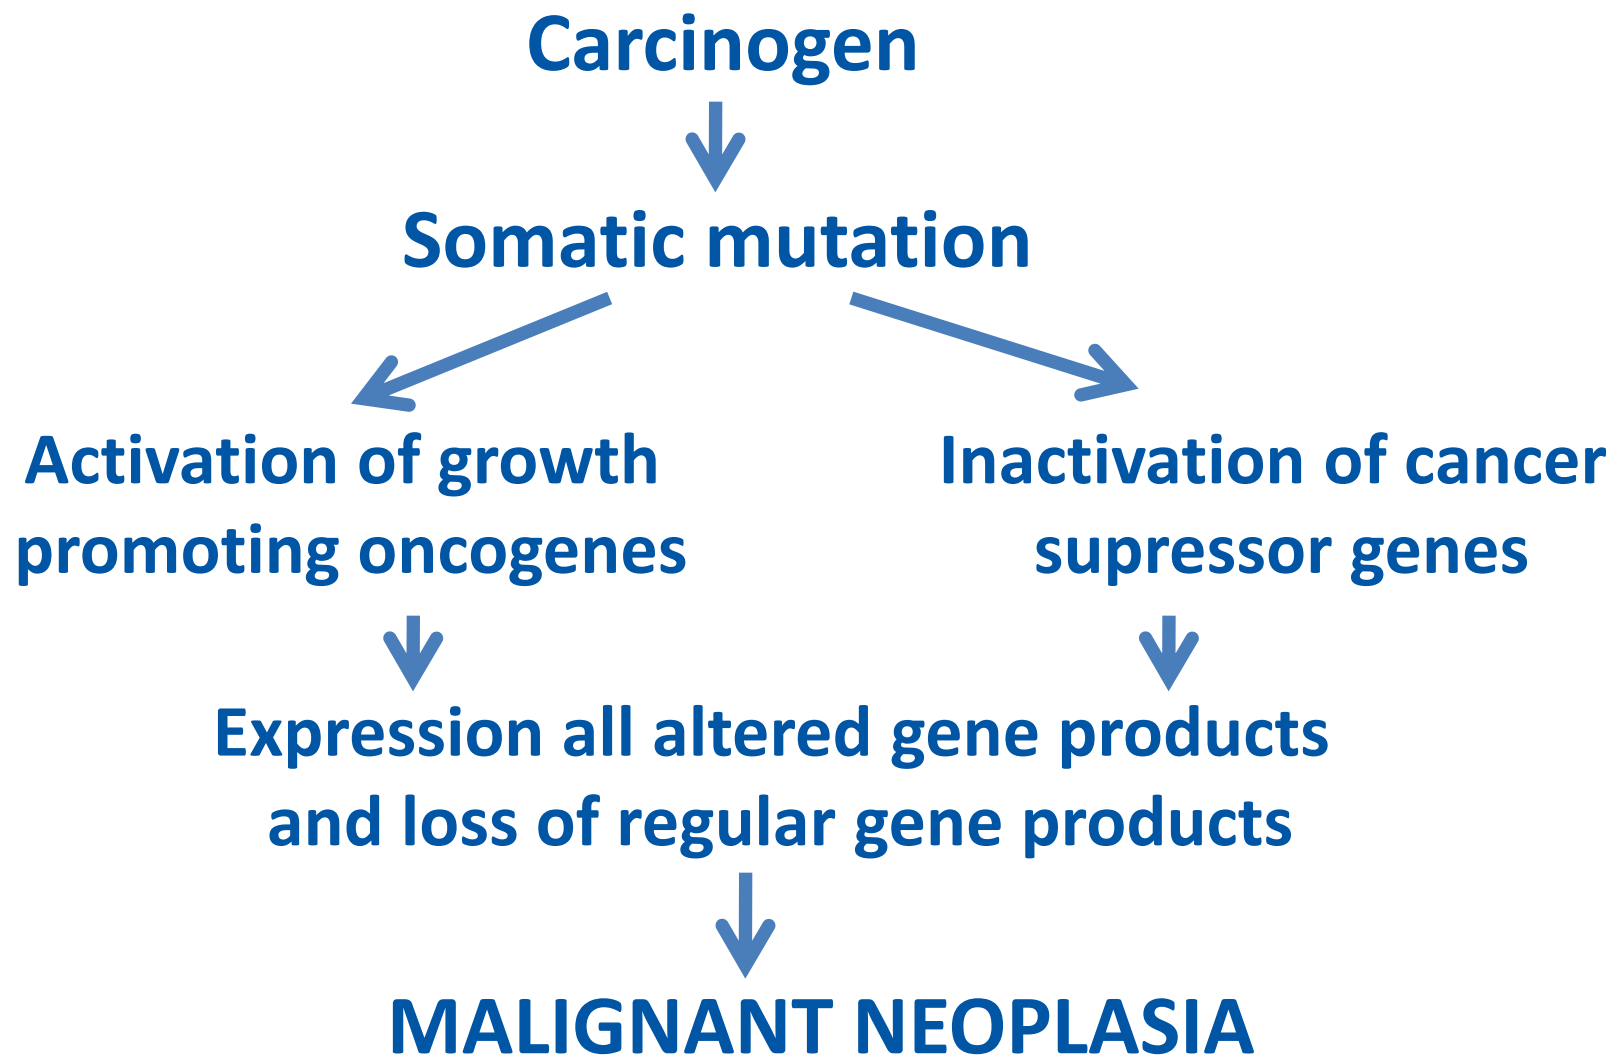

Fig. 6 – Cell cycle and its control by molecular targets (oncogenes and tumour suppressor genes). The cell cycle is a critical process that a cell undergoes in order to copy itself exactly. Most cancers cause mutations in the signals that regulate a cell's cycle of growth and division, namely in oncogenes (which act as dominant mutations) and tumour suppressor genes (that function recessively). Normal cell division is required for the generation of new cells during development and for the replacement of old cells as they die. In normal cells, tumour suppressor genes act as braking signals during G1 to stop or slow the cell cycle before it reaches the S phase. DNA repair genes are active throughout the cell cycle, particularly during G2 after DNA replication and before the chromosomes prepare for mitosis.

Phases of mechanism

Initiation

- binding covalently to DNA (adducts)
- change in the genetic material of the cell
- stabilization of mutation

Promotion

- changing in cell function
- proliferation of tumor cell
- increasing cancer

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Phases of mechanism

Progression

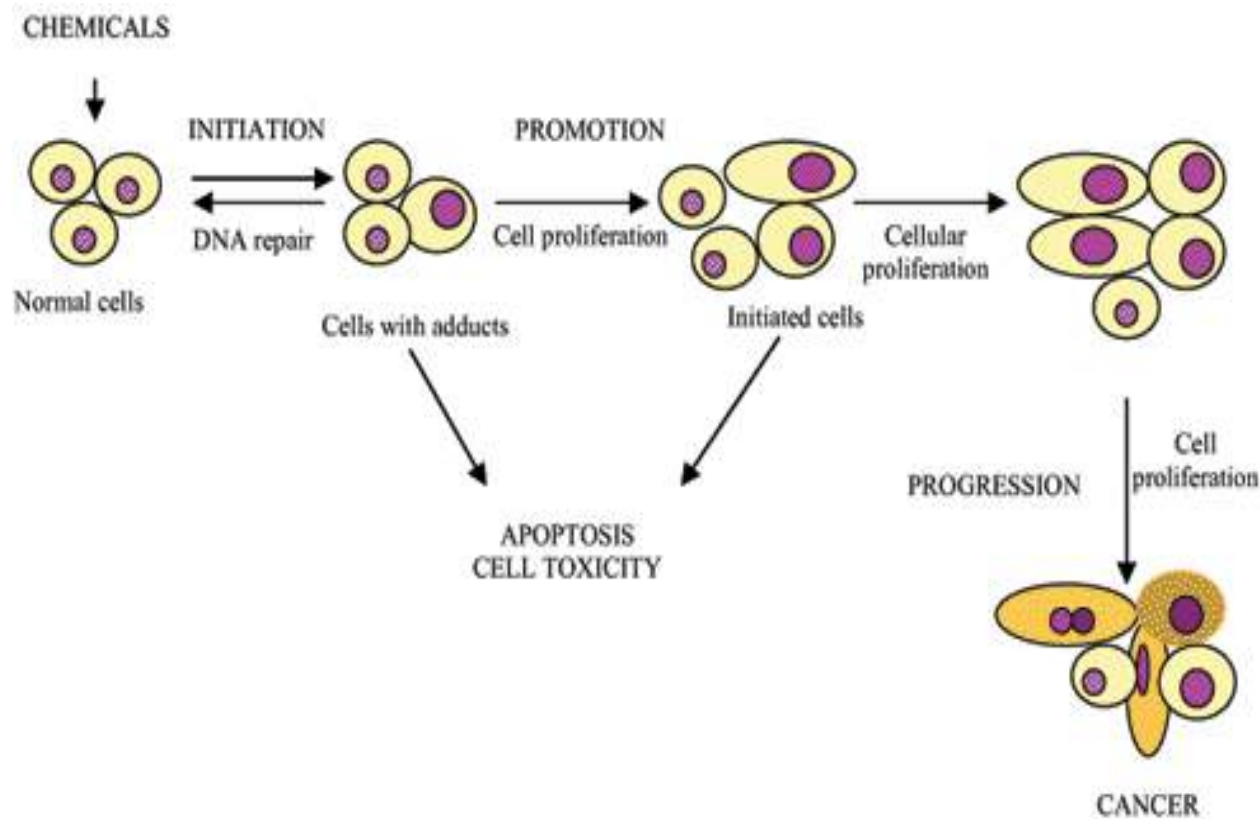

- irreversible tumour
- grow rapidly without restraint
- showing metastases
- become malignant

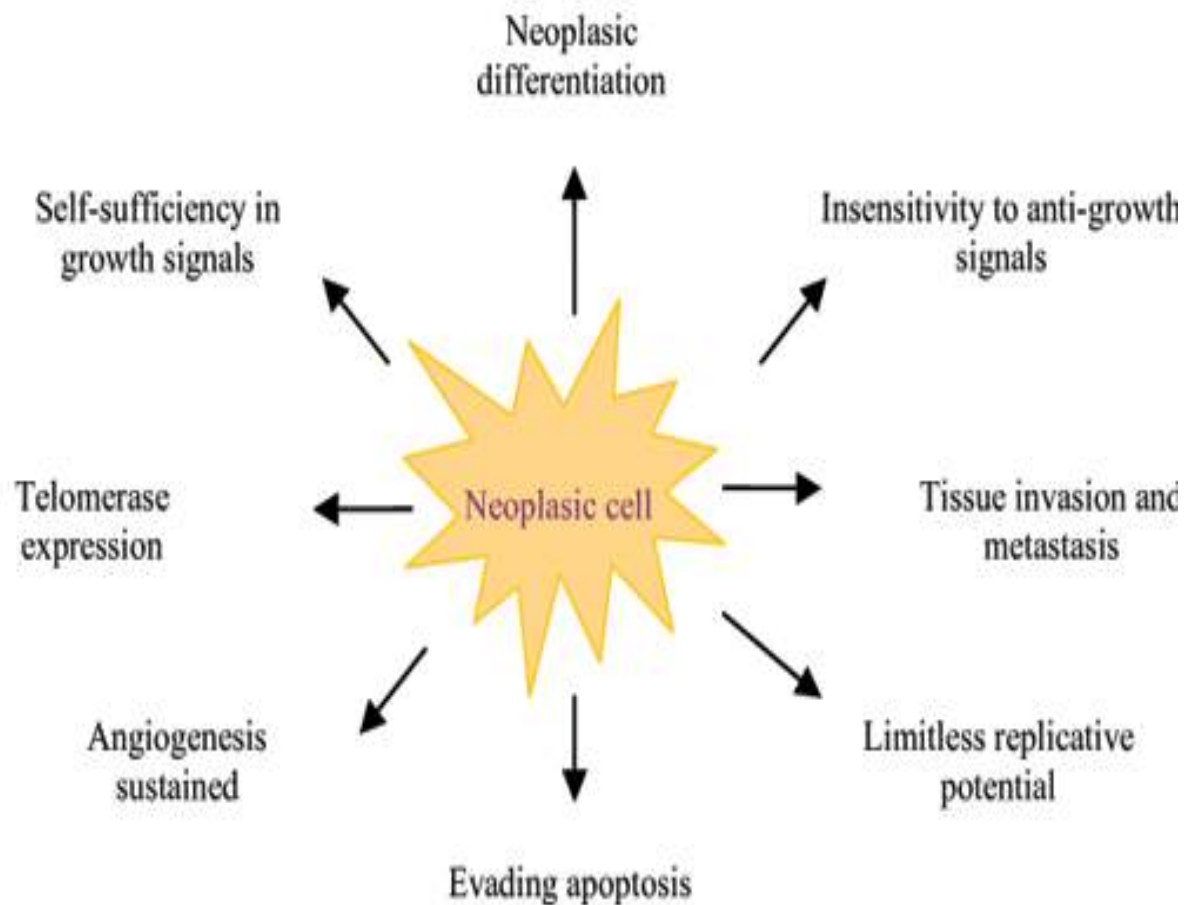

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Phases of mechanism

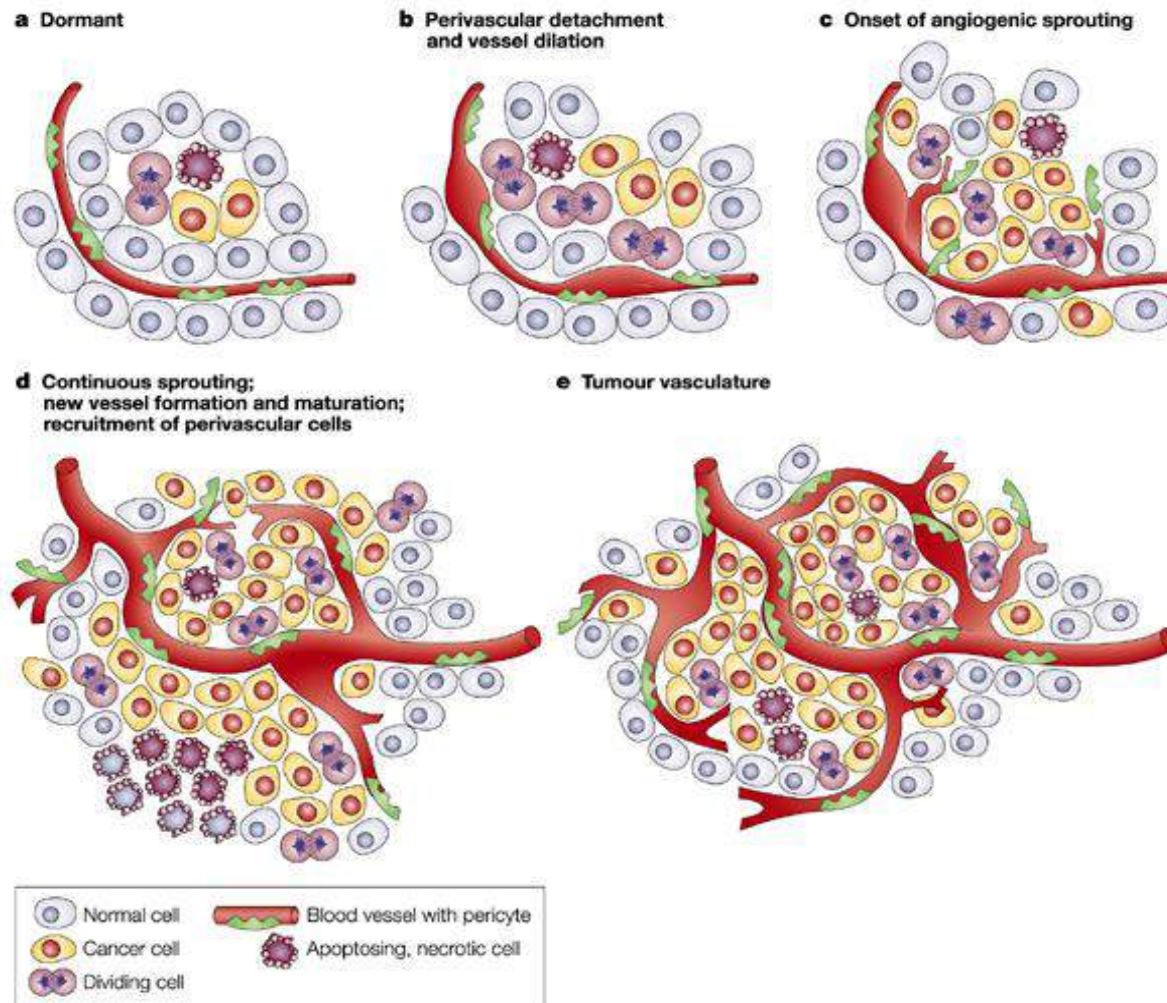

Carcinogenicity

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Angiogenesis

Prognosis

Benign tumour

- slow growth
 - Ø infiltrative, encapsulated
 - Ø form metastases
- ⇒ can usually be removed surgically

Malign tumour

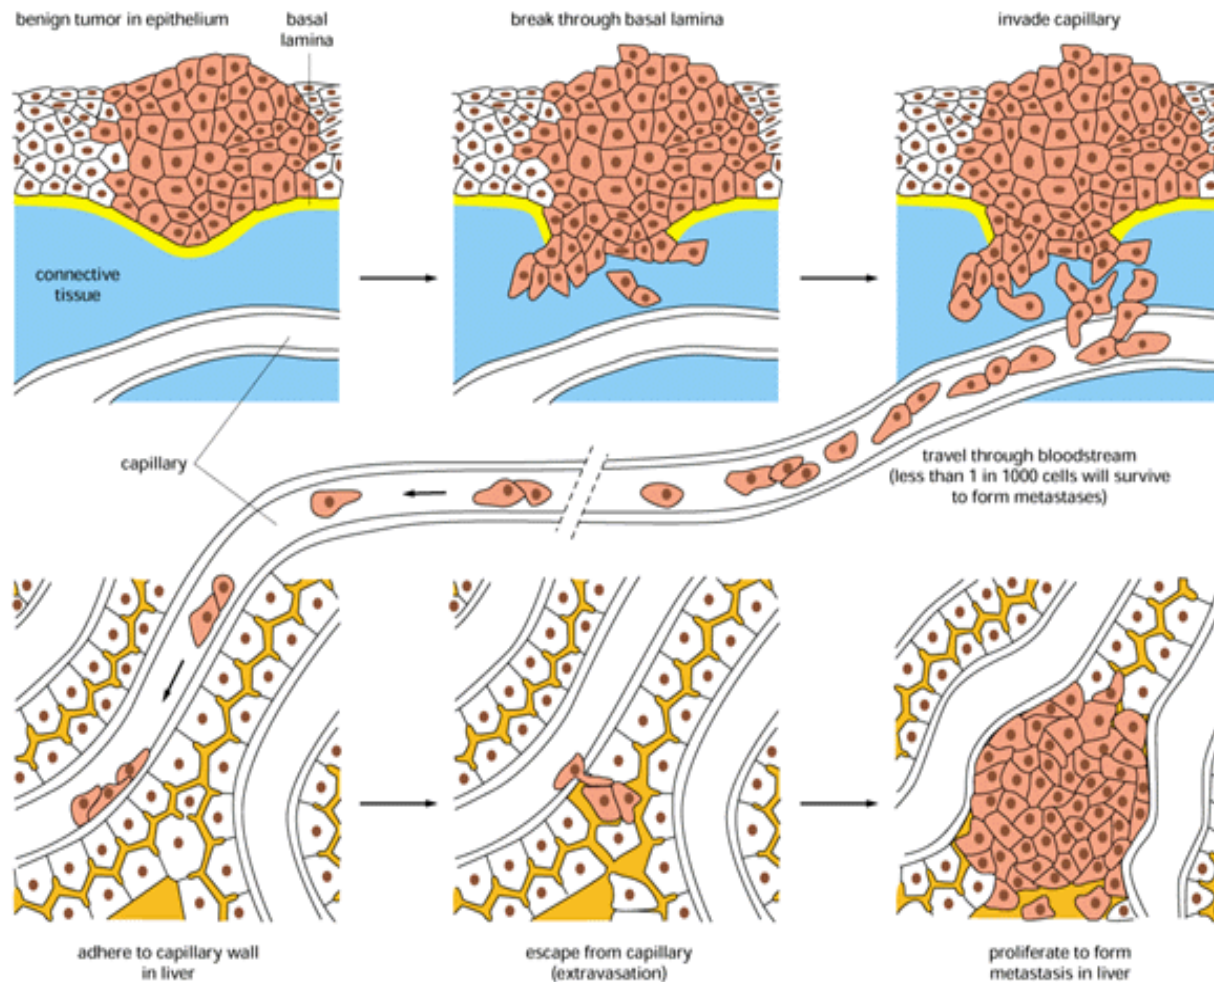

- ability to multiple rapidly
 - invade neighboring tissues
 - forming metastases
- ⇒ difficult to remove surgically

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Metastasis

Type of Carcinogen

Genotoxic carcinogen

Direct biological capacity to damage DNA

- direct-acting – parent molecule (alkylating agent)
- activation-dependent (PAH, nitrosamines)

Properties

- hereditary change
- irreversible effect
- restricted dose-dependent
- \emptyset threshold dose

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogenicity

Type of Carcinogen

Epigenetic carcinogen

Ø direct damage DNA

Operate indirectly by a variety of mechanism

- inhibition of nucleic acid synthesis
- inhibition of mitosis
- immunosuppression

Properties

- reversible effect
- dose-dependent
- threshold dose

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogenic agents

Physical

- ionizing radiation (leukaemia)
- UV radiation (skin)
- asbestos (lungs)

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogenic agents

Chemical

- As, Cd, Ni
- Rd
- PAH
- vinyl chloride
- benzene
- rubber manufacturing
- conversion of timber
- paint manufacturing

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogenicity

TABLE II
Chemical carcinogens.

Group	Compound	Mechanism of action	Affected organs/ Cancer type
Polycyclic aromatic hydrocarbons	Benzo[a]pyrene Polychlorinated biphenyls (Luch 2005)	Form adducts with purine bases of DNA, mainly resulting on transversions	Skin, lungs, stomach Liver skin
Aromatic amines/amides	2-Acetylaminofluorene 4-Aminobiphenyl 2-Naphthylamine (Luch 2005)	Genotoxic compounds, increase the rate of cell duplication	Liver, bladder Bladder Bladder
Aminoazo dyes	o-Aminoazotoluene <i>N, N</i> -dimethyl-4-aminoazobenzene (Golka et al. 2004)	Forms adducts with DNA and with haemoglobin	Liver, lungs, bladder Lungs, liver
N-nitroso compounds	N-Nitrosodimethylamine (Drablos et al. 1998)	Form adducts at N- and O-atoms in DNA bases	Liver, lungs, kidneys
Carbamates	N-methylcarbamate esters (Wang et al. 1998)	Chromosome aberration, gene mutation, cell transformation	Experimental results showed liver, kidneys and tests degeneration
Halogenated compounds	Trichloroethylene (Lock et al. 2007)	Somatic mutations, modification of cell cycle pathways	Experimental results showed kidney, liver and lung cancer
Natural carcinogens	Aflatoxin B1 (Wild et al. 1986) Asbestos (Luch 2005)	Forms adducts with guanine, react with RNA and proteins	Liver Lungs
Metals	Arsenic (Shi et al. 2004) Cadmium (Hartwig et al. 2002) Nickel (Costa et al. 2003)	Oxidative stress Inhibit DNA repair pathways and nucleotide-excision repair Histone acetylation and DNA hypermethylation	Skin, lungs, liver Lungs, prostate, kidneys Lungs, nasal cavity
Anticancer drugs	Alkylating agents (Luch 2005)	Interstrand and/or intrastrand cross-links	Leukaemia

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogenic agents

Biological

- parasites: *Schistosoma haematobium*
Clonorchis sinensis
- viruses: *HTLV 1, HIV*
Herpes simplex 2. típ.
Eppstein-Barr, Hepatitis B
Human Papilloma
- bacteria: *Helicobacter pylori*

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogen Risk Assessment

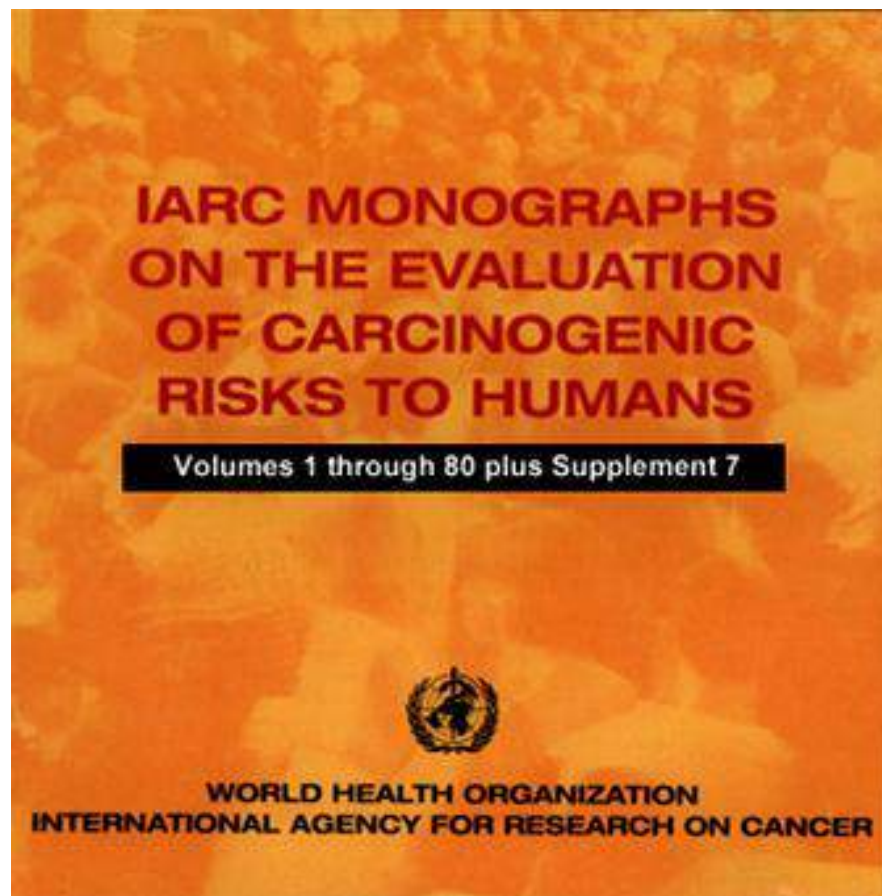

MAK Commission	TLV Commission	IARC	European Union
A1 Human carcinogen	A1 Confirmed human carcinogen	1 Carcinogenic to humans	1 Carcinogenic to humans
A2 Animal carcinogen	A2 Suspected human carcinogen	2a Probably carcinogenic to humans	2 Should be regarded as if carcinogenic to humans
	A3 Animal carcinogen		
B Substances suspected of having carcinogenic potential		2b Possibly carcinogenic to humans	3 Cause concern for humans
			3a Well investigated
	A4 Not classifiable as human carcinogen	3 Not classifiable as human carcinogen	3b Insufficiently investigated
	A5 Not suspected as a human carcinogen	4 Probably not carcinogenic	

Carcinogen Risk Assessment

International Agency for
Research on Cancer (IARC)

Centre International de
Recherche sur le Cancer (CIRC)

IARC, 150 Cours Albert Thomas, 69372 Lyon CEDEX 08, France
Tel: +33 (0)4 72 73 84 85 - Fax: +33 (0)4 72 73 85 75

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogen Risk Assessment

Group 1 — The agent is carcinogenic to humans.

- sufficient evidence of carcinogenicity in humans
- sufficient evidence of carcinogenicity in experimental animals

Group 2A — The agent is probably carcinogenic to humans.

- limited evidence of carcinogenicity in humans
- sufficient evidence of carcinogenicity in experimental animals

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Carcinogen Risk Assessment

Group 2B — The agent is possibly carcinogenic to humans.

- limited evidence of carcinogenicity in humans
- less than sufficient evidence of carcinogenicity in experimental animals

Group 3 — The agent is not classifiable as to its carcinogenicity to humans.

- evidence of carcinogenicity is inadequate in humans
- inadequate or limited evidence of carcinogenicity in experimental animals

Group 4 — The agent is probably not carcinogenic to humans.

- evidence suggesting lack of carcinogenicity in humans and in experimental animals

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Dysfunctions of the immune system

- inhibition → immunosuppressive effect
PAH, heavy metals, alkylating agents,
organophosphates
- stimulation → hypersensitivity

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

➤ The mechanism of allergy induced by chemicals

- ♦ Independent of the dose
- ♦ First meeting with chemical agent
 - chemical agent (hapten) + protein binding
 - ⇒ antibody production (7-14 days)
- ♦ Repeated meeting with chemical agent
 - chemical agent + antibody
 - ⇒ allergic reactions
 - hives, dermatitis, oedema, breathing problems

Allergic chemicals

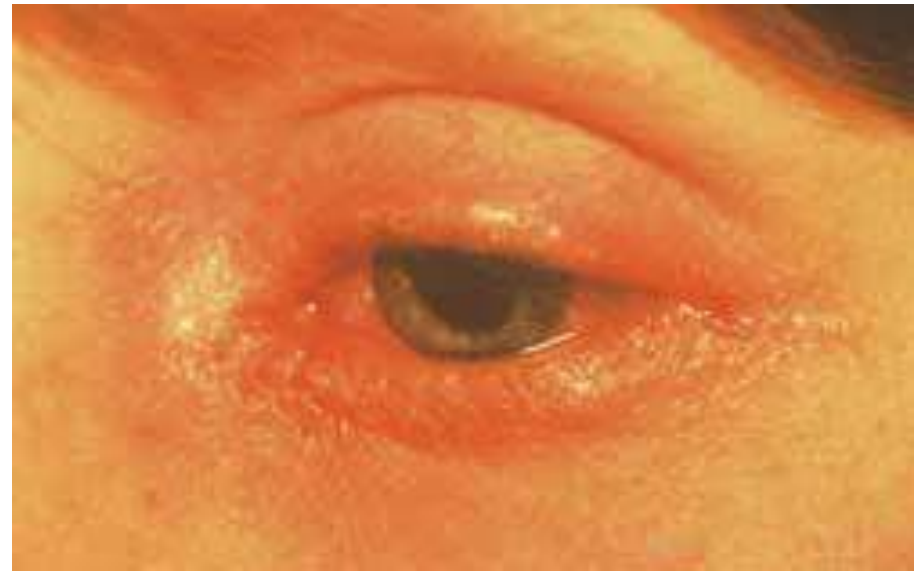

drugs (e.g. salicylates), pesticides

TÁMOP-4.1.2.A/2-10/1-2010-0012

A projekt az Európai Unió támogatásával, az Európai Szociális Alap társfinanszírozásával valósul meg.

Allergy induced by chemicals

Normal larynx

Laryngeal oedema
